The only conclusion to be arrived at is that there yet remains much to be done in proportioning the motor size to the load to be carried. This is particularly true in small-capacity delivery wagons where the motor capacity is often twice or perhaps three times too great for the actual work to be done. Such ill-proportion of work to power is poor engineering, but it is generally to be found in vehicles where a motor from a passenger car has been fitted in the chassis for delivery work. Generally with such a vehicle there is a speed nearly as great as in a touring car. On the other hand builders of high-capacity trucks have generally set out to develop a motor for those particular conditions.

Simplifying the Gearshift

THE electrical gearchanging attachment and also the mechanical device for the same purpose give promise of being factors of more or less consideration in the 1914 models. One car-building concern announced some weeks ago that it had tried out and conclusively convinced itself that the changing of speeds by electric means instead of the side lever or the pedal was a big improvement and particularly so with city travel. This concern uses a relatively small motor, one in which it is necessary to change gears much oftener than with a high-powered car. One or two other concerns are now contemplating attaching mechanical gearchanging arrangements which will entirely eliminate work so far as the driver is concerned other than pressing of a button on the steering wheel.

It is doubtful exactly where the electrical and mechanical gearchanging apparatus originated; perhaps the self starter, the self-lighter for acetylene headlights and the press button for electric lights impressed the inventor with the one thought of eliminating labor to the greatest possible extent and make car driving as great a luxury as possible so far as the driver's work is concerned. It is quite true that the electrical or mechanical gearshift will be welcomed by women drivers, many of whom have discovered how tiring the constant shifting of gears is, particularly when some of the garments interfere with the free movement of the body as needed for gearchanging on some cars. To such the new devices will be a friend in need and leverless gearshifting combined with selfstarting, demountable rims or wheels and simplified lighting should bring the automobile nearly as close as possible to simplified control.

There is yet one other respect in which the electrical and mechanical gearchanging devices can prove their worth, namely, in that their installation will tend towards more frequent gearchanging. For 7 or 8 years there has been developed a strong sentiment against gearshifting, a sentiment that considered gearshifting a weakness in the car or lack of expertness with the driver. The very fact that the body movement connected with lever gearchanging has been eliminated will be an incentive to the driver to change more frequently.

Horsepower is gradually being reduced. Last year saw a general reduction as compared with 1911, this year witnessed a reduction over 1912. Next season will see the power go still lower. With reduction in horsepower and the using of smaller motors there will be increased necessity for greater gearchanging. The four-speed gearbox will come into more general use as it has in Europe. With the advent of such a regime it is highly important that the work of gearchanging be reduced to the minimum; and if the electrical or the mechanical change device can be installed to give uniform satisfaction and the cost of installation is not out of proportion with the results received, then it is a certainty that such devices will come in for practically as general use as the self-starter of today. The rational will always win out and simplifying gearchanging is a rational step. Hundreds of drivers are unable to change gears without that disagreeable grating noise of the teeth of one gear grinding against those of another when engaging.

Felix Nazzaro Wins Targa Florio Race

PARIS, May 13—(*Special cable*)—Clipping more than four hours from last year's time, Felix Nazzaro in a Nazzaro car won the Targa Florio 2-day race round the island of Sicily, covering the 620-mile course in 19 hours 28 minutes 40 seconds. The race started on Sunday, the first stage of 370 miles ending at Girgente, being entirely over mountain roads, including some very steep gradients.

Thirty-five cars started, including two Fords, a Studebaker and an Overland. At midnight Marsaglia on his Aquila was given second start round the island to Palermo, others going at short intervals. At an early hour a stone broke Marsaglia's headlight, giving Nazzaro, who had started half an hour later, a chance to creep up. Snipe, last year's winner, was unable to finish the race. Numerous accidents happened to machines but no personal injuries are recorded. Eleven cars finished within the 24-hour time limit. The results are as follows:

No. Driver	Car	Time
1—Nazzaro	Nazzaro	19:28:40
2—Marsaglia	Aquilla	20:43:49
3—Gloria	Devecchi	21:48:04
4—Berra	DeDion 8-cyl.	22:22:55
5—Giordano	Fiat	22:26:04
6—Sivocci	Devecchi	22:47:00
7—Lopez	Overland	23:12:47
8—Bordino	Lancia	23:43:45
9—Diana	Isotta	23:46:00
10—Stabile	Minerva	23:59:04
11—Turner	Renault	24:30:00

At the end of the first day Marsaglia had a lead over Nazzaro, Bordino, Giordino. The Overland, driven by Lopez, was the only American car among the sixteen finishers.

NEW YORK CITY, May 13—Theodore Pilette, from Brussels, Belgium, who will drive the Mercedes-Knight car entered by E. C. Patterson, a Chicago sportsman, in the Indianapolis race, arrived on the *George Washington* today with his Belgian Grand Prize racer and will leave at once for Indianapolis, reaching there not later than Saturday. This is Pilette's first visit to America. His Mercedes-Knight car was given a 15-day overhauling in the Mercedes factory previous to shipment and Pilette expects to average close to 90 miles per hour on the Speedway. The motor is a small high-speed type, approximately 4-inch bore by 5.1-inch stroke. It has a piston displacement of approximately 250 cubic inches, and greatly under the maximum of 450 cubic inches permitted in the rules. The car is fitted with Bosch magneto; Mercedes single-jet carbureter, and Rudge-Whitworth demountable wheels. This car uses a double cone clutch, and also the Mercedes double-bevel differential system.

With a gasoline capacity of 35 gallons, Pilette estimates he can travel 720 miles without refilling, so that it should not be necessary for him to stop during the race. He expects that owing to the light weight of the car, approximately 2,000 pounds, and the large size of tires used, he will be able to make the entire distance without a stop.

Pilette's experience as a driver dates to 1904 when he began tricycle racing. In 1906 he drove a 90-horsepower Mercedes in the Ardennes Circuit, but was prevented from finishing by carbureter troubles. He has been in the racing field more or less ever since, although his business as Mercedes agent in Brussels prevents him from following the racing circuit to the same extent that other drivers do.

Only Two Events at Elgin

CHICAGO, May 10—The Chicago Automobile Club and the Elgin Automobile Road Race Association entered into a formal contract last night which insures the promotion of the annual Elgin road races on August 29-30. The prize list has been definitely set and the card arranged.

There will be only two races this year, as against five in 1912. The promoters have come to the conclusion that better results may be obtained by having one race each day and making each a star attraction.

Therefore, this year at Elgin the first day's race will be as important as will the second day's, although the sizes will be different. The same money will be hung up in each and the distances will be the same—306 miles. In each race the prize money will total $2,500, and in addition there will be a $200 cash prize for the fastest lap in each race. On the first day this speed bonus will be given by Ira M. Cobe, former president of the Chicago Automobile Club, and on the second day the money will be hung up by Referee David Beecroft.

The first day's race will be for cars of a piston displacement of 300 inches and under, and the trophy will be known as the Chicago Automobile Club cup. It is the old Cobe trophy given a new name. The Cobe cup, it will be remembered, first was contested for in 1909 at Crown Point, Ind., at the meet promoted by the Chicago Automobile Club and was won by Louis Chevrolet in a Buick. The next year it was contested for on the Indianapolis speedway and was won by Joe Dawson in a Marmon. Since then it has been out of competition.

On the second day the race will be for cars 450 inches and under, and besides the $2,500 in cash the Elgin National trophy will be the consideration. This famous cup has been run for three times. It was won first in 1910 by Ralph Mulford in a Lozier; in 1911 by Len Zengel in a National, and in 1912 by Ralph de Palma in a Mercedes.

Thirty-one for Cyclecar Grand Prix

PARIS, May 3.—Entries have just closed for the cyclecar and motorcycle races which will form the second day's program of the French Grand Prix at Amiens. There are thirty-one machines in the cyclecar class, thirteen of these being of English origin, one a German, and the rest French. The cyclecar race will be run on the afternoon of July 13, the course being a triangular one and a portion of that employed on the previous days for the big cars. Under the racing rules a cyclecar is a four-wheel machine having a cylinder capacity of not more than 1,100 cubic centimeters, weighing not under 385 pounds and not more than 661 pounds. If the body is entirely detachable, the maximum weight may be 171 pounds. Each machine must carry two persons.

PARIS, May 3—According to an official announcement from Turin, Felix Nazzaro has signed an agreement to race with one of the Itala rotary-valve cars in the French Grand Prix at Amiens on July 12. Unable to prepare one of his own cars for the French race, he has offered to steer an Itala for the Itala company. It is believed that a second car from this factory will be handled by Cagno, the winner of the first Targa Florio race. Among the well-known race drivers hooked for the French Grand Prix are Georges Boillot, Coux and Zuccarelli for Peugeot; Albert Guyot and Bablot for Delage; Christiaens and Arthur Duray for Excelsior; Gabriel, Champoiseau and Thomas for Schneider; Victor Rigal, Gustave Caillois, Resta and W. Lee Guinness for Sunbeam, and Opel for the Opel car.

Cleveland Special for Indianapolis

CLEVELAND, O., May 12—The Cleveland Automobile Club has arranged for the third annual Cleveland Automobile Special Train to run from Cleveland to Indianapolis and back at the occasion of the Memorial Day Indianapolis Sweepstakes.

INDIANAPOLIS, IND., May 12—This week will see most of the drivers who are to participate in the 500-mile race at the Indianapolis Motor Speedway, May 30, at work at the speedway, tuning up the cars. The Stutz cars have been at work for some little time. The Henderson will be on the track before long. Bob Burman and his Keeton are here, as are Billy Liesaw and the specially-built Anel. The Isotta team is expected next week. De Palma and his Mercer probably will be here before the end of the week. Word has been received that the Tulsa, entered by oil promoters of Broken Arrow, Okla., has been shipped and is on its way. Clark, the driver, will be here in a day or two. It is not known when the other cars will arrive, but they are expected momentarily.

A. R. Pardington, referee, was in the city a few days ago and expects to return about May 25 to remain until after the race. Plans for the race are well under way. The advance seat sale is up to expectations and local hotels are planning to entertain the largest number of guests in the history of the speedway.

Isotta Cars on the Way

MILAN, ITALY, May 13—(*Special cable*).—Word has been received that the three Isotta Fraschini 36 racing cars that are coming to compete in the 500-mile race at Indianapolis are on their way and will be shipped from Havre on the Lorraine next Saturday. They are in charge of Vincenzo Trucco who is to drive one of them. It is likely that Dave Lewis, well known as an American driver, will act as a relief man for the Isotta team.

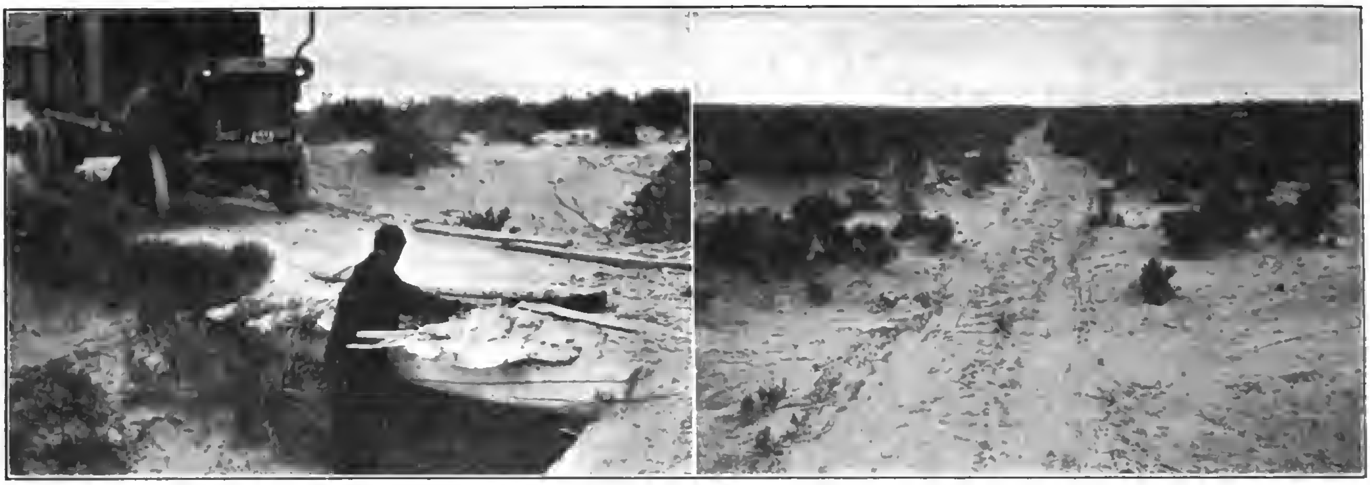
The Indianapolis management has allotted numbers 26, 27 and 28 to the Italian cars. The first number is Harry Grant, the second Tetzlaff's, and the third Trueco. Red and green has been selected as the racing colors in order to get as close to the Italian national colors as possible.

Tacoma Road Races for July 5-6

TACOMA, WASH., May 8—Three road race events will be held during the Montamara Festo, on July 5 and 6 on the roads of Pierce County. Prizes will be hung up to aggregate $10,500. The first event will be the Inter-City Century run, approximately 100 miles over the 3.5-mile course, the prize being a perpetual challenge trophy and $1,500; the second event is the Golden Potlach Trophy, and a cash prize of $3,500; the third event is for the Montamarathon trophy and $5,500 cash. All three races are for non-stock cars.

Hoosiers Pacific Route Fixed

INDIANAPOLIS, IND., May 13—*Special Telegram*—The Indiana Automobile Manufacturers' Association has adopted the following route for the Indiana-Pacific tour leaving here July 1: National road to Terre Haute, Alton way to St. Louis, Missouri state highway to Kansas City, Golden Belt route to Limon, Colo., Utah link midland trail to Salt Lake City, Nevada branch midland trail through Nevada, thence to Los Angeles via Stockton, Oakland, San Francisco and coast road. The cars will arrive at Los Angeles on August 2. The distance is 3540.1 miles; the cars will return by rail. Ray McNamara, in a Premier, will be the pilot.



Left—A large culvert 10 miles west of Kelton supported on logs having their ends laid directly on the earth. A relic of bygone cattle days when much freighting of supplies was done in horse-drawn vehicles. The top has been protected as it weakened, or broke, by a cushion of earth. Since the photograph was taken it has been replaced with a new structure of present day construction. There are not more than four of such and all are replaced with wooden ones.

Right—A sage brush trail that is largely dependent upon automobile travels to keep its lines defined. There also shows the faint markings of a cross trail occasionally used by sheep camp wagons from some far-away ranch. This trail is to be improved for automobile tourists. This section is 15 miles and is part of a 125-mile improvement.

A Transcontinental Hodge-Podge

By Ernest L. Ferguson

Part IV

Salt Lake City to California

FROM Salt Lake City, the Mormon capital, to the California line is 700 miles. It is customary to look upon the California line as the end of a transcontinental trip because the remaining 300 miles to the Pacific ocean are over boulevard roads, with which the eastern motorist is familiar.

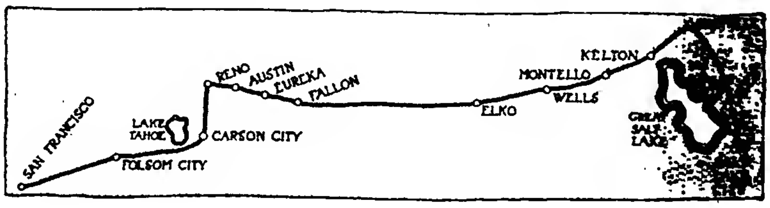
From Salt Lake City to the Nevada-California line, the route roughly divides itself into two divisions: the first one-fifth being through Utah and the remaining four-fifths across Nevada. In looking at the division across Utah, the first one-quarter of it is through a well-settled country; the second quarter crosses a low mountain range; and the last half is foothill country, in which the roads are being improved. In this trip there is a 80-mile stretch between Snowville and Lucin in northern Utah, the country is unsettled, there not being habitation of any nature between these points.

The Nevada section of this trip is over rolling mountain country with a gravelly soil which reaches its mountain climax in the Sierra-Nevadas of the state line. When crossing Nevada you do not encounter any deserts, as desert is understood in the popular conception of the term. It is true that central Nevada has long stretches of country without settlements, the longest of these being 70 miles, between Eureka and Austin, in which not a sign of habitation relieves the eye. The last, or western, third of the state width has settlements all along the roads and the irrigation work is being pushed, so that in summing up Nevada the tourist should bear in mind that the first third of the trip across it is well settled, the middle third without settlement, and the last third well settled.

From the Great Salt Lake to Lake Tahoe on the Nevada-California dividing line the transcontinentalists will find their road comfort is being rapidly improved. Just as to the east and to the west of these two states, there is an awakening appreciation of the value in hav-

Upper—Why one county in Utah is reconstructing a road along the opposite side of the paralleling railroad grade. A series of rains beyond all previous records turned the roadbed into a deep chasm split crosswise by a larger flow of water. The zig-zag lines in the foreground show how alkali mud cracks in baking. Arrows indicate line of old road grade. Circle shows railroad grade.

Lower—Another view, in the opposite direction. On the left can be seen the railroad grade that dammed the rush of water and forced it along the roadway. This railroad grade is now to protect the new roadway to be built to the left of that same grade; this because the shape of the land brings all the water from the right, which is north.



ing tourists go along the way without road difficulties that mar the otherwise pleasant journey.

For some distances around Salt Lake City and Ogden, climate and soil are peculiarly adapted to fruit growing and the success and profits are reflected in the many miles of improved roads and highways. These extend in some measure to the eastward, but are more noticeable toward the north along the country bordering the lake.

Heretofore, following the line of the railroad, transcontinental touring has swung north and west around the lake, encountering difficulties in the overflowed flats that extend some miles from the lake, either from weather or the intermittent tidal rise of the lake. Recently a combination of automobile dealers, newspaper men and hotels have devoted much time to find a way that would obviate the previous natural difficulties. The effort has been successful and now automobile travel is directed northwest to nearly the Idaho state line. In distinction this is called the mountain route. By this it is not to be inferred that mountain climbing makes up the work of the car. The route leads through, rather than over, a small range of mountains, and all grades are gradual and of no great length.

This road has its value in that it is largely surfaced with gravel that has been washed from the mountains for untold ages giving many miles of natural roadbed that is nearly perfect. The thing to be feared is that sometime, in the trend of events, there may come an attempt to construct a highway by tearing up and reshaping the new surface. Bold as the statement is, that would be nearly destruction, as underneath the gravel is that same finely pulverized alkali soil. The most that ought to be done is to provide side drainage for water and snow precipitation, leaving the now excellent surface severely alone.

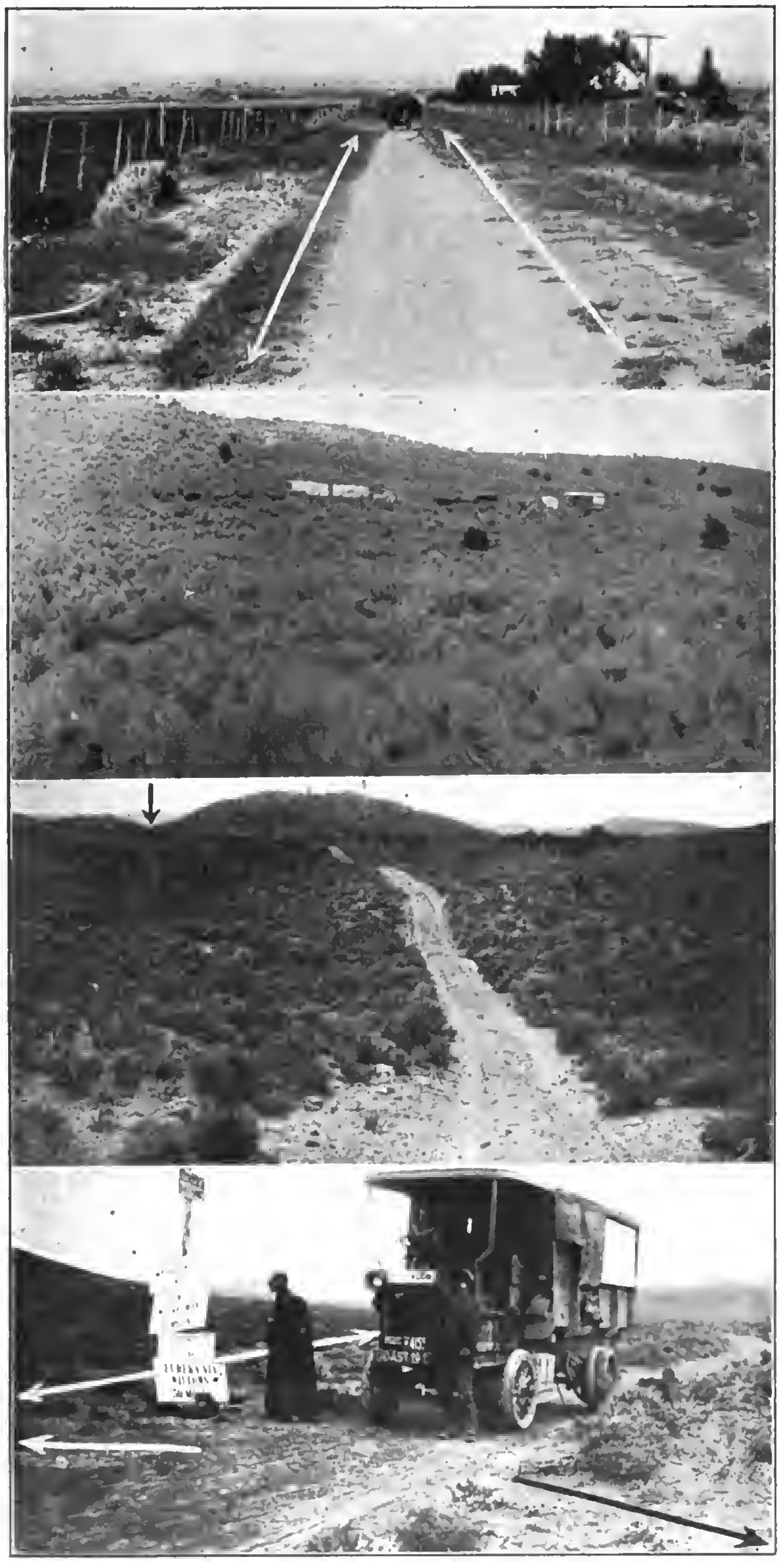
Just south of the Utah-Idaho line the route turns southwesterly until it comes near the extreme northwest arm of the Great Salt Lake where it bends west to again avoid the flats. Then it runs southwesterly finally coming to the old line of railway used before the cut-off was built across the lake, whence it keeps close to the railroad to the Nevada line. This last section carries it along the northern borders of the Great American Desert, but this is necessary to avoid the precipitous ranges of the Raft river mountains.

Upper—The effects of a long series of cloud bursts in the nearby mountains 19 miles east of Lucin. Arrows show original level.

Lower—The straightaway cross and forking trails 12 miles east of Lucin. The straightaway main trail is the one running lengthwise of the illustration. Arrows show trails and a bank.

Left—Starting the work on the new roadway south of the railroad grade in Northwestern Utah. A steel rail, used either in its normal straight line or else bent into V-shape, is pulled by four horses to tear out the sage brush and other growth. For the first attack a straight rail gives a greater strain.

Right—After sage brush has been railed out by its roots to the desired road width, then comes the shaping of the road by crowning for drainage.



Top—A well-kept road in a fertile valley in northwestern Nevada that is irrigated by small streams from nearby mountains. The culverts are narrow—one or two boards wide—and the water shallow, so that upkeep is simple, and a broken culvert does not materially impede travel. At either end of this section are sandy or alkali roads. There is very little rainfall in this section, so that side ditching is not prominent. Arrows show growth wearing away.

Upper Middle—As the tourist turns south toward the middle of Nevada there is a low mountain range to cross. The old road up the mountain has been washed away and the new is yet soft, making the climb slow traveling, particularly after a rainstorm. Horse freighting is slow work, and overtaking automobiles must wait for the one or two turnouts before passing. This scene is 3 miles south of Elco. Arrow indicates road route climbing the Humboldt range.

Lower Middle—Traveling east and west midway the state of Nevada there are stretches of well-defined trails that wind in and out between the low ranges, with now and then a climb to the lowest gap between two crowns. Between Eureka and Austin it is 70 miles and there is nothing but roads such as illustrated.

Bottom—Cross a plain 70 miles between habitations is made a matter of certainty at forking and cross trails by newly painted sign posts erected by the county. It is not unusual to come to groups of six or eight of these signs that are sources of comfort to the strangers not used to magnificent distances. Arrows indicate trails.

This latter portion of the touring road best illustrates the spirit that is alive in the matter of providing roads for the outsider to use. For not less than 125 miles this road is in one county, Box Elder, and recently the county issued road bonds for $175,000 to improve the road up to the Idaho line and then south and west to the Nevada line. The magnitude of this undertaking and the public spirit displayed can be appreciated when it is known that the county has but 14,000 widely scattered inhabitants, and that it is largely a sheep-grazing section—and sheep grazing does not require roads that are graded.

For the last 16 miles an entirely new road line was worked upon during August and September. Heretofore the road in that locality ran north of and alongside the old railroad. This meant that all the wash from the mountains close by on the north swept across the road and, banking against the railroad grade, surged back to the road again, thus doing double destruction. The new road line runs alongside the railroad grade, but south of it. This change was made that the banking of the railroad grade will act as a buffer in rainy weather for the new roadway. Small bridges and culverts have been constructed at logical points, that is, to match those of the railroad.

To Avoid Long Climb

Bending slightly away from the railroad the route now traveled continues by climbing nearly to the top of a mountain, then dips down again to the Utah-Nevada state line. It is part of the county plans to change this line to one that avoids the long climb. To make this change effective it will be necessary for the county across the state line to reconstruct its line of roadway as a continuation. The promise of the county in Nevada has been given the authorities in Utah and work on the change will be carried out during 1913.

Touring across Nevada brings with it several stretches some distances from the railroads. The old trail along with the line of the through railway is not generally used as reports on its character deflects the automobile contingent shortly after entering the state either from the east or the west. However, there is a probable gain to the tourists as the middle half of the trip takes one through several famous mining towns of long standing.

Some Good Roadway

Entering the state from the east there is at first encountered considerable sand and alkali, with later several miles of old railroad grading that furnishes excellent traveling. There is also a long stretch of well-cared-for roadway in a prosperous irrigating section. This irrigation is by many small streams from the near-by snow-clad mountains, and the soil has some gravel in it, also from the mountain sides. This combination tends to give good roads with the least effort which are not affected by the irrigation system, as is the case on the plains east of the Rocky Mountains, where the water is carried in large volumes through great main channels and with soil that is alkali almost throughout.

Soon after entering the state from the east the route turns south to nearly the middle of the state and then turns in an almost direct westerly direction. It is after this latter turning that are the fairly long distances between railroad points.

For the greater portion of this section the natural structure of the soil gives excellent traveling. It is generally a gravelly surface due to centuries of washings from the nearby mountain sides. Like the similar section referred to in Utah, as a touring roadway this would be spoiled by the average method of improving. Rain, in quantity, is abnormal, and the most that ought to be done is to side-ditch the traveled way to prevent the cross-flowing of water.

The erection of guide posts by the counties is quickly taking place, and it is impressive to find them at the forks and crossing trails where towns or settlements of any sort are 70 miles apart. Those counties that are placing sign posts are also improving the mountain climbs by grading, also by widening the turns on the grades, that have in the past been none too easy to negotiate with the long wheelbase which is characteristic of so many of the automobiles designed in America during the past few years.

After three-fourths of the state has been traversed the towns become fairly frequent and near together. The industry of farming is rapidly settling a considerable section and the spirit to improve the roads for intercommunication is evident on all sides.

A Parting of the Ways

When the automobile transcontinentalist has come to Nevada's metropolis, at Reno, there again occurs a parting of the ways that must be chosen before starting for the nearby California state line. Probably the majority decide for the route running nearly west from Reno that takes them through the famous sheds west of Truckee that protect the railroad tracks from snow-slides.

The chief objection to this route by those who have tried this and the other, told below, is the necessity of passing at right angles with their length, through these sheds at the crossings of the railroad tracks. These passages are at sharp inclines and without the possibility of a turn-out from any cause. The sheds completely hide the trains and those who are most familiar with the "blind" conditions send ahead someone of the party to see that a train is not coming through the sheds.

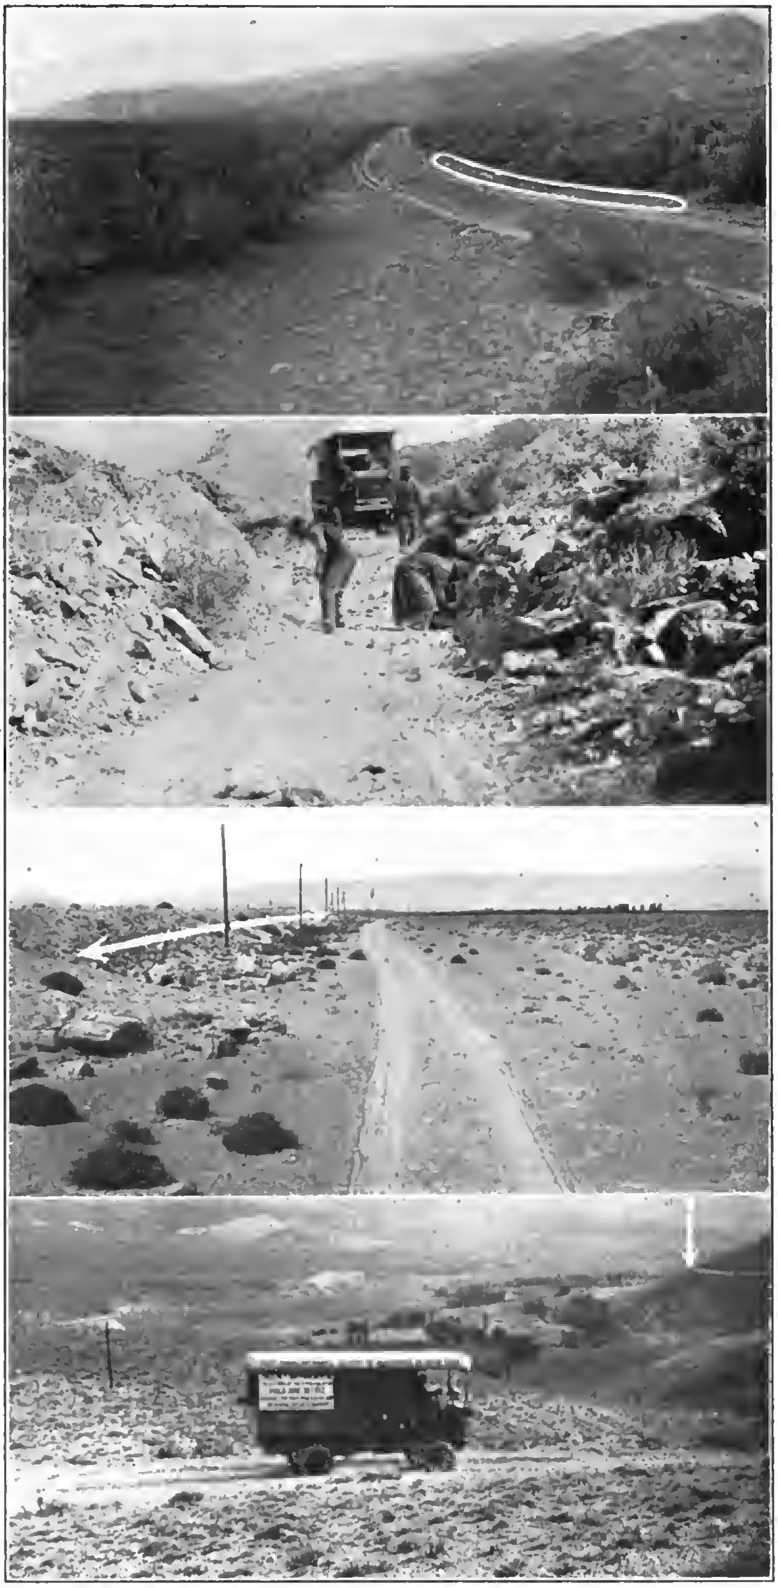
Largely from the lack of information to be secured in the east the other route going south through Carson City is not so well known. Information regarding it is gradually spreading and there is an ever-increasing number who are using it to avoid the snow-shed crossings. Time only will determine which will become the most used route, depending largely on the activity of those most to be benefited in the Capital City. Both routes come together again at Sacramento.

Over the Sierra Nevada

A modern, newly built highway extends south from Reno and is soon to be completed to Carson City. From then on the route is somewhat southwest and crosses the Sierra Nevada Mountains. Coming down from the divide the west state line is crossed at Lake Tahoe. This lake, of over 1,800 feet in depth and more than 6,000 feet above sea level, is thickly dotted with hotels along its boundaries of more than 23 miles in length and 13 miles in width and furnishes pleasant variation in scenery.

By either route climbing the Sierras commences just before crossing the state line into California. That by Truckee is perhaps less in distance, but has sharper grades for short distances. Via Carson City the climb commences in town, and is several miles long, but is quite well graded with few, if any, severe pitches. In either instance the climb is the greatest one encountered in going from the Atlantic to the Pacific, and both present views that are magnificent beyond description.

(*Concluded.*)



Top—Not all sage brush country has clear alkali soil. Now and then there are some stretches with rock in them that give good going. One soon learns to tell in advance the character of the road bed by looking ahead and noting the shade of the sage growth. These shades vary from a dark green to a green that is hardly more than a delicate tint. The deep and light green sage indicates a rather heavy alkali; the medium green a gravelly soil. Area marked in white is covered with stones.

Upper Middle—A particularly narrow canyon that passes the tourist through the Desatoya range of mountains into a valley that was on the old pony expresse route. It is west of Austin and the canyon is 4 or 5 miles long.

Lower Middle—Just naturally good automobiling over a gravelly surface with some rock in the subsoil approaching Wadsworth, Nev. A vast area in western Nevada has been recently opened to irrigation settlement, and where not cut up by the iron tires or horse vehicles the surface gives fair to excellent going. Otherwise, it is deep in sand and alkali. On the left is the retaining bank of a large irrigation main channel. Arrow indicates earth retaining walls.

Bottom—Nearing Reno the roadway, to keep out of the low, wet valley, winds along a bench about half way up the side of the mountains. It frequently makes sudden and sharp ascents and descents with hairpin turns that require good driving ability and brakes in the best condition. Arrow shows where road runs around a "nose" of the mountain.

The Engineering Digest

A Digest of Technical Information from the Engineering Journals

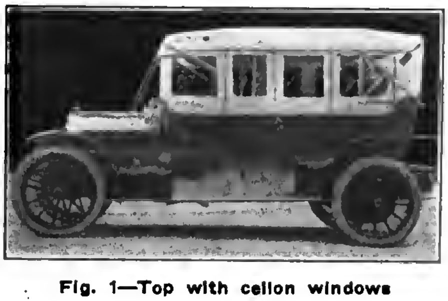


Fig. 1—Top with cellon windows

How Non-Inflammable Celluloid Is Actually Used for Automobiles and Aeroplanes—According to statements from body builders, glass and ordinary celluloid are still the materials used, and the only ones commercially obtainable in this country, for all those purposes in automobile construction for which a transparent sheet is required. Glass panes must be thick in order to minimize the danger of breaking them and wounding those near them with the splinters, and for the same reason the vehicle body, or other structure in which they are framed, must be rigid and heavier than otherwise would be necessary. Celluloid, on the other hand, easily takes fire and burns with great rapidity, and with a shooting flame which is likely to ignite adjacent parts. Naturally its use is limited to safe locations and to the smallest possible areas by which the purpose in view can be ostensibly served. These materials therefore impose a considerable restraint upon the builder's ingenuity, especially in the matter of providing closed vehicles of a very light type, tops which will afford both protection and an unrestricted view of the landscape in rainy weather and windshields which will be neither too heavy nor too delicate and fragile. The accompanying illustration, Fig. 1, shows something of the effect which can be obtained when a tough and non-inflammable substitute for celluloid can be used instead of the ordinary kind. It represents a German Daimler car equipped with a summer top with flexible cellon windows of generous size and number.

With regard to cellon and some of its other recent applications, Dr. A. Rost gives some timely information in *Kunststoffe*, and this journal at the same time sends out a sample of the material, from an examination of which it appears that cellon is slightly less uniform in texture and transparency than first-class nitro-celluloid, and that it burns slowly when a flame is held to it but does not sustain a flame. It shows traces of unsolved cotton fibre at the edge where a portion is torn off. It is softer, tougher and more pliable than a celluloid film. These characteristics may account for the fact that no legislative steps have been taken to make its use for motion-picture films compulsory, in spite of the fire risk encountered with nitro-celluloid films. Another reason may be found in the fact that the cellon material is made by a process patented to Dr. Eichengrün and practically is the basis of a monopoly, so long as other incombustible, or rather uninflammable, celluloid substitutes cannot be produced industrially at a competing price. It is made by a single concern located in Cologne.

Dr. Rost calls attention to the experience that artificial substances which originally are produced in imitation of a natural material, or of one which has been in the market for a long time, rarely get into the competition intended but find their employment in new fields, just because they vary more or less from their prototypes, falling short at some points and excelling them at others. Although Germany, for example, produces more than 10,000 kilograms of artificial silk per day, scarcely a single garment, not even a veil, is probably made from artificial silk alone today. The silk worm culture continues unabated. Galalith, which was intended as a substitute for horn and was made and marketed at first with that purpose in view, has gained its field as a substitute for ivory, ivory nut, wood, onyx and marble. Bakelit was meant to replace copal lacquers and amber but is actually used for cane and umbrella handles and extensively for buttons. Cellon, similarly, does not now seem to threaten celluloid as a material for the numerous household and toilet articles made from this substance but is opening up new avenues for itself in connection with automobiles, motor boats and aeroplanes, in which lines celluloid of necessity has played a very modest part. The possibility of having numerous, large, light and pliable areas of completely transparent material for vehicle tops, boats, awnings, tents and aeroplane bodies, without running the risk of having the entire equipment consumed as the result of a trifling accident with a match or a cigar, has struck a very receptive mood where new effects and conveniences relating to transportation by motor are studied.

Rain curtains hung at the side of the chauffeur and arranged to be rolled up or down, in either case leaving a clear view to the sides, have been found practicable, and for taxicabs and mail wagons strong sheets, from 1 1-2 to 2 millimeters thick, offer a substitute for glass planes which is appreciated not only because the glass is so frequently broken in this class of vehicles but also because the cellon panes can be made larger. Aside from the avoidance of fire risk, they have the advantage over celluloid windows that they do not turn yellow from the effect of sunlight and, being more leathery in structure, the material can be sewed to textiles without difficulties and can be rolled, folded and bent almost like woven goods. It is however in the aeronautic industry that cellon has taken a place for which no other material can even come into the question. Count Zeppelin showed the way in this respect. Cabin windows and windshields for the gondolas of the big airships came first, but the cellon was soon also used as material for side walls and bottoms of gondolas, being strong enough, in the right dimensions, and lighter than aluminum. Its employment in aeroplanes has been of similar nature, and, going further, Professor Reissner in Aix-les-Bains tried in 1910 to use the material exclusively for the frames and membranes of the planes, in an effort to make the whole machine practically invisible at a moderate altitude, and the military aeronautic corps in several countries have carried on experiments with the same object in view. But the results obtained have not as yet been decisive, for cellon is after all only a plastic material, and the toughness it possesses is comparative; its tensile strength is not as high or reliable as that of a fibrous or metallic texture.

By far the most important application of the cellon substance in the art of building aeronautic craft has been found by using the material in solution as a varnish or lacquer for air proofing and waterproofing the silk or canvas employed for the balloon and aeroplane surfaces. Indifferent to castor oil, gasoline and atmospheric influences, including sunlight, as well as to grease, oil and soap, and so perfectly smooth as to reduce air resistance materially, the cellon varnish has had much to do with the improvements recorded in the durability and speed of aircraft. It has been shown that an impregnation with rubber leaves the tensile strength of canvas or muslin practically what it was before and that linseed oil reduces it about 10 per cent., while sizing with starch has a more complicated deleterious influence causing the material to rip readily where a rent is started, and, on the other hand, the aero-technician Dr. Quittner has found by tests that the lacquers produced on the same chemical basis as cellon increase the tensile strength of the textiles a clear 50 per cent. and reduce skin friction about 20 per cent.

These developments in the aeronautic field, to which Dr. Rost refers with more detail, have served to demonstrate the properties of the material for the benefit of the automobile industry, so that it may be tried out in those applications for which it may be considered suitable without the misgivings usually entertained with regard to merely commercial recommendations. Some special uses of the cellon lacquer, as a coating and preservative which may be removed bodily when this is desired, are related by Dr. Rathgen in *Zeitschrift für Museumskunde* for January and have reference to the results obtained by the directors of the royal museums in Berlin. It seems possible that this application may be of interest for the conservation of patterns and gauges made to a high standard of accuracy.—From *Kunststoffe*, April 15.

—

ADAPTING Spring Suspension to Varying Loads.—The knotty problem of devising a spring suspension which will serve equally well for underloads, normal loads and overloads is receiving considerable attention in Europe, especially since the trade in commercial vehicles has grown to respectable proportions. So far no radical solutions are offered, and the palliatives which have been devised have not sufficient scope in their action to span the difference in requirements between an empty and an overloaded delivery wagon or truck. The efforts run in two directions. Either the springs fitted to the vehicle are purposely made so strong or stiff as to support the maximum load or shock, and the loads between minimum and maximum are supported upon auxiliary shackle-springs which must be mounted at an initial tension equal to the minimum load (though this is not always observed), or springs of sufficient flexibility to afford comfort and protection under normal conditions are supplemented with shock absorbers which limit and retard oscillations, under abnormally severe conditions, especially the violent recoil which, without them, the main leaves alone would be called upon to resist. The first system requires shock absorbers, anyway, in order to take care of unusually severe shocks sustained with maximum load, and shock absorbers alone give no static support for overloads and therefore have a reduced range of action under overload conditions. In brief, auxiliaries are for stiff springs, and shock-absorbers are for flexible springs.

One of the latest devices designed to supply something better belongs in the first class and is shown in section in Fig. 2. It is called the M. S. shock absorber but is an auxiliary and adjustable air-spring. The lower cylinder is hung from the upper bolt which is journaled in the end of the leaf spring. The upper cylinder, which works as a piston in the lower, is hung from the lower bolt which is secured to the vehicle frame or the C-spring extending from it. The interior space between them is filled with air whose tension may be regulated to correspond to the load by means of inflation at the air valve V. The bearings between them are so safeguarded with packings and pressed leather bushings M, M that no air can escape from the inside to the atmosphere. Between them there is a small annular chamber C, however, and it is stated that air enters this chamber from the outside through the upper leather bushing when the piston is moved downward by shock or load, the air in C being rarefied by this movement, so as to cause suction. On the other hand, when the spring coil causes the piston to move up again, the air which has thus entered C brakes the recoil movement. It is not stated how the additional air in C gets out again in time to receive the next shock under the same conditions as obtained for the first one, but it seems to be assumed that there is sufficient leakage for this purpose through the upper leather bearing, while the lower one remains tight under all conditions. It is the idea set forth that a few strokes with an air pump will fit this device for increased loads, but it is evident that the mechanism ceases to operate as an auxiliary spring and recoil check when the tension of the air becomes equal to the tension of the leaf spring to which it is fitted. The lateral rigidity of the mechanism seems to be amply secured, so as to obviate rolling of the vehicle-body and irregular wear and action of the two cylinders.—From description in *La Vie Automobile*, April 26.

—

MASS-PRODUCTION the Source of Perfected Construction.—In an explanation to the general public of the methods by which low price and high quality can be combined in the manufacture of automobiles, Dr. Riedler of Berlin, whose works on the scientific valuation of automobiles have won great renown, succeeds in sketching up a very comprehensive subject in a few illustrated pages, which the layman after all will find it very difficult to understand, since he has no key which will unlock the true meaning of the general term necessarily used in the explanation. But apart from the leading part which personal ability plays in constantly devising new means for reducing cost and enhancing quality in the manufacture of motor vehicles —as demonstrated in all the producing countries but to which the author does not refer—the word picture given by Dr. Riedler comes perhaps as near to representing the facts as any other ever drawn. An attempt is here made to represent the gist of his remarks on a 10 to 1 scale of reduction.

A certain degree of standardization is indispensable as well as a reduction of variety in types of vehicles. To hold on to superannuated, be they ever so time-honored construction forms, where mass-production is contemplated, is a blunder that brings its own punishment. To standardize what is unripe is worse yet. Decisions on these points are heavily fraught with danger but must be taken.

In the making of parts time and cost must be saved everywhere; accuracy and quality must be enhanced at all points. Rigorous organization, perfected machine tools and numerous jigs are necessary. The basis is the stock of raw materials. Each piece in it must be prepared in advance for the manufacture. High-speed-tool steel and machines powerful enough to utilize it to the full are necessary. The specially built machine tools must cut special shapes as rapidly as the general machines cut or mill the standard shapes and surfaces. Many have thought that automatic tools dispense with intelligent handling and choke down the personality of the workman, and they have received no return for their investment when acting on this theory. It devolves upon the engineer to make the new and special tools call out new and higher abilities in the wokman, making him the boss who will drive the machines in his charge to their best.

After the time-saving comes the accuracy. Tools are used which remain accurate under wear. Not only the machines but also the working process must be perfected with accuracy in view. Only mass-production can afford the expensive innovations required. Main parts must be turned with an accuracy of 1/100 millimeter, and some of them still much closer to gauge, while ordinary shops do not work with

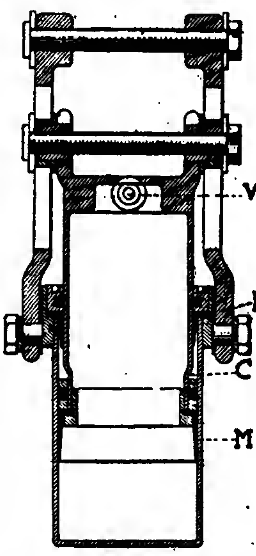

Fig. 2—Auxiliary air-spring adaptable to load

more than one tenth of this accuracy and the unskilled workman scarcely knows 1 millimeter in this sence. Every piece must be measured with the so-called tolerance-gauge, which is a pair of fixed calipers, one made accurately to the min' s and the other to the plus tolerance of the piece. If one will pass, the other must stick. There must also be a testing department independent of all other departments in the production. The men here employed measure every piece over again and throw out those that are not strictly interchangeable with all others of the same kind.

Special fitting and after-work is not to be tolerated. In its avoidance lies the reward for the painstaking control of accuracy. The cost of fitting is excessive and incompatible with economy. It also never results in uniform measurements, and the latter are indispensable for establishing a system and stock of spare parts for replacements. For this reason alone no car should be bought nowadays whose parts are not made interchangeable from the start. Inaccurate parts always cause a heavy upkeep cost to the user. Flaws in materials come in the same class and are avoided by continuous testing in the stock department, independently of the tests made at the steel works. These tests should serve economy rather than fancy.

Formerly difficult parts were cast or worked out of a rough-forged piece. Now castings are practically excluded for working parts, as they do not afford the desired weight-reduction nor the full assurance of strength. Forgings are now brought very close to their final shape before machining, to save waste of costly material and work. To this end, a whole series of dies, presses and drop hammers has to be provided, but the bill for materials is reduced to a fraction of what was required by earlier methods. And the enhancement of quality caused by the mechanical working processes now employed goes hand in hand with savings due to the rapidity of these processes.

The main source of silence in the operation of a car lies in the use of automatic grinding machines by which the teeth of gears, after hardening by heat treatment, especially casehardening, are shaped to perfect accuracy, the accuracy of the curved face of the teeth causing not only the silent running of the gears but also reducing wear to a minimum.

Every test of a motor costs several hundreds of marks which can be saved if saving alone is the object, but these tests and similar ones relating to springs, rear axles and gears explain many differences in the prices asked for the best cars and for those not quite so dependable.

Modern automobile construction has become one in all details highly developed specialty. Unperfected empirics and onesided experience are no longer sufficient. The co-operation of science and experience is as necessary as in all other highly developed building of machinery. The manufacturing facilities can however be utilized in different manners: Either for simultaneous perfecting and cost-reduction of the product or for cheapened mass-production alone, the latter being the main aim in too many instances.—From *Automobil-Rundschau*, April 15. [Reprint of article in new German technical cyclopedia.]

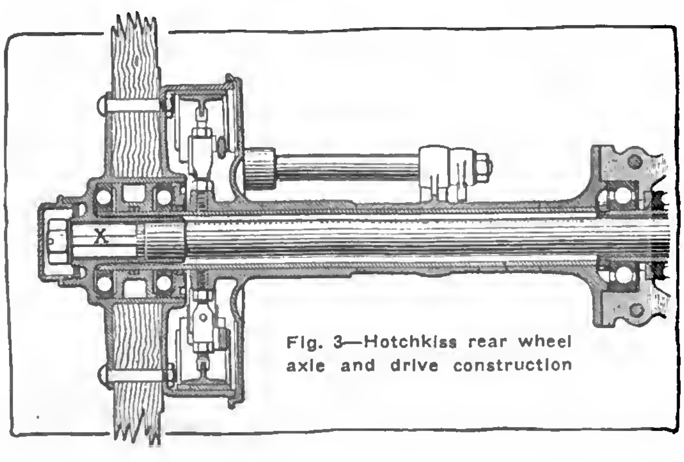

Fig. 3—Hotchkiss rear wheel axle and drive construction

THE Lighting of Shops.—With the different methods of illumination now used in factories, the question of which kind of rays fatigues the workman's eyes most has come to the surface. Many persons believe that the ultraviolet rays are as dangerous as Roentgen rays, especially since it has been proved that they can be used to sterilize water. In reality there is a marked difference, since the Roentgen rays pierce many solids, such as wood and the human body, while ultraviolet rays have only a superficial effect and are absorbed in opaque substances and even in some transparent ones, notably in common glass. The mercury arc lamp emits ultraviolet rays if the tube is made of quartz, and to avoid all danger it is considered advisable in that case to place a glass screen between the tubes and the workmen. If glass tubes are used this is unnecessary, as the glass holds all the ultraviolet rays inside of their walls. For that matter, with quartz tubes, a distance of a few meters neutralizes the effect of the rays, so that such lamps can be used in lofty places where the lamps are hung high. Recklinghausen relates in *Lumière Electrique*, February 22, some comparative tests he has made of the influence upon the eyes of different kinds of light, measuring the fatigue partly by reading and partly by the so-called blink-test which consists in counting the number of times the eyes are blinked in a given time. The red light proved the most fatiguing, the light from incandescent lamps or Auer jets was less so, and the mercury vapor lamp showed a clear superiority.

The automatic closing and opening of the eyelids and the contraction and expansion of the iris, caused by variations of the quantities of light received, or by variations of its sufficiency for the work on hand (this being the most important element in practice) constitute a serious cause of eye fatigue. In order to reduce it, indirect lighting is used, but this is far from being an ideal solution, because the absence of shadows makes it impossible to see distinctly in a room so lighted. Where accurate work is desired it is found necessary to give the light a direction sufficiently definite for producing visible shadows.—From *Génie Civil*, April 5.

PROTECTION for Ball-Bearings in Wheel Hubs.—A construction which goes far toward protecting the balls and ball races in driving-wheels against excessive strains and which also serves to prevent oil from reaching the brake in more than negligible quantity, is noticed in an illustration showing the rear-axle mechanism of a 20-30 horsepower Hotchkiss car—one of those which, though built in France, are sold perhaps mostly in England. The most interesting portion is reproduced in Fig. 3 showing the axle end with wheel and brake drum. The hub has a central tubular extension reaching into the interior of the axle-end, fitting loosely therein, and the wheel-shaft has a shoulder fitting snugly in the extension, while its extreme end X is keyed in the outer portion of the same, in the manner customary for floating shafts. The two ball-bearings are also mounted upon the axle-end in the usual manner, separated however by a ring-shaped piece—with a deep groove for lightness and oil—which acts as a reinforcing parallel bearing, having a slightly larger minus-tolerance, apparently, than the ball bearing, so as to come into action only if stresses upon the ball-bearings tend toward the allowable maximum, and subject to no wear except at such moments. The wood wheel is assembled directly upon the hub, in accordance with modern American practice, and the brake drum forms an integral flange of the inner one of the two hub disks, but the inner disk is the loose one, in this case, and comes last in the assembling. The design suggests powerful hydraulic press work rather than forging as the method of production for all pieces save the wheel-shaft.—From *Omnia*, April 26.

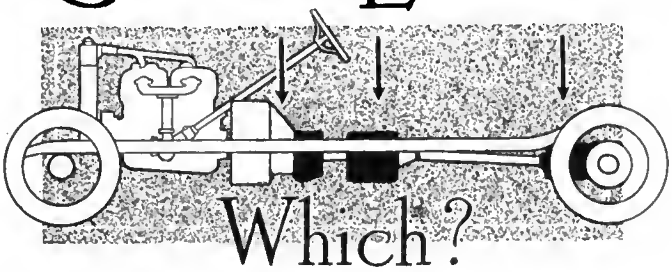
Paving by Motor—Berlin has an 18-horsepower automobile paving machine, the motor propelling the vehicle and also operating six pneumatic hammers which do the work formerly requiring six sturdy workmen, each with a heavy paving ram. Each hammer delivers 90 blows per minute.

The Engineers' Forum

Gearbox Location



Part III

Unit Construction Favored by Four Engineers; Three Prefer Amidship Location and Two Rear Axle

Riker Prefers Location Amidship
Lacy Likes Unit with the Motor
Amidship Plan Appeals to Dorris
Stutz Finds Rear Axle Satisfactory
Rogers Approves of the Amidship Type
Amidship Is Simplest, Says Schwitzer
Felicke Disagrees with Waldon's Views
Bird Thinks Unit with Motor Is Wisest
McCulla Cites His Racing Experience

THIS week the last instalment of the discussion of gearbox location by the leading automobile engineers of the country appears in THE AUTOMOBILE. This topic has been considered from every possible angle in this and the preceding articles and has excited a great deal of interest in engineering circles. Herewith are appended the opinions of nine well-known authorities in the automobile engineering field:

Amidship Best for Big Cars—Riker

BRIDGEPORT, CONN.—Editor THE AUTOMOBILE—The question of gearbox location has something to do with the size of the powerplant you are putting in your car. I think in a small powerplant you probably could combine your engine and your gearset, or you can, if you like, put your gearset on your rear axle. It seems to me when you put the gearset in a car capable of developing 80 to 100 horsepower it is preferable to distribute your weights instead of concentrating them either at one end or the other, and I think it is a fact that the distribution of weight produces an easier riding car. **The car that will hold the road best at high speed is the old double-chain-drive car,** and the car that has the least dead weight on the rear tires, unsprung weight. I know that this has been the opinion of the engineers in designing racing cars when races were held on the roads, to use a double-chain-drive car for that very reason.

Now it seems to me if you want to approximate these same conditions in the shaft-drive car you have to approximate as nearly as possible the design of the chain-drive car. That means take all the weight off the rear axle you can and distribute your weight as well as you can between your front and rear axles. I myself believe in the separate unit system with the gearbox on the chassis frame, possible because we are building a high-powered car; but it seems to me that is the logical disposition of your weight, and while I admit that it probably is not applicable to the lower-priced cars, because it is a more expensive proposition, yet I feel that for **the large powerful car the separate unit system, with the gearbox on the chassis is preferable to the unit system on the rear axle form.**—A. L. RIKER, Vice-President, Locomobile Co. of America.

Make It Unit with Power Plant—Lacy

ROCHESTER, N. Y.—Editor THE AUTOMOBILE:—I am favorable to making this piece of apparatus a part of the power plant unit. There are, of course, arguments for all three of the locations which are to be found on various cars at the present time, but **it seems most reasonable from the writer's standpoint to put the motor, clutch and gearbox all in the same unit.** It has the particular advantage of compactness, and avoids the necessity for universal joints between clutch and gearbox, thereby reducing mechanical complication and multiplicity of parts.

Universal joints between the clutch and the gearbox are the source of more or less annoyance in the way of looseness which causes objectionable rattles. This unit construction as we have designed it permits of very quick removal of the gearbox as it is carried entirely on an annular row of bolts joining the front end of the gearbox with the rear end of the crankcase, there being no rear support. We have used this construction for something over 3 years, and have found it entirely satisfactory.

I object to axle gearboxes as they increase the amount of dead weight on the tires. The weight is on the tires, of course, regardless of the location of the gearbox, but if carried in the chassis, the shocks due to this weight are transmitted to the axle and tires through the springs, thereby reducing wear and tear on the axle mechanism and tires.

Another very desirable feature of locating the gearbox in the chassis, either on the frame or as a unit with the motor, is in that control lever arrangements may be designed to be attached directly to the gearbox, thus making these parts also a unit with the power plant. My 3 years' experience with this construction is convincing evidence to me that it is a most reasonable arrangement both from the standpoint of the manufacturer and the use of the car.—H. V. E. LACY, Chief Engineer, James Cunningham, Son & Co.

Amidship Preserves Alignment—Dorris

ST. LOUIS, MO.—Editor THE AUTOMOBILE—Regarding the question of the best location of the gearbox, my opinion of this matter is as follows:

Every pound of weight in a rear axle, wheels and other unsprung weight, severs as a direct hammer on the tires. These parts will not yield to road surfaces so freely as a lighter axle. This results in the heavy axle hammering the tires more and the springs less than in the case of the lighter axle which reverses this condition. As the springs are practically free from wear and maintenance cost and the tires the biggest item in the cost of operation, the tires should be favored as much as possible.

A heavy axle also consumes more power to vibrate it over the road surface, hence more gasoline is consumed to do the same work, thus increasing the second largest expense item.

The gearbox placed amidship is an improvement on the rear axle location, as it permits of a lighter rear axle. The gearbox being carried on the springs also increases the fixed load to live load carried on the springs, improving the easy swing or riding qualities.

The unit powerplant shares the same advantages with the amidship location over the rear axle location and has the following advantages over the amidship location: It eliminates the necessary wear and renewal of universal joints between motor and gearbox. Perfect alignment of crank, clutch and mainshafts can be maintained. It is lighter construction and eliminates necessity for a subframe. It gives a longer propeller shaft and consequently reduces angle friction and wear of universal joints. It is more accessible, being immediately below the front floor.—G. D. Dorris, Vice-President Dorris Motor Car Co.

Rear Axle Location a Success—Stutz

Indianapolis, Ind.—Editor The Automobile:—We are interested in the present discussion whether the gearbox is more suitable on the rear axle or amidship.

From our past experience we have had splendid success with the gearbox located on the rear axle and we attribute the following reason for our success: For instance, if a gearbox were geared 10 to 1 on low speed and you were using a 40-horsepower motor and developing the full amount of horsepower, which would be 40, your driveshaft and knuckle joints would only be transmitting 40 horsepower with the gearbox located on the rear axle, or if the same gearbox were located amidship or on a unit power plant with the motor these poor little knuckle joints and driveshaft would have to transmit ten times 40 horsepower, or 400 horsepower, in order to perform the same function that they would with rear axle gearbox.

The accessibility of a gearbox located on the rear system and the absence of the grind of the gears being transmitted through the body, etc., with a gearbox located amidship. There is no question in the writer's mind but what there is a decided advantage of having a gearbox located on the rear system.

This outfit, if properly designed, is but very little heavier than the ordinary rear system and we wish to go on record that **we are firm believers in a rear axle gearbox and gearbox unit.**—H. W. Stutz, President, Ideal Motor Car Co.

Amidship Is Most Flexible—Rogers

Racine, Wis.—Editor The Automobile:—With reference to the mounting of the gearbox, would say that we favor the central location because it is very flexible, and there are fewer opportunities for misalignment. It is also more accessible than one connected with either the rear axle or the power plant unit. The gearbox control is more simple than the one requird when the gearbox is mounted on the rear axle, and it also gives better distribution of weight.

Another of our objections to mounting the gearbox on the rear axle is that this construction necessitates an abnormally heavy rear axle.—G. V. Rogers, Factory Manager, Mitchell-Lewis Motor Co.

Unit with Motor Is Wisest—Schwitzer

Indianapolis, Ind.—Editor The Automobile—We are building the gearbox as a unit with the motor because we consider it a better proposition from the manufacturing point of view, as well as from the mechanical aspects.

It eliminates universal joints between clutch and gearbox and allows with the simplest means a rigid dust and oil-tight construction for clutch and shifting mechanism without affecting the accessibility with the proper design.

With center control the number of parts for the latter, as joints, rods, etc., is reduced to a minimum, making a great saving in cost and weight as against the arrangement of the gearbox amidship or on the rear axle. It is an easy matter to attach both pedals and levers to the unit, which can be assembled as a whole and hung this way in the chassis an an ideal assembly proposition.

With the gearbox on the rear axle a great deal of weight is carried directly on the tires, while with the unit powerplant it is all suspended on springs and the material probably not so badly subjected to crystallization.

As to weight distribution, we believe, at least with the smaller cars, that the motor unit construction gives a better-balanced machine. The simplicity and cleanliness of design of a chassis with a unit powerplant which has hand and foot control attached to it and is arranged for straight-line drive with only one universal joint necessary is an appealing feature.

It is true that with the gearbox on the rear axle the strains on universal joints are greatly reduced. But as the weights on these parts are not very considerable and as they have small diameters, with an increase of a negligible amount of material it is possible with the unit powerplant to increase strength and bearing surfaces to give services under all contions.—Louis Schwitzer, Engineer, Empire Automobile Co.

Rear Axle a Bad Location—Felicke

Indianapolis, Ind.—Editor The Automobile:—We do not agree with the views expressed by S. D. Waldon in favor of the gearbox axle. We have the following objections to this construction:

First: It increases the unsprung weight of the car. Mr. Waldon states that the Packard gearbox axle is lighter than any other axles without gearbox used on cars of similar weight and power. While this statement reflects great credit upon the designers of the Packard axle, it misses the point entirely, for if an axle is strong enough now with the gearbox it will be strong enough after the gearbox has been removed and the whole weight of the latter must be considered, therefore, as additional dead weight.

That a saving in unsprung weight is of great value is certain. The rear axle is recipient of all the shocks and jolts caused by the unevenness of the road. It is continually thrown up and down and **as the magnitude of the shocks is in direct proportion on the mass of the axle, they will be smaller, the lighter the weight of the axle.** Every unsprung part has to stand the undiminished force of the road shock and it becomes clear that a gearbox axle with about 85 pounds more dead weight than the average axle will be hard on the tires, wheels, bearings, the axle housing and the road.

The reduction of the unsprung weight has long been the aim of automobile designers. Some have gone even so far as to suspend the differential housing on the frame and to transmit the power by two universal joint shafts to the wheels (DeDion-Bouton and Roland-Pilain); others have taken the weight of the springs off the axle and suspended it on the frame (Lanchester, Edwards and King).

Another bad feature of the gearbox axle is that it exposes the power transmitting parts to the sudden shocks caused by the unevenness of the road. When a car is in motion the speed of the power transmitting parts is in a certain relation to the speed of the car. If, now, the rear wheels drop into a hole or go over a bump, they are forced to roll off in a certain time a greater distance than corresponds to the speed of the power transmitting parts. In other words, the latter receive a certain acceleration or shock. When the gearbox is connected with the motor or placed amidship the gearbox gears are protected by the long propeller-shaft and the blow on the rear axle gears is also made ineffective by the backing of the elastic propeller-shaft. If, on the other hand, the gearbox is connected with the axle, there is no elastic part to give and the parts have to stand the full force of the blow. This is the reason why gearbox axles are notoriously hard on gears and shafts.

Of course, all of these forces can be taken care of by increasing the size of the parts, but what has been gained by carrying the high-speed members back to the axle and using smaller universal joints is more than offset by this.

Besides these, there are many other objections to the transmission axle. The bevel gears cannot be adjusted—the gearbox is very inaccessible when used in connection with the torsion tube, as is frequently done. The floorboards in the tonneau have to be raised to give sufficient clearance, which makes it impossible to get a low car, etc.

For all these reasons we are not in favor of the transmission axle and have adopted the unit power plant construction on our cars.—KARL FELICKE, Chief Engineer, the Motor Car Mfg. Co.

Unit Equalizes Weight Best—Bird

JACKSON, MICH.—Editor THE AUTOMOBILE:—We believe that the unit power plant construction, which incorporates the motor, clutch and gearbox in one housing, is preferable to the practice of carrying the gearbox on the rear axle. **We do not believe it is good policy to put any more weight on the rear axle than is absolutely necessary, because the unsprung weight has such a marked influence on tire wear.** The tire cost is an important factor in the total cost of the upkeep, and we believe that we cannot be too careful in adopting such methods of design as will minimize it.

The gearbox, when incorporated in the unit power plant, is placed in absolute alignment when the motor is assembled, and is never affected by road strains. Any strain which is applied to the power plant affects it as a whole and does not tend to throw the moving parts out of alignment.

We believe that the gearbox control is very much simpler in the case of the unit power plant than with the gearbox on the rear axle, where the shifting rods must be permitted to work freely with the spring action of the car. The unit power plant construction makes the gear-shifting connections shorter and fewer, thus eliminating a great deal of lost motion.

Last but not least, we find that the incorporation of the gearbox with the motor helps to equalize the weight on the front and rear axle. This makes the car ride more easily, and aside from the question of unsprung weight, gives an advantage to the tires.—CHARLES I. BIRD, Engineer, Jackson Automobile Co.

Rear Axle Location in Racing—McCulla

DETROIT, MICH.—Editor THE AUTOMOBILE:—I notice in THE AUTOMOBILE, in the discussions regarding the proper location of the gearbox, that several of your contributors remark that the gearbox is in the best location when it is placed up front, from a racing viewpoint.

I do not quite agree with this, for I have driven a great many high-powered foreign racing cars, both on the road and track, and it is my firm conviction that the proper place for the gearbox is on the rear axle.

If you remember, it was the general consensus of opinion during the 1905 and 1906 Vanderbilt Cup races that the winning Darracq was by far the steadiest car on the road and took the corners with less skidding, etc., than any other car, and with less tire trouble.

It was also remarked during the first 500-Mile-Race at the Speedway that the winning Marmon hung to the track much better than any of the competitors, and with far less tire trouble.

Of course, I fully realize that in the case of the Darracq, the car had no differential; but, then, again, I have never driven a foreign racing car, either chain or shaft driven, that had a differential.

I am not applying any theory whatever to this letter—but it is merely my personal, practical experience.—WM. R. MCCULLA, Assistant Research Engineer, Packard Motor Car Co.

Considerations in Automobile Spring Design

From a Paper Read Before the Society of Automobile Engineers by Leavitt J. Lane

THE ideal automobile spring must fulfill three conditions: first, it must have sufficient resistance and elasticity to support its maximum load without its shape being permanently altered; second, it must be stiff enough to take care of its heaviest work and at the same time be not too unyielding to slight inequalities of the road; and, third, it must decrease the resistance to rolling.

The first consideration in spring design is the steel composition. The ordinary spring steel lacks strength and elasticity and has not the resistance-to-fatigue characteristics of some of the comparatively recent alloy steels. Manganese, nickel, silicon, chromium, vanadium and high carbon steels are used to a greater or less extent, but the best results seem to be given by springs made of alloy steel compositions, such as chromium-vanadium, nickel chromium or silico-manganese. Of these the vanadium alloys are to be preferred. But no matter how good the steel primarily, the secret of the steel spring lies in the end in the heat treatment. A recent comparative table of the physical properties of vanadium and other crucible steels gives the following peculiar properties of vanadium steel. The different steels were oil tempered at 1,500 degrees Fahr. and drawn to 600 degrees Fahr.

	Tensile Strength Pounds per square inch	Elastic Limit Pounds per square inch
Carbon	126,300	101,100
Nickel Chromium	150,300	134,500
Nickel Chromium Vanadium	163,700	152,300
Chromium Vanadium	233,090	210,500

Vanadium steel is practically non-fatiguable and consequently does not become crystallized under the repeated shocks to which a spring is subject. According to one authority, William E. Snow, from one of whose articles the above table was taken, a crucible carbon steel spring was broken at 125,000 alternations of the testing machine, while the chromium vanadium steel spring withstood 5,000,000 alternations and remained unbroken.

In taking up the design of the spring as regards shape, number and thickness of leaves, etc., the use of existing formulas must be regarded as merely a basis for determining just what is required under the known fixed conditions. By experimentation alone can a spring be built most nearly approximating the ideal for its particular case. There are certain fundamental rules which must be followed in all cases, but no formulas can be depended upon to give the best results under the varying conditions of motor car use. A long spring is more limber than a short one. The narrower the spring the more limberness it has. Increase the number of leaves and the stiffness is increased. The more the angle of the spring curvature arc is decreased the stiffer the spring becomes.

In regard to the various types of springs in vogue at the present time, the following table was made up from statistics of recent pleasure car models:

Front springs		Rear spring	
Semi-eliptic	91 per cent.	Three-quarters-elliptic	58 per cent.
Full-elliptic	4 per cent.	Semi-elliptic	19 per cent.
Miscellaneous	5 per cent.	Full-elliptic	8 per cent.
		Three-quarter-platform	10 per cent.
		Miscellaneous	5 per cent.

In commercial car practice there is little uniformity, due probably to the relative recent development of this part of the industry.

Design for Streamline Runabout Body

Body for Edwards-Knight 25 Has Hood and Cowl in Continuous Line—Large Locker Space Provided

By George J. Mercer

A RUNABOUT body design possessing lines that suggest power and speed is shown in the accompanying scale drawings. The chassis to which the suggested design is applied is the Edwards-Knight 25-horsepower model, which has a four-cylinder motor with a bore and stroke of 4 by 5.5 inches, and worm drive. The wheelbase is 120 inches, and wire wheels, 36 by 4.5 inches with Q. D. rims, are fitted. The frame is of the double-drop type which permits the low body position in relation to the hood that is clearly brought out in the side view, Fig. 2.

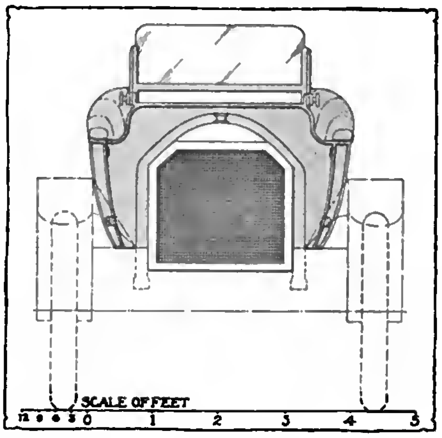


Fig. 1—Front view, showing low position and compact form of body design

It will be seen that the type of body shown adapts well to the chassis, producing a robust and harmonious appearance. The upward slope of the hood permits of the cowl being a continued straight line and the minimum of wind resistance is thus obtained. This effect is also enhanced by the slanted top of the radiator.

The application of wind-cutting surfaces is the keynote of body designing today. Every inch of flat surface eliminated from the front of the car means a considerable saving of power besides having the additional merit of improving the appearance.

The introduction of this feature in body design will be noticed in Fig. 2, and the same idea is carried out in connection with the sides, as shown in the plan, Fig. 3. Flat or obstructing surfaces are avoided by blending the sides of the body into the hood. The body lines are thus continuous in both sides and top, producing a smooth streamline effect.

The sizes of all doors are indicated in the drawings. At the front of the entrance doors there are two good-sized flutings on each side of the body for ventilating, in addition to which there is a ventilating device at the base of the windshield. This ventilator is in the form of a half circle of metal with the ends closed. The lower side is always open, while at the front, there is a door, running the entire length of the opening, that is hinged at the top and is operated by two wing nuts. This door can be opened to any extent desired, and the semi-circular shield serves to deflect the wind under the cowl and away from the faces of the occupants.

This windshield is a new feature used in conjunction with runabouts. The frame that holds the glass extends along the bottom and part way up the sides, the top edge being glass only and free from any obstruction to a clear vision. This windshield as a unit can be swung to any angle, or lowered to lay flat on the cowl. The frame that holds the glass is of wood and is strengthened considerably by the metal that forms the hinge. The ventilating device is integral with the windshield and moves with it.

A commodious locker compartment is provided at the rear. This locker space, the large size of which can be readily noticed by comparison with the pair of suit cases shown in dotted line in Fig. 2, is subdivided, and loading and unloading is by means of three hinged doors, one on the top and one on each side. These doors are made watertight by having copings projecting from the body .25 inch, over which the edges of the doors fit.

Provision is also made for carrying two spare wheels, the body being flattened off at a suitable angle to receive them. The panel on the body at this point is depressed to receive the pro-

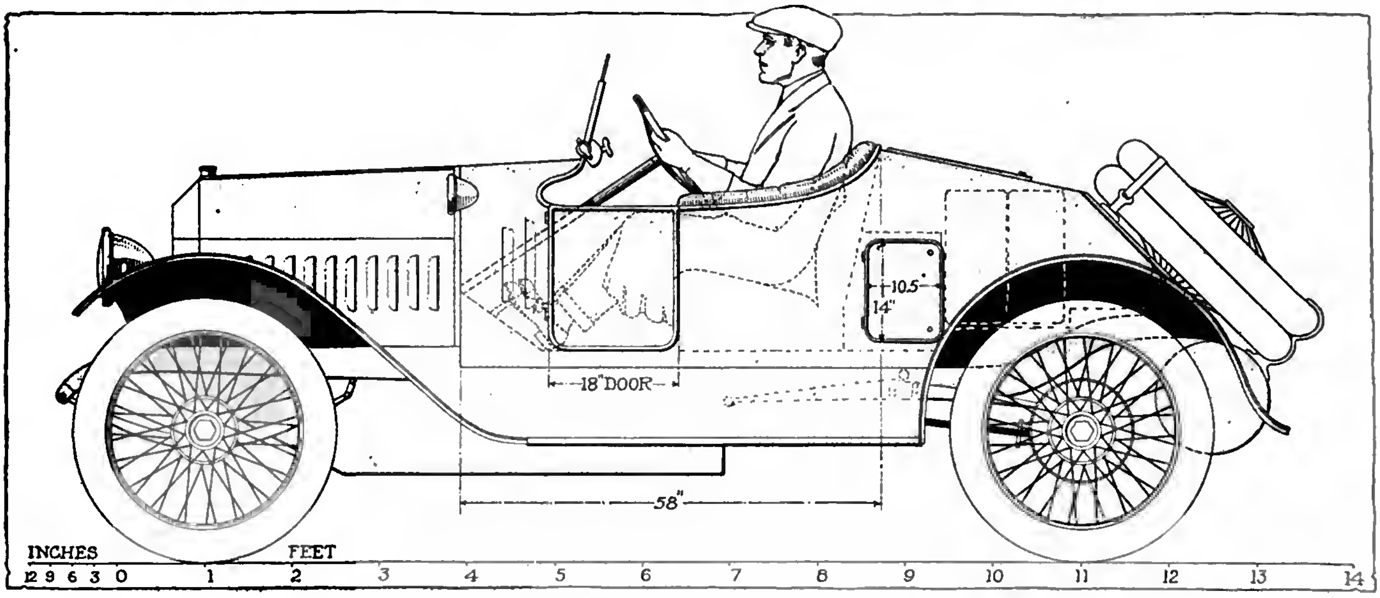

Fig. 2—Side elevation to scale of suggested runabout design adapted to chassis of Edwards-Knight 25

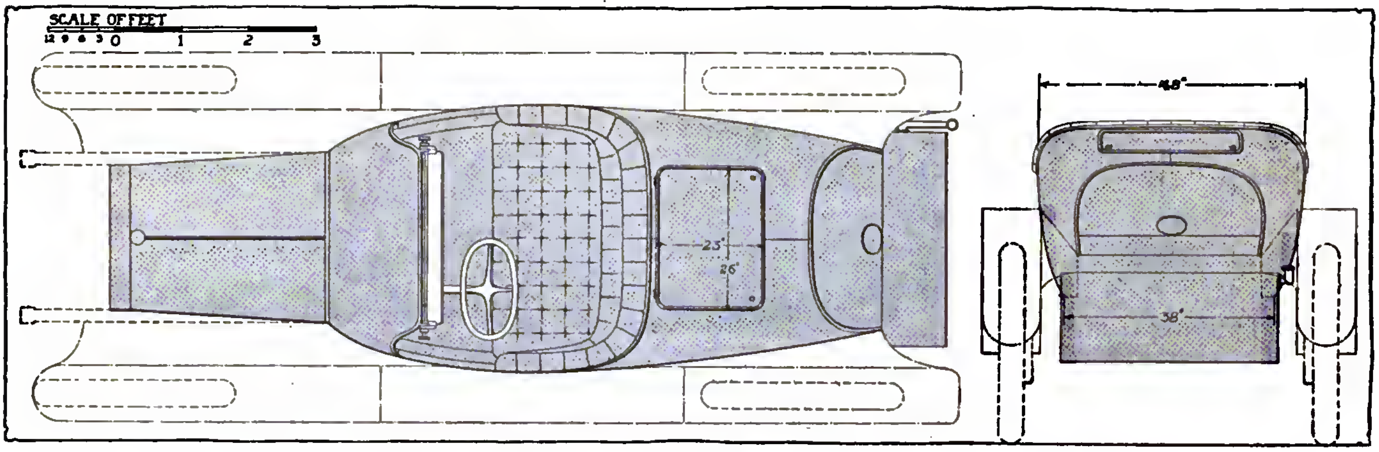

Fig. 3—Plan showing continuous streamlines of body exterior. Fig. 4—Rear view

jecting hub of the wheel. The fastenings are on the gasoline tank and on the body.

For the construction of this body wide sheets of metal are required. The cowl is one piece, forming the two sides and the top and from the dash to the front of the door. The narrow sheet under the door is separate, and is butted between the front and rear sheets. The rear sheet extends from the rear of the door to the back end of the chassis. It is cut off on line with the flat formed for carrying the spare wheels and is then continued up to midway of the top, where it joins the corresponding sheet from the opposite side. This joint is a carefully made butt and the two ends are flush riveted on the outside. On the under side is the customary reinforcing strip that crosses the joint and through which the rivets pass. This joint is not a very long one as the door or lid occupies the greater part of the distance from the seat line to the tire space. After riveting, the joint is carefully wiped with aluminum solder.

The size of the one sheet for the cowl is 74 inches by 18 inches, and for the two rear sheets 70 inches by 53 inches each. All are of aluminum 16 gauge. Aluminum is the most suitable metal for these sheets as considerable hand work is necessary and the extra cost of aluminum over steel is infinitesimal as compared with the added cost of working up steel for the purpose. On the flat sheet at the rear, however, 22 gauge steel can be used to advantage. The joint of this flat sheet with the side panels is covered with a moulding.

On the sides the small doors are cut out of the flat stock, and, as mentioned before, the door openings, both of the side and the top, are reinforced by copings that serve to shut off the entrance of water. The framing inside is of wood, with the necessary iron braces at the entrance doors and under the back end to support the spare wheels. The divisions in the luggage compartment will help in making the top rigid.

This body presents comfortable accommodation for two people, and in order to give a clearer impression of the body proportions relative to the passenger, the figure of a driver 6 feet tall is outlined in Fig. 2.

With regard to painting, although this body is odd in its outline, nothing of the loud in colors should be used. The best combination is the dark blue so much in evidence as the body color with black mouldings and fine hair line striping of lighter blue, together with black leather and black and nickel mountings.

The appointments on a car with this type of body are generally very simple, pockets on the doors being the only part of the trimming of any importance. The horn is placed under the hood and the electric side and headlights and the fenders are standard equipment.

English Limousine Designs Show Novel Features

TWO fine examples of body building, possessing several novel features in design, have just been completed by two well known English motor-carriage builders, Messrs. Mulliner, London, and The Regent Carriage Co., for the Vauxhall Motor Co., England. These are intended for exhibition at St. Petersburg.

The Mulliner product is an inclosed front limousine with a V-shaped front, that is, the wind screen is in two flat planes extending from cowl to hood and meeting in a vertical cutting edge in the center. A reversed bow window divides the front and rear portions of the body. The glasses, which are frameless, are made to slide past each other, as in a circular fronted brougham, and conversation can be conveniently carried on by the friends in the interior. The window on the right of the driver is divided from top to bottom and slides, so that signals can be made to any overtaking traffic. Two occasional seats are fitted under the front seat, and draw out, lifting up into position against the division.

The upholstery is carried out in fine material of grayish-blue tone, harmonizing with the gray sycamore which is employed in the decoration and finish of the upper part and the roof.

The limousine which has been constructed by the Regent Carriage Co. has an interior treated in an entirely novel manner. The front is of the usual open type, with large and comfortable driver's and passenger's seat, and is finished in black leather, the ceiling being finished in dead white. The upholstery is in a pale-gray corded silk, with a faint relief, and is confined to the lower part of the carriage and the center oval of the roof. The oval type of the body is carried out in the arrangement of the interior. The panels of the doors, the front, and the roof take this shape, as well as the rear window and the outline of the flanking cabinets. These contain the usual accessories to be found in an enclosed car, a barometer forming the centerpiece of one panel and a clock that of the other.

The fine wood employed is harewood, relieved with a fine inlay, and the mouldings round the lights and windows are of a very elaborate character and beautifully and sharply finished. The space between the tops of the doors and the centerpiece is filled in with harewood inlay, very highly polished and finished. The centerpiece is a floral design in silk, of the same shade.

In the center there is a roof ventilator, and four electric lamps illuminate the interior. The windows, all of which, with the exception of the rear one, are made to drop, are balanced and held in place by bolt catches. In addition, sun blinds of stout celluloid, with ground faces, are fitted, so that the car can be used with comfort in the most tropical sunlight.—From *The Motor*, England, April 29.

Fig. 1—Driver's daily report card for Locomobile trucks

Locomobile Truck System

Devised for the Vehicle Users' Cost Keeping

ONE OF THE companies who are making intense efforts to increase the operating efficiency of their trucks used for commercial purposes is the Locomobile Co. of America, Bridgeport, Conn. This concern not only conducts an up-to-date service department in the heart of Manhattan, from where all trucks operating in the Metropolitan territory can be promptly served, but in addition has introduced an inspection system and has devised an elaborate cost-keeping system for users of Locomobile trucks. This system, in addition to the demonstrating and inspection report system of the company, is described below.

The user's cost-keeping system comprises eight blanks, the demonstrating system two and the inspection system one. Before taking up the various forms, it should be remembered that while drafted by the Locomobile company for average truck service, the forms do not meet and are not expected to meet each and every specific condition of truck operation; but they will form a good basis upon which truck operators in various lines of business can design their specific record forms.

Following are the eight forms used in the cost-keeping system for the operator of commercial vehicles.

1—Driver's daily report card.
2—Daily truck cost report.
3—Monthly variable-expense sheet.
4—Twelve-months' truck-operation cost record.
5—Comparative record of cost of trucks.
6—Tire cost-record and history blank.
7—Repair tag, front and back side.
8—Stock card of repair parts room.

Taking up these forms in the order above, the first blank is

1. Driver's Daily Report Card—This card, Fig. 1, is 6 by 4 inches, printed on thin white cardboard, black, on one side only. The driver starts the form in the morning when starting from the garage, filling out the date, the time of starting and the odometer reading at that time, as well as the amount of gasoline received; likewise, the oil. He records, during the day, the number of round trips made and the nature of the material carried on the truck, and if there are any accidents, if he is forced to call on anyone's help or labor, if there arises the need of buying some material, he records this on the card. In the evening, when he brings the truck back into the garage for the night, he puts down the time of arrival and the odometer reading at that time. The information compiled by the driver is utilized in making up the second form, namely:

2. Daily Truck Cost Report—Fig. 6 shows a sample form of this kind, printed on letter-size paper so as to fit the typewriter. There are spaces on this blank for entering the daily items given under the headings of Fixed Charges and Variable Expenses. In addition to these, there are spaces for recording the time of start and finish, the odometer readings at these times, the number of round trips, the material hauled and the weight carried in tons; as well as the gasoline and oil received and eventual tire adjustments and their cost. Remarks appearing on the driver's report are transferred to this form. As it has been completed by an office clerk, it is forwarded to the transportation manager or delivery superintendent of the business who scrutinizes all the items and if anything is unusual follows it up. Thus, all waste and inefficiency is promptly discovered and may be remedied in short order, or at least recurrence avoided. Under remarks bonuses paid to the drivers for extra trips are recorded, a practice often used to enhance their efficiency.

Form [illegible]

Fig. 4—Monthly variable-expense sheet. Fig. 5—Comparative record of cost of trucks

3. **Monthly Variable Expense Sheet**—On every day of the month the variable expenses are not only given on the report, Fig. 2, but they are also recorded on the ledger blank, Fig. 4. This latter is 14 by 8.5 inches, ruled red and printed black on white paper. The prices paid on that day for gasoline, oil, grease, supplies, repairs done outside of the company's shop, repair work done in the shop and their total are given; likewise, the number of miles traveled during the day and the variable cost per mile for the day. The number of trips and the tons carried, as well as running, standing and total-operating hours for the day are also recorded. At the end of the month it is easy to strike averages.

4. **Twelve-Months' Truck-Operation Cost Record**—In addition to the monthly variable-expense sheet a 12-month record form is kept for every truck in use by the company. The form, Fig. 2, is of exactly the same size and of similar design as the previous form. The monthly totals of variable expenditure are put down on this form, only the depreciation is recorded by itself on account of the importance of this item, it being a means of gauging the extent to which the truck itself, or its life, is consumed by service. The fixed charges are also given by monthly total, and then all these various items are added, giving the monthly grand total expense. To afford ready balance with the work done by the truck for this work, the miles traveled, tons carried and cost per mile, ton and ton-mile are given; so are the working days of the month and the number of trips made, the hours spent in service, running and standing. Then average values for the year, every month of the year, every day of the month, every mile and every ton-mile are calculated.

5. **Comparative Record of Cost of Trucks**—This sheet, Fig. 5, may be used to compare the operating costs of trucks during

any given period, be it a month, half year or a year. The purpose of this form is to obtain exact information as to the operating values of the several trucks used by the company, which are perhaps of different makes. Thus, there is a space for the make and number of each truck, the variable expense total for the period, the fixed charge total and the grand total, as well as all the other items appearing on the two preceding forms and at the foot of the page are spaces for calculating the averages of each item for the period, on the bases of days, trucks, miles and ton-miles traveled.

6. **Tire Cost-Record and History Blank**—This form, Fig. 9, is designed in the same style as Figs. 2, 4 and 5. One form is used for each wheel of every truck, or rather, for each tire. The make of the truck and its capacity, the number and size of the wheel are noted on the top of the sheet. In the ruled section, the make of the tire used on the wheel, its manufacturer's number, the date of installation and demounting and the mileage got out of it are noted. The cost or price of the tire paid when it was bought is also recorded. In case of an adjustment, if a new tire is obtained from the tire maker on additional payment, the order number, tire number, etc., are recorded. When the new tire is worn out, the mileage is also noted, as is the cost, and by adding costs and mileages for both tires an average cost per mile for the tire is obtained.

7. **Repair Tag**—The truck purchasers are also given repair tags so as to keep track of the cost of repairs and materials and labor used for them. The tag is, of course, needed only where a regular truck fleet is used and a consequently large repair shop and stock of repair parts is maintained. Fig. 10 shows the front side of the tag and Fig. 11 the back side. When a driver brings in his truck in the evening and finds that it is necessary to do any repair or overhaul work, he fills out the front side of the tag. The reverse side is used for a statement of how the instructions given on the front were carried out, together with the cost of the job. The repair work being done, the card is sent to the office the same day, so that on the following morning, when the cost reports for the day past are made out, the cost of the job is included in the expense charged to the specific truck.

8. **Stock Card of Repair Parts Room**—A suitable card designed by the Locomobile company for repair-parts rooms bin and card-files is shown in Fig. 12. This card is 6 by 4 inches, ruled red and blue and printed black. Whenever new material is taken into stock it is entered on the card and outgoing parts are checked off, both on the bin card and file card, which two must always correspond and are balanced at regular periods.

The system used for keeping record of truck demonstrations is also very simple, but fully sufficient to note all important and interesting data. Two forms are used for this purpose by the company.

Fig. 3 is filled out by the driver of the demonstrating truck at

Fig. 8—Office file copy of demonstration report

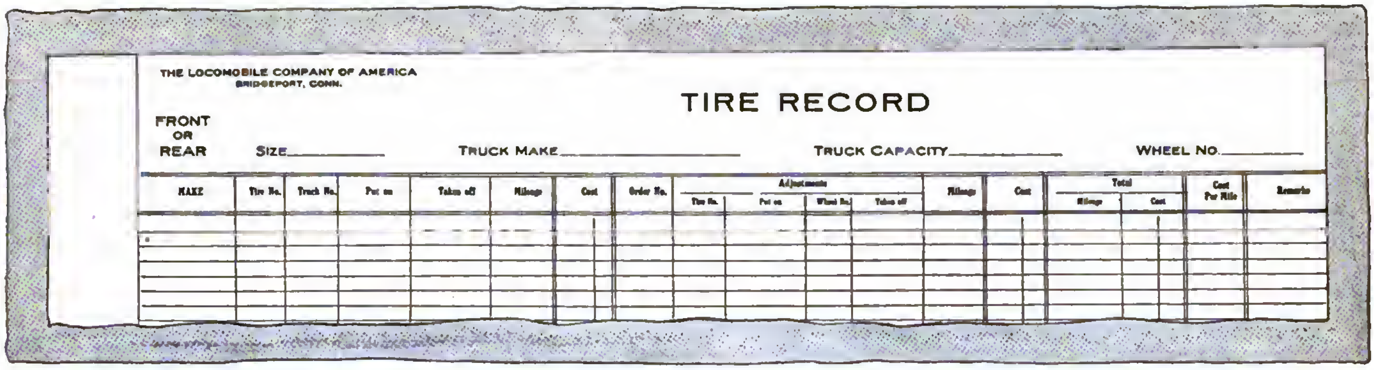

Fig. 9—Tire cost record and history blank

the occasion of every demonstration made. It is 8 by 6 inches, printed on rather stiff tan paper and ruled black. The driver fills out the date, the hour of the demonstration appointment and the name of the company for whom the demonstration is arranged. Then he begins to use the space lined for tabulated work, as he takes up the actual demonstrating work. He fills in the first column with the destination of the first trip, the time of arrival at the point of destination, the time of leaving, and the time spend in unloading and loading. At each place the odometer reading is taken and the length of the way from the previous stop calculated. Likewise the loads are reported. At the end of the day the miles traveled, the loads carried, the time spent in waiting, loading and unloading are totaled. Gasoline and oil received and used during the day are also recorded, as are the weather, the kind and conditions of the road traveled, the material handled, and repairs made during the day. The driver and a representative of the prospective customer sign the card, which is delivered to the office of the Locomobile company when the truck returns to the garage.

In order, however, to have a clean, accessible record on hand in the office at all times, not only are all driver's demonstrating reports kept in a file for just these cards, but a copy is made of every report as a card is brought in by a driver. For this copy, a blank, Fig. 8, is used, which is printed black on a sheet of white paper, 15 by 11 inches. This form is filled in on the typewriter to give a clean, legible statement.

The inspection report, Fig. 7, is filled out by the Locomobile company's inspectors whenever a truck is looked over. Once a month this is done, and the company sends its inspectors out to meet the trucks at their own garages or on the road, where it is more suitable. The inspector, upon reaching the truck, looks over the motor, running gear and all other parts of the car and makes notes of which parts are in good condition and which are requiring attention. This report form is dated and signed.

Dirty Carbureter Causes Trouble—Mysterious Ignition Trouble—Buying Slipcovers Out of Town—Horsepower of Late Sixes—Electric Gearshift Provokes Interest—Likes Rear Axle Gearbox—Defining A. L. A. M. Plug

Trouble Caused by Dirty Carbureter

EDITOR THE AUTOMOBILE:—I have a model 10 Buick, 1909, in first-class condition, equipped with model L Schebler carbureter, Remy magneto, Mosler spitfire breach block plug and is well timed. When running the car idle it will throttle down and will speed up without missing with spark retarded and when spark is advanced half way, but will miss when spark is fully advanced and throttle opened all the way. When running on high gear, the car will run 25 miles an hour without missing with the spark fully advanced but will miss after that speed. If spark is retarded half way the car will run 30 to 40 miles an hour without missing. The car has been running like this for the last 2 years. Engine never knocks, will pull until dead without knocking and will run perfect at 6 miles an hour. Magneto was overhauled by factory last year and new wiring installed on the car; the valves are ground every 3 months; I keep the points cleaned on the timer. The platinum point is not burned on the timer and makes a contact.

Mt. Vernon, Ind. J. ROSENBAUM.

—Your trouble is one of carbureter adjustment, or it might be that the gasoline line is not clean and you may be reasonably sure the latter is the case if you have not cleaned it out during the past 2 years, during which time the trouble has existed. It would be advisable to take the carbureter off, remove the float chamber and clean it out. If you have a screen in your gasoline line, take that out and clean it also. If this fails to give results try a different air adjustment on the carbureter. Should the miss still continue after you have done everything in your power in this direction, consult the Schebler company as to the correct size carbureter to use on your car. It may be that through some error you have a carbureter which is too small.

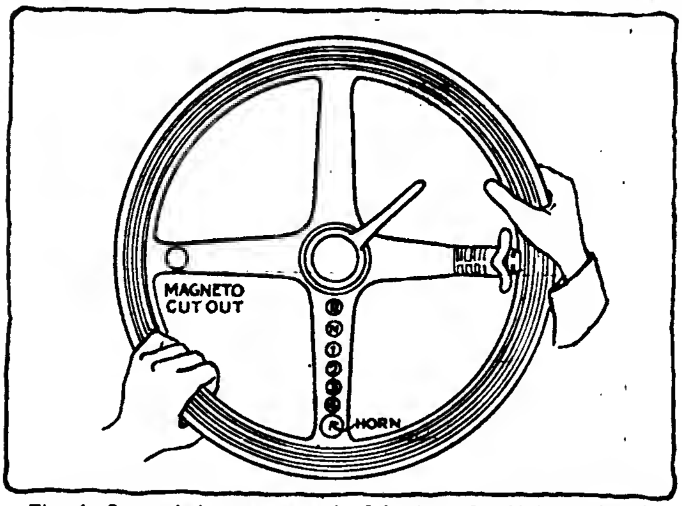

Fig. 1—Suggested arrangement of buttons for Vulcan electric gearshift

Difficulty with a New Coil

Editor THE AUTOMOBILE:—We would like to relate a little experience we had today and ask you what the trouble was. An E. M. F. car of about the year 1909 or 1910 came to have us put on a new Splitdorf non-vibrating coil in place of one of same make that came on the car. We put it on and connected it just as the old one was (by-the-way, the car was running fairly well on either battery or magneto when it came in), and never could get a spark from the magneto, but it ran as well as ever on the battery. As the customer was in a hurry and was afraid of his battery, we put back the old coil and the car went off just as it came in. Now, why wouldn't it run on the magneto the same with either coil? Was the trouble in the new coil? We took it out of the express office for him and think it was direct from the agency.

Bosworth, Mo. BOSWORTH GARAGE.

—The trouble could have been due to either one of two things. First, the wiring may have been incorrect and second there may have been a break down somewhere in the coil. In the first case the probable mistake in wiring would be the connection of the A post on the magneto, the armature, to the ground instead of to the A post on the coil would cause it to run properly on the batteries but not on the magneto. Secondly a breakdown in the switch box of the coil could cause the same thing.

Wants Cloth Slipcover on Overland

Editor THE AUTOMOBILE:—1—Which is correct, carburetor or carbureter?

2—What firms make seat and back cloth covers for Overland 69-T cars? About what is the cost?

3—Can the S. G. V. Vulcan electric gearshift be applied to an Overland 69T, equipped with the U. S. L. lighting and starting apparatus?

4—Would you advise connecting the auxiliary air opening on Schebler carbureter to exhaust pipe in order to get hot air, the fixed air opening being already so connected?

Inman, S. C. C. G. F.

—1—Both methods of spelling are correct.

2—Practically every automobile paint shop in the country has arrangements with some upholsterer where this work can be done. The cost will vary according to the quality of the goods used in the cover. Mohair makes an excellent material for this and you can have a set made up by the Gotham Auto Top Co., of New York City for $45. This concern handles the Overland work and can make the covers from the standard dimensions and ship them to you.

3—The gearshift is made by the Vulcan Electric Devices Co., of Philadelphia, Pa. This company could no doubt fit the device to your car but it would mean that the entire gearset would have to be rebuilt.

4—This would not be a bad idea and would probably give a little higher efficiency in cold weather. In warm weather the difference would not be noticeable.

Horsepower of Late Sixes

Editor THE AUTOMOBILE:—1—What is the mean brake horsepower of the 1914 big six American, 1913 big four Apperson, 1913 big six Knox and 1913 big six Mitchell?

2—Do the Apperson and National companies make six cylinders? If so, what are the dimensions?

3—What is a good weight for a six- or seven-passenger touring car of about 48 to 50 horsepower, A. L. A. M. rating for touring?

Lakewood, O. C. S.

—1—The 1914 big six American develops 65.4 horsepower at 1,000 revolutions per minute; the Apperson develops about 40; the Knox 60 and the Mitchell about 50 at 1,000 revolutions per minute.

2—Neither Apperson or National have a 1913 six-cylinder car.

3—The car should weigh, with the body, within 500 pounds either side of 4,000 pounds. The average is about 4,000 pounds.

Operating Electric Gearshift

Editor THE AUTOMOBILE:—Kindly explain the principle of the S. G. V. electric gearshift. Is it possible to effect a change by pressing number two some time before releasing clutch and have gears shift when clutch is thrown out? That is, if running on third speed and wishing to change to second you press number two before you change. Would the gears shift into second when clutch is thrown out after the button had been pressed when ready to change even after a considerable interval?

Worcester, Mass. J. GLASS.

—The electric gearshift used on the S. G. V. car which was described in a recent issue of THE AUTOMOBILE is operated by a system of solenoid coils which pull the gears into position with a force of 300 pounds. It is impossible to pull two gears into position at the same time on account of the interlocking buttons which are so arranged that only one can be down at a time. If two buttons are pressed at the same time, but one will go down, or if one button is pressed while another is down the latter will jump up. You may press down a button any length of time you desire before changing to the speed corresponding to that button. If you press down No. 2 while you are running in third gear the gears will shift when you press down your clutch regardless if the time elapsing was a week or 2 minutes. If you change your mind as regards the gear you intend to shift to it is only necessary to press down another button and the one which is already in position will come up.

Arrangement of Shifter Buttons

Editor THE AUTOMOBILE:—I am sending a suggestion, Fig. 1, for a better arrangement of the buttons on the steering wheel of the S. G. V. The correct position of the hands when driving makes it more convenient for the driver to reach the buttons than in the arrangement used by the S. G. V. company

Mokelumne Hill, Cal. CLIFFORD H. MEAD.

—The arrangement of the gear shifter buttons on the demonstrator model of the S. G. V. car is shown in Fig. 2. This arrangement is used on the first few cars that were equipped with the electric gearshift. The regular arrangement will be that shown in THE AUTOMOBILE for April 3, page 778.

Likes Rear Axle Gearbox Best

Editor THE AUTOMOBILE:—I am in favor of a gearbox mounted on rear axle as close to differential as possible. From the scientific side, the universal joint and propeller shaft have only the strain delivered direct from engine and not multiplied or stepped up, through the gear ratios in the transmission. Another advantage, the transmission is away from any underpan and any noise in same is not as perceptible as when mounted on motor as a unit. Transmission on motor as a unit makes an easier assembling proposition in building up chassis, but fastens more or less noise direct on motor, and gear noise is very apt to be telephoned to different parts of motor, especially where fly-

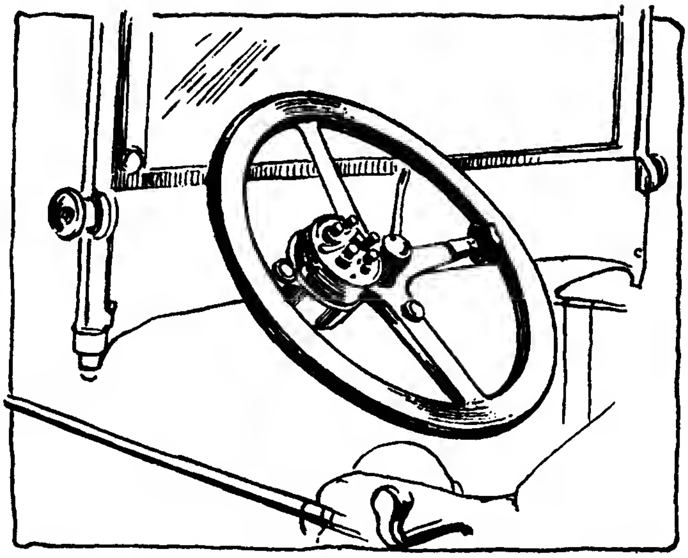

Fig. 2—Arrangement of buttons for Vulcan gearshift on S. G. V. demonstrator

wheel is incased. If forced to have a unit with motor, would prefer to arch around, and leave flywheel open with universal joint between transmission and flywheel. Transmission amidship is good construction but a little harder to assemble and line up, but has some good advantage also.

Connersville, Ind. E. M.

Dimensions of A.L.A.M. Thread

Editor THE AUTOMOBILE:—1—What is the difference between the A. L. A. M. standard, half inch, and the metric spark-plug threads?

2—Where is the safety spark gap on the Ford ignition system?

3—Did the Ford Motor Car Co. ever use a brush in its timer instead of a rolling contact?

4—On a 22.5 horsepower A. L. A. M. rating, could the horsepower be increased as in the Ford model 7, by putting on a larger flywheel, leaving the magneto out?

Nora, Neb. A MOTORIST.

—1—The .5-inch spark-plug employs the regular .5-inch gaspipe thread, which is a taper thread. The old A. L. A. M is a .875-inch straight thread with a gasket top There is a .0625-inch allowance for the gasket at the top of the plug above the thread. The metric thread, which is used to a large extent in foreign cars, is 18 millimeters or .7087 inches in diameter and has a pitch of 1.5 millimeters or .059 inch. The A. L. A. M. has now passed out of existence and the .875-inch straight-thread plug has been adopted as the S. A. E. standard. The plugs now in most general use in this country are the .5-inch gaspipe and the S. A. E. standard, but the latter is being gradually adopted as the preferred type.

2—There is none.

3—No.

4—The horsepower developed by the motor would not be increased but the magneto would not be there to absorb the power necessary to create the electric energy to form a spark. This would give a slightly greater output to the road wheels if you cared to run on batteries. This would be a very foolish move, however, as is no doubt self-evident. The power absorbed is so small as to be unnoticeable and the batteries should only be used in starting or for emergency equipment.

Knocks While Running Idle

Editor THE AUTOMOBILE:—I have a Ford car which I had overhauled last winter. The repairman tightened up all bearings. After running a while the motor developed a knock when running idle. It does not knock when running fast. What do you think causes this knock?

Jacksonville, Ill. J. A. HASP.

—There is a possibility that the spark is too far advanced and

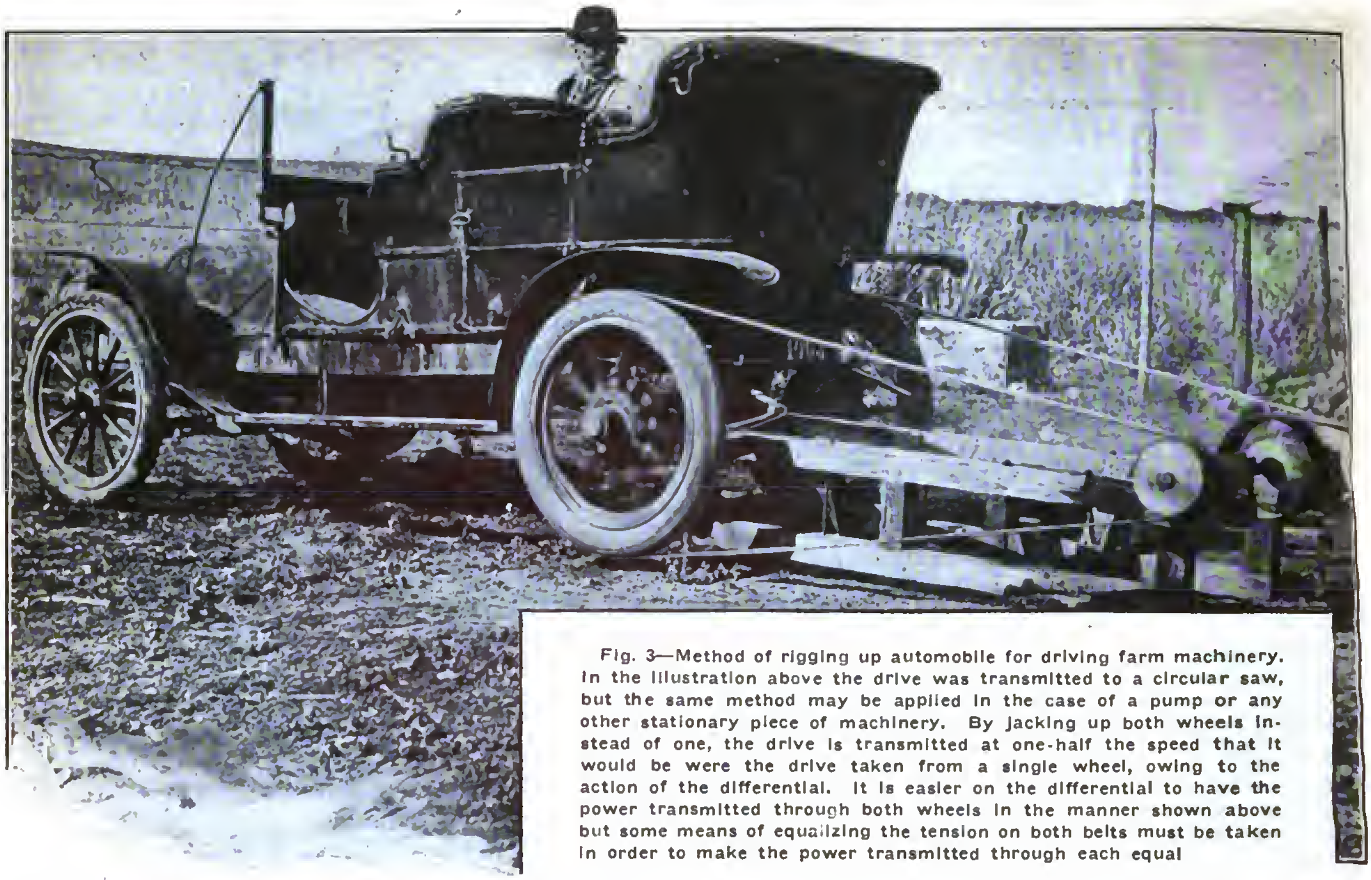

Fig. 3—Method of rigging up automobile for driving farm machinery. In the illustration above the drive was transmitted to a circular saw, but the same method may be applied in the case of a pump or any other stationary piece of machinery. By jacking up both wheels instead of one, the drive is transmitted at one-half the speed that it would be were the drive taken from a single wheel, owing to the action of the differential. It is easier on the differential to have the power transmitted through both wheels in the manner shown above but some means of equalizing the tension on both belts must be taken in order to make the power transmitted through each equal

that you do not get sufficient retard for idling. When the motor is idling the spark should occur very late or the knock is bound to occur. There are many other possible causes for the knock besides the faulty ignition timing outlined above. The trouble might arise from a piston slap, a loose connecting-rod bearing, a loose main bearing, a short circuit, a carbon point or many other causes which may be of an indirect nature and which would never be suspected.

Wants to Change Bendix Drive

Editor The Automobile:—I have a Bendix car of the vintage of 1908 which can still give good service on bad roads but is noisy and needs frequent attention in its transmission box. I desire to change it from a double disk to a single disk drive, connecting the one disk direct to the engine. To make this change it will be necessary to have but one jackshaft, which must have a differential. The method of sliding the one disk to engage or disengage the power must also be altered. The shift can readily be placed on the other side. Your assistance is desired in giving me the name of some maker of jackshaft differentials and devising some way to slide the disk on its shaft. The car weighs 2,350 pounds, hence a differential like that used in the Metz car is too light to stand the work. Plan view of the Bendix chassis is herewith inclosed.

Fulda, Minn. H. Emil King.

—The best course for you to pursue would be to purchase an entire transmission unit from one of the concerns specializing in this kind of work. To attempt to design a new friction set and then to have it made up specially for your car would be an expensive undertaking and would not be justified. The nearest large concern to you which specializes in this kind of work is A. O. Smith Co., Milwaukee, Wis.

Carbon Deposits Due to Gasoline

Editor The Automobile:—I see so many of the oil companies advertise that they have an oil that does not cause carbon and this has led me to believe that there must be other causes for the carbon annoyance to which we are all submitted. Could the Rostrum give some information on this?

2—Does poor scavenging affect some of our modern automobile motors?

New York City. Reader.

—1—Carbon accumulations are frequently due to gasoline. In the past there has been so much talk about the cracking of the lubricating oil and the formation of a deposit of carbon out of the same, that automobilists generally labor under the false impression that the excesses of carbon, of which they so justly complain, are entirely due to the use of poor oil, or the flooding of the cylinders with the same. It is highly improbable that a pure hydro-carbon lubricating oil will deposit carbon in the combustion chamber space in sufficient quantity to give any trouble at all. If the lubricating oil is adulterated with resinous oil there may be some cause for complaint. Automobile gasoline is at the bottom of a large percentage of the carbon trouble. it being the case that this type of gasoline volatilizes but slowly at best, and, unfortunately, it is a fault of carbureters in general to deliver an excess of gasoline at the higher range of speed if the amount of the gasoline is in the right proportion at the low speed. For the purpose of illustrating the lack of volatility of automobile gasoline all that is necessary is to take a blow-torch, fill it with automobile gasoline, light the torch in the regular way and set it down in front of a plate at a distance of four or five feet from the same, and then by turning on the gasoline so that it squirts out with considerable pressure it will be found that the more volatile fractions of the liquid will burn, and the less volatile parts will strike the plate and fall down to the ground without burning at all. If this less volatile product is collected in a pan until there is a considerable amount of it, and it is then allowed to cool off, as a further proof of its non-volatile properties a piece of newspaper may be set on fire and thrown into this pan of liquid, only to find that it will quench the flame. The non-volatile part of the average automobile gasoline mixture is not far from 50 per cent. of the whole content.

2—Incomplete scavenging is at the bottom of some of the poor performance of motors. The time available for the removal of the products of combustion after the power stroke in the motor is too short to permit of complete scavenging in any case. How to realize the best possible condition of scavenging is the remaining problem. In view of the fact that the piston does not sweep the whole space, some of the mixture, after it is burned, must depart under the force of its terminal pressure. After the terminal pressure dies out the part of the gas that is usually left behind is that which accounts for the bad scavenging relation complained of. It has been found in practice that the scavenging condition may be improved by using a small-diameter pipe between the transfer port on the exhaust side of each cylinder of the motor, and a receiver. In this plan, owing to the small diameter of the connecting pipe, the speed of the departing exhaust product is accelerated, and the exhausting "fluid' is compacted, and not unlike the performance of a "comet," the gas molecules persist in accompanying each other on the journey, and the tail of the gas body (comet) follows the head, and in this way the rarefied gas in the combustion chamber at the tail end of the exhausting period follows in the train of the departing "fluid," thus more or less completely scavenging the space. It has been found under certain well defined conditions that a vacuum will reside in the cylinder after the exhaust leaves, which vacuum very readily fills with the incoming mixture, and the performance of the motor from the power and thermal efficiency point of view is thereby much enhanced.

Taking Power from Rear Wheels

Editor THE AUTOMOBILE:—In THE AUTOMOBILE for April 3, page 748, I see a cut of a motor truck with one rear wheel jacked up, belted and running a pump. Does it injure the differential to jack up one wheel and use it for power purposes in this way? Do you know of any better way of utilizing a car for running a pump, or any work requiring stationary power? I want to use my car for power purposes occasionally and would like to know the best way to connect it.

Wasta, South Dakota. A. MATHIAS.

—In using either a passenger car or a truck for stationary power plant purposes it is best to take the power from both wheels as shown in Figs. 3 and 4 rather than by jacking up one wheel. If the car is to be used only occasionally for this purpose jacking up a single wheel would be satisfactory and would not be detrimental in any way to the car, but it would be better where the car is to be used very often for this purpose to erect a small plant like that shown in the illustration. The differential gearing is not put to so severe a strain as it is where only one wheel is used, and besides that the speed is kept down to one-half that which it would be where one wheel is used. The action of the differential is such that it doubles the speed when one wheel is held stationary and the other is free to turn. The accompanying illustrations show the car rigged up to run a sawmill, but the principle is the same when applied to the pump. A truck has recently been brought out which includes an attachment by means of which it serves the purpose of a stationary power plant. This is known as the Service truck and is illustrated in Fig. 5. The pulley seen on the rear end of this truck is driven by independent friction drive device which can be thrown in and out at will.

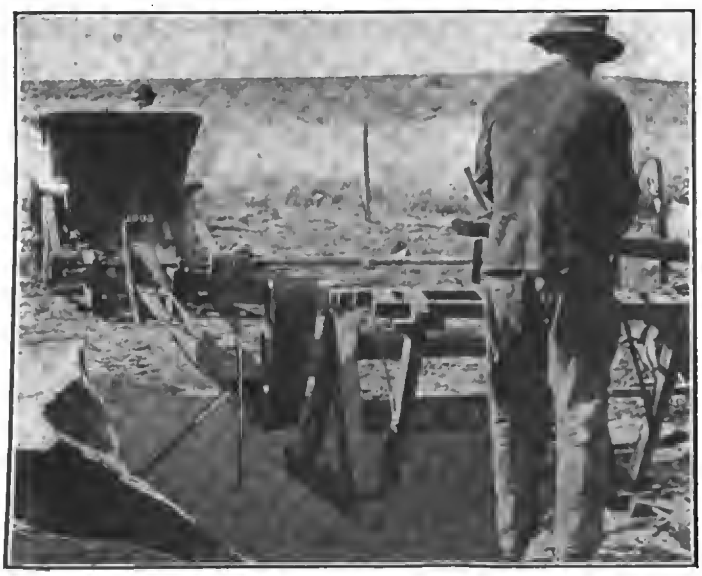
Duryea for the Light Vehicle

Editor THE AUTOMOBILE:—The remarks of Mr. Bourgette on page 906 of THE AUTOMOBILE for April 24, that "There is nothing so fraught with danger to the automobilist as the skid," states concisely a great truth, and Mr. B.'s suggestion as to how to remedy a skid is valuable, provided there is room to put it into effect; but the man who is already on a narrow road dare not turn into the ditch when his rear wheels begin to skid off the road. The cure would be just as disastrous as the disease. It seems to me much wiser to select a construction which minimizes skidding. Every mechanic knows that once the standing friction is destroyed, one part will move upon another easily in practically any direction. A sudden application of power of the brake, or sudden change of direction destroys the hold of the wheels on the road, and the skid begins. What is wanted is some provision which prevents this beginning. My experience, proven by many years of construction, is that heavily-loaded drivers with lightly-loaded front wheels seldom skid. The reason is that the weight on the drivers hold them in contact with the ground, and there is little likelihood that a sudden application of power, or the brake, will start them slipping, because the front of the vehicle is so light that no great effort is required to overcome this inertia. How long will it be before the automobile-using public realizes the many advantages of carrying the load on the propeller and braking wheels? The locomotive builder learned this fact years ago. The cycle rider knows the advantage of a lightly-loaded front, but the automobile buyer refuses to profit by their experience, and continues to use vehicles which are both expensive and dangerous, not only to himself, but to others.

Saginaw, Mich. CHARLES E. DURYEA.

Please Sign Your Inquiries

The Editor of this department is in receipt of several letters which bear no other signature than the sender's initials or some such word as "Reader" or "Subscriber." While the sender's name will not be published if he desires that it be witheld, the signature must accompany the letter. In cases where a quick answer by mail is desired to inquiries, a stamped and self-addressed envelope should accompany the letter.



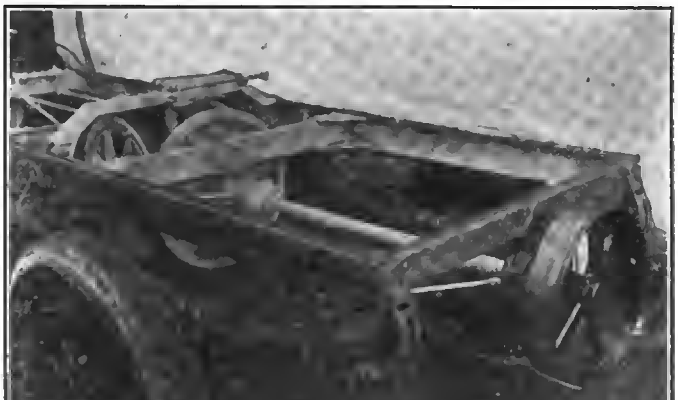


Fig. 4—This shows the method of driving the saw from a central wheel between the two pulleys, through which the power is transmitted through belts from the road wheels

Fig. 5—This truck has a friction drive pulley wheel mounted independently of the road wheels. This permits stationary operations to be performed without jacking the wheels

Vulcan Wins Washington Contest

(*Continued from page* 1011)

No. 5 Wilcox, gross load, 6,260 pounds, U. S. demountable, fronts 36 by 3.5, rears 36 by 4. "Right rear blew out or burst about 7 miles before reaching Hagerstown, noon stop on first day's run. Was replaced following morning in 24 minutes by driver. Second right rear slightly cut."

No. 8 Rowe, gross load, 11,435 pounds, Goodyear side flange demountable, fronts 36 by 5, rears 36 by 3.5, block duals. "Front tires in good shape; rears badly cut and broken."

No. 9 Hupmobile, gross load, 3,120 pounds, Goodyear pneumatic plain tread in front, non-skid tread rear, fronts 35 by 4, rears 35 by 4. "Had one puncture in front and put on Goodrich. One puncture in rear and put on Goodrich."

No. 10 McIntyre gross load, 7,575 pounds, Swinehart side flange in front and Swinehart duals rear, fronts 34 by 3.5, rears 36 by 3 duals. "A few miniature cuts."

No. 11 Autocar, gross load, 7,125 pounds, Swinehart side flange in front and Swinehart cellular in rear, fronts 36 by 4, rears 36 by 4.5. "Fronts considerably cut on treads, rears slightly worn and filled with a number of small stones."

No. 12 Lauth-Juergens, gross load, 9,715 pounds, Goodyear demountable, fronts 36 by 4, rears 36 by 5, solids. "All four tires in fine shape."

No. 13 Atterbury, gross load, 4,720 pounds, Goodyear solid clincher fronts 36 by 3, rears 36 by 3. "Front tires in good shape, rears badly cut from sharp stones. Was undertired."

No. 14 Atterbury, gross load, 6,150, Goodyear side flange, fronts 36 by 3.5, rears 36 by 4. "A few slight cuts in the sides caused by sharp stones."

No. 15 Atterbury, gross load, 7,475 pounds, Goodyear solid demountables, fronts 36 by 3.5, rears 36 by 5. "Fronts in first-class shape. Right rear slightly cut on inside by sharp obstruction. Left rear in fine shape."

No. 16 Atterbury, gross load, 9,650 pounds, Goodyear side flange, with rear duals, fronts 36 by 3.5, rears 36 by 3.5. "Fronts in fine shape. Inside rear dual a little loose at base."

No. 17 White, gross load, 5,175 pounds, Goodrich pneumatics front, Kelly pneumatics rear. Fronts 34 by 4, rears 34 by 4.5. "A few slight cuts in treads, otherwise in fine shape."

No. 18 White, gross load, 7,950 pounds, Diamond pneumatics, rear duals, fronts 36 by 4, rears 36 by 4.5. "Right rear inside tire had bad cover cut; left rear inside blew out near Baltimore; slight cuts in others."

No. 19 International, gross load, 3,675 pounds, Firestone side wire, fronts 42 by 2, rears 42 by 2.5. "Miniature cuts in right rear."

No. 20 Atterbury, gross load, 4,680 pounds, Goodyear non-skid pneumatics, fronts 35 by 4.5, rears 35 by 4.5. "Tires hardly worn, in fine shape."

No. 100 Brown, gross load, 6,780 pounds, Overman cushion, fronts 36 by 5, rears 36 by 5.5. "The inside notches of the tread slightly raised up from the outside, tires generated a lot of heat."

No. 101 F W D, gross load, 7,480 pounds, Goodyear non-skid, fronts 36 by 5, rears 36 by 5. "All tires in perfect shape."

No. 102 White, gross load, 6,630 pounds, Overman cushion, fronts 36 by 4, rears 36 by 4.5. "Tires the same as No. 100 Brown."

The brake tests at the completion of the run were made on a level asphalt street, the trucks carrying the load they had during the demonstration. Each vehicle approached the braking line at its contesting speed. At a signal the foot brake was applied and the distance in feet required to bring the truck to a stop measured. The hand brake was similarly tested. The rules allowed a distance of 50 feet without penalty and imposed one point per foot or fraction thereof for all distances above the 50-foot mark. Only one vehicle was penalized, that being No. 101 Four-Wheel-Drive which had its braking interfered with by the differential between the gearbox and the forward axle being damaged on the last day of the run. It required 74 feet with the hand brake but stopped in 46 feet with the foot brake.

The 50-foot rule in which a truck must stop is a hand-down from passenger car tests. This distance is entirely too great for trucks; in fact, it is questionable if 30 feet would not be a better rule.

The following tabulation shows the distances required by the different trucks, together with the speeds at which they took these tests and the load classification they were under:

No.	Name	M.P.H.	Load	Foot	Hand	Penalty
1	Vulcan	8	4 tons	27	46	0
2	Mais	10	1.5 tons	12	27	0
3	Little Giant	11	1 ton	23	48	0
4	Witt-Will	10	1.125 tons	33	18	0
5	Wilcox	11	1 ton	17	19	0
8	Rowe	10	2.5 tons	14	46	0
9	Hupmobile	12	.4 ton	31	28	0
10	McIntyre	10	1.5 tons	43	29	0
11	Autocar	10	1.5 tons	36	36	0
12	Lauth-Jurgens	10	2 tons	25	33	0
13	Atterbury	12	.75 ton	49	46	0
14	Atterbury	11	1 ton	27	19	0
15	Atterbury	10	1.5 tons	46	28	0
16	Atterbury	10	2 tons	50	36	0
17	White	12	.75 ton	20	30	0
18	White	10	1.5 tons	12	13	0
19	International	12	.5 ton	19	43	0
20	Atterbury	12	.75 ton	45	22	0
100	Brown	12	Persons	39	46	0
101	F. W. D.	12	Persons	46	74	24
102	White	12	Persons	19	27	0

This tabulation shows that the best brake test was made by No. 18 White, making its stops in 12 and 13 feet, but a few inches more than the vehicle's wheelbase.

In addition to a brake test, each vehicle was given a clutch and transmission test. The clutch test consisted in bringing the front wheels against a vertical 8-inch curb. The low gear was engaged and the trucks then required to mount the curb, spin the rear wheels or stall the motor. Vulcan, Wilcox, Rowe and No. 18 White mounted the curb with ease. Witt-Will, Hupmobile, McIntyre, Lauth-Juergens, No. 14 Atterbury, No. 17 White and Brown, Four-Wheel-Drive and No. 100 White, spun the rear wheels, either one or both. The remainder stalled their motors with the exception of No. 20 Atterbury, which had a slipping clutch and was given 5 points penalty under the rules.

The transmission tests consisted solely in seeing that the different trucks could travel on their respective speeds, that is, reverse and all of the forward speeds. Not a penalty was imposed in this test.

The contestants had during the entire road demonstration looked forward to the technical test at the end of the run when all parts of the chassis would be looked over carefully for broken damaged or sprung parts. This examination was made the afternoon following the completion of the run and the work of the technical committee occupied 5 or 6 hours. Few serious defects were discovered, but all were given the penalty as required by the rules.

The following is the complete result of the technical examination with the penalties assessed in each case as well as a day-by-day report of road penalties:

The following is a complete day-by-day record of the penalties that were made on the road. Points were not assessed against loose stove bolts to hold mud aprons in place, there being scarcely a truck without some of these bolts lost or having loose nuts. Manufacturers can make progress in this matter. No knowledge was taken of lost grease cups, if not from vital portions of the trucks. There were three or four examples of cups being lost although there were no cases of lost cups from vital points, what losses there were should be eliminated in future. The record follows:

FIRST DAY'S PENALTIES

Car	Points
No. 1, Vnlcan:	
Repairing broken chain	100
Late 29 minutes	58
Total	158
No. 2, Mais	0
No. 3, Little Giant:	
Took gasoline twice out of controls	6
Took water twice out of control	6
Total	12
No. 4, Witt-Will:	
Working on carbureter	87
Replacing breaker-box	2
Total	89
No. 5, Wilcox	0
No. 8, Rowe:	
Repairing fan belt	44
Motor stall	2
Total	46
No. 9, Hupmobile	0
No. 10, McIntyre	0
No. 11, Antocar:	
Taking water six times	18
Stalled motor	2
Total	20
No. 12, Lanth-Juergens	0
No. 13, Atterbury:	
Taking water	3
No. 14, Atterbury:	
Taking water twice	6
No. 15, Atterhury:	
Repairing broken chain	17
Adjusting carbureter	12
Water, twenty-one times	63
Total	92
No. 16, Atterbury:	
Water, twice	6
Work on floor boards	10
Work on radiator petcock	18
Total	29
No. 17, White	0
No. 18, White	0
No. 19, International	0
No. 20, Atterbury	0
No. 100, Brown:	
Radiator cap. 1; buh cap.; petcock	1
Total	3
No. 101, Four-Wheel-Drive	0
No. 102, White	0

SECOND DAY'S PENALTIES

Car	Points
No. 1, Vnlcan:	
New bolt in fan belt bracket	30
Tightening radiator cap	1
Total	31
No. 2, Mais	0
No. 3, Little Giant	0
No. 4, Witt-Will:	
Adjusting carbureter	3
Work on breather pipe	1
Total	4
No. 5, Wilcox	0
No. 8, Rowe:	
Connecting gasoline line	1
No. 9, Hnpmobile	0
No. 10, McIntyre	0
No. 11, Antocar:	
Replenishing water	3
No. 12, Lauth-Juergens	0
No. 13, Atterhury	0
No. 14, Atterhury	0
No. 15, Atterbury:	
Replenishing water	9
No. 16, Atterbury	0
No. 17, White	0
No. 18, White	0
No. 19, International	0
No. 20, Atterbury:	
Replenishing water	6
Tightening connecting-rods	116
Replenishing oil	6
Total	128
No. 100, Brown	0
No. 101, F-W-D:	
Cleaning gasoline line	15
No. 102, White	0

THIRD DAY'S PENALTIES

Car	Points
No. 9, Hupmohile:	
Leak in gasoline line 11 miles ont of control	8
Adjusting carhureter	5
Total	8
No. 12, Lanth-Jnergens:	
Replenishing with oil	3
No. 17, White:	
Working on carhureter and gasoline line	30
No. 1, Vulcan:	
Fan bracket breaking loose injuring radiator work	10
Replenishing with water	3
Total	13
No. 8, Rowe:	
Cleaning gasoline line and working on same	58
Work	9
Motor stop	8
Total	70
No. 11, Autocar:	
Adjusting carbureter and taking on water	9
No. 18, Atterbury:	
Loose nnt on driving sprocket of rear wheel, work on same	13
No. 15, Atterhury	22
No. 20, Atterhury:	
Working on oiling system	24
Replenishing with oil	3
Total	27
No. 100, Brown:	
Adjusting and cleaning carhureter	19
No. 101, Four-Wheel-Drive	10

FOURTH DAY'S PENALTIES

Car	Points
No. 1, Vulcan:	
Adjusting brackets	12
Water	3
Total	15
No. 4, Witt-Will:	
Adjusting carbureter	22
No. 8, Rowe	28
No. 11, Autocar:	
Water	3
No. 12, Lanth-Juergens:	
Engine bearings work	129
No. 13, Atterbury:	
Replenishing of water and gasoline	6
No. 14, Atterbury:	
Adjusting carbureter and cleaning gasoline line	63
No. 16, Atterbury:	
Water	3
No. 100, Brown:	
Stalled motor	1
No. 101, Four-Wheel-Drive:	
Differential trouble to front axle	272

TECHNICAL EXAMINATION REPORT

Car	Points
No. 1, Vulcan:	
Leaky radiator	20
No. 2, Mais	0
No. 3, Little Giant:	
Hub flange bolt lost	1
Six loose spokes	30
Total	31
No. 4, Witt-Will:	
One water connection leak	1
No. 5, Wilcox	0
No. 8, Rowe:	
Water leak in hose connection	1
Broken fender iron	6
Gasoline leak	1
Total	8
No. 9, Hupmobile	0
No. 10, McIntyre	0
No. 11, Autocar:	
One lost muffler support bolt	1

Broken differential	150
Lost spring hanger bolt	1
Total	151
No. 102, White	0

Horsepower as Basis For Tax Discussed

Majority of Prominent Automobile Engineers Consider S.A.E. Rating as Fair to All Concerned—Many Differ

Several Object to Making Horsepower of the Motor the Basis for Calculating Amount of State Tax

THE article entitled "Cars Taxed on Unused Horsepower," which appeared in THE AUTOMOBILE for March 27, aroused a great deal of interest among automobile engineers, and their letters on this subject have been numerous and very interesting. A number of them are published herewith:

S. A. E. Formula Under-rates Motors—Dunham

DETROIT, MICH.—Editor THE AUTOMOBILE:—In my estimation there is but one way to rate a motor, and that is by its actual performance at 1,000 feet piston speed and not by some formula which does not give a fair rating.

The A. L. A. M. rating of today for motors considerably underrates them. It seems to me that if we are to rate cars in connection with tax matters by a formula which will underrate them, we might as well make up a new formula which will underrate them still more.

I should think it would be better to be fair in the matter, and rate the motors according to their actual developments, and endeavor to get a reasonable tax on them.

However, it seems to me both methods are wrong. If you own a house or a piece of property, they do not rate you on how big the house is, or how many rooms you have in it, or the kind of furnace you have in it, but they rate you on the value of the house. Could anything be more fair in the way of automobile taxation than rating the cars according to the amount of money they are worth? Why should a man buying one of the low-priced cars with a big engine in it pay more taxes than the man who has been able to afford a high-priced car, with a small engine?

I understand of course, that the supposition is that the larger the car, the more wear and damage it gives to the roads, but would not the whole thing equalize up as well if based on the money value of the car?—GEO. W. DUNHAM, Chalmers Motor Co.

S. A. E. Formula Cannot Be Bettered—Lewis

MILWAUKEE, WIS.—Editor THE AUTOMOBILE:—While there have been many horsepower formulæ proposed and tried. I do not believe that the formula now accepted by the A. L. A. M. and the S. A. E. can be bettered under present conditions.

The vogue of the long-stroke motor, of course, has a new bearing on the subject, but too many of our legislators who are not thorough fail to recognize the fact that piston speed is the determining factor. All piston speed taken as standard under the above formula I do not believe that the average motor under average touring conditions would exceed its A. L. A. M. horsepower rating.

I desire to add voice to those who would retain, for the present at least, the standard of rating adopted by our foremost manufacturing and engineering bodies.—RALPH C. LEWIS, F. S. Motors Co.

No Other Formula Is Necessary—Fergusson

BUFFALO, N. Y.—Editor THE AUTOMOBILE:—I do not think that any other formula than the S. A. E. is necessary or desirable in connection with manufacturers' rating, either for catalogue purposes or for state taxes. Much misunderstanding about this rating would be cleared up if it was appreciated that this horsepower is the rating at 1,000 feet per minute piston speed of the engine under consideration. Although the better made engines can be operated to give a greater horsepower than this formula, yet I doubt if the average automobile after it has been in use for a few weeks will give more horsepower than the S. A. E. rating, due to the valves not being kept in the proper condition. A pleasure car in use on the road rarely, if ever, is called upon to develop its maximum horsepower. The average running speed is about 25 miles per hour and at this speed on good, level roads the horsepower developed by even high-powered cars is rarely over 9 or 12, and only when running through heavy roads or up steep hills is anything like the maximum power of the engine developed. We believe that it is under these conditions only that the engine is scarcely ever called upon to develop more than 75 per cent. of its maximum horsepower. It would, therefore, be wrong to tax pleasure cars according to their maximum horsepower. It would be better to have a formula that would give the average horsepower developed. For this reason, we believe that the S. A. E. formula answers all purposes.—D. FERGUSSON, Pierce-Arrow Motor Car Co.

It Is Merely a Matter of Income—Mears

CLEVELAND, O.—Editor THE AUTOMOBILE:—It appears to me that, if a state is anxious to secure a given income from motor car, the horsepower rating will have very little to do with it inasmuch as the tax from horsepower could be varied to suit any change that the manufacturers might make in their rating. If we cut our horsepower in two, it would be an easy matter for the state to double its rate per horsepower.—CHARLES W. MEARS, Winton Motor Car Co.

S. A. E. Formula Is Much Too High—Sweet

DETROIT, MICH.—Editor THE AUTOMOBILE:—While the S. A. E. formula furnishes a means for the customer to make some comparisons of the various motors, it is altogether too high for the purpose of taxation if the motor is to be taxed according to the average horsepower developed in road work.

I have made some brief tests to determine the actual amount of power developed to propel a five-passenger touring car, with two passengers in it, over the ordinary city streets and boulevards. In said test, an engine was used that according to the S. A. E. formula was rated at 32 4-10 horsepower. The test did not consider any rapid accelerations nor any hill work. We found that it only required an average of a little less than 8 horsepower to propel the car at speeds ranging from 18 to 22 miles per hour, which we consider an average speed for general road work. Therefore, the power actually required for the average level road conditions is less than 25 per cent. of the S. A. E. rating.

It seems that if the rating is to have consideration for taxation purposes, it would be more just to cut the present S. A. E. rating in two in the middle.—S. E. SWEET, Cadillac Motor Car Co.

Weight a Better Basis for Taxation—Crane

BAYONNE, N. J.—Editor THE AUTOMOBILE:—Personally I would be very sorry to see the manufacturers in this country induced as they have been on the other side to build motors of excessively small bore and long stroke by any horsepower rating system used by engineers or by the public authorities. As a matter of fact, from what we now know a rating depending entirely upon piston displacement would result in a very satisfactory engine development. I do not see that the question of rating has anything to do with the charge for licensing, which, if the license charge is fair at all, as I do not believe it is, should be based on weight as well as on horsepower.

Regarding the amount of power used on the road in cars of our manufacture, these cars develop their rated horsepower under the S. A. E. formula at 750 revolutions, corresponding to a car speed of about 28 miles an hour with our standard rear axle gear ratio. All of us who have driven cars know that in this country an average speed of 28 miles an hour for a trip of any length is very high. As a matter of fact, under full throttle at 28 miles an hour our cars will hold their speed on a grade of at least 8 per cent. It is my opinion without having made any actual tests that the average horsepower delivered by the motor on ordinarily good roads is not over 25 or 30 maintaining a 28-mile average, and considerably less in maintaining a 20-mile average.—H. M. Crane, Crane Motor Car Co.

S. A. E. Formula Is Not Consistent—Lee

Detroit, Mich.—Editor The Automobile:—The horsepower rating of our motor is entirely due to the attitude of the buying public, who have been educated up to the prevalent practice of over-rating, which results from competitors endeavoring to utilize every possible selling point, any departure from which would be detrimental to the company.

The Briggs-Detroiter Co. stands ready to adopt any practical formula which will give a reasonable horsepower rating. However we do not consider the present S. A. E. formula as being consistent. Inasmuch as any motor whose dimensions are 3 3-8 by 3 3-8 will give the same results as one whose bore and stroke respectively are 3 3-8 by 5 inches.

It is safe to say that all automobile manufacturers would welcome any standard formula which would be approximately correct. If it were possible for all of them to come together in a meeting with their chief engineers, then there would be no doubt but what a thoroughly practical as well as simple mathematical computation could be formulated.—W. S. Lee, Briggs-Detroiter Co.

Stroke Should Be Considered—Stutz

Indianapolis, Ind.—Editor The Automobile:—I am of the opinion that the A. L. A. M. rating is no doubt somewhere near correct. Of course, there are some injustices in this rating owing to the proven fact that stroke does cut some figure with the amount of horsepower the motor is competent of delivering, but I am quite positive that the rated horsepower of a motor and a car as well should not be based on the maximum horsepower which it is possible to obtain, under the best possible condition, as the automobile does not remain in this condition when in the hands of the ordinary user only momentarily as the valves soon need attention, valve clearance is altered, carbon fixed and other instances happen which render the maximum horsepower rating absolutely worthless. The proportioned horsepower of the A. L. A. M. rating according to size of motor seems to be somewhere near correct, but the writer is of the opinion that stroke should be reckoned with in some cases.—H. C. Stutz, Idieal Motor Car Co.

Volumetric Displacement Important—Averell

New York, N. Y.—Editor The Automobile:—The horsepower rating should be determined by the volumetric displacement and not upon the bore alone. I think this is both equitable and will lead to better motor proportions. I also believe that the taxation should be based on a combination of horsepower and weight. I know this sounds slightly complicated and may be rather difficult to work out, but the most destructive elements to the roads are certainly horsepower, which means available sustained speed and weight.—S. G. Averell, American Locomotive Co.

Standardization Is Needed—Reed

Martinsburg, W. Va.—Editor The Automobile:—I believe that many makers can obtain surprising results in the way of power from our motors. We cannot make the statement that 75 per cent. or even 50 per cent. of this is delivered at the point of contact of the rear wheels and the ground.

Taking the average six-cylinder touring car, which we will assume has a piston displacement of approximately 375 to 400 cubic inches and rated by the makers at 60 horsepower, more than that which the motor itself will develop on the block.

This car running at a speed within the reguations set down by law of 20 to 25 miles per hour in the country, is requiring but approximately 18 to 20 horsepower to drive it, and with the efficiency of power transmitting and speed-reducing machinery that has been reached today, 25 to 30 horsepower is the maximum you can credit to the motor, as it would probably be turning about 700 revolutions per minute.

The rating of gasoline motors for automobiles has become so complex that the layman has really no way of telling that a certain motor rated at 30 horsepower can out-pull two motors in cars of another make rated at 40 horsepower; and there should certainly be some standardization of this among the many other lesser matters which are brought to certain classifications.—W. S. Reed, Norwalk Motor Car Co.

More Actual Horsepower—Potter

East Orange, N. J.—Editor The Automobile:—In any logical rating, such as the S. A. E. or one considering stroke, weight, price or size, is absolutely fair to all concerned. The necessary raise in taxation in order to keep the highways in good condition, together with the necessary or unnecessary increase in the price of gasoline makes it important that the American engineer should study and consider more thoroughly the absolute necessity of building a motor that will develop more actual horsepower.

Not only do the racing results of foreign countries, but also the stock road endurance runs show that the foreign engineer is getting more horsepower with less fuel consumption. A recent test made by the Automobile Club of America on one of the leading automobile manufacturer's motors showed anything but a satisfactory and economical result. The gasoline consumption as given by the average automobile salesman compares favorably with that actually obtained by owners of foreign machines, but the actual speed in miles per hour obtained by the American car owner falls short of that claimed by the salesman by 6 to 9 miles per hour.

I believe that the race on Decoration Day at Indianapolis will prove conclusively to the American engineer that he must consider more carefully the weight of moving parts, compression, valve diameters and lift, cam design, size, dual length of the intake manifold.—M. H. Potter, Junior Member, Society of Automobile Engineers.

Surplus Power Tax Is Unfair—Batenburg

Clintonville, Wis.—Editor The Automobile:—In actual operation on highways, and especially in towns where the speed is limited, the amount of horsepower produced is far below the S. A. E. or A. L. A. M. rating.

The amount of power not produced to the wheels will depend more or less on the entire construction of the car, and the weight and type of body and character of load.

In my opinion the A. L. A. M. or S. A. E. rating is more than high enough on touring cars as well as trucks. Of course, in truck service the amount of horsepower produced will occasionally show higher than the above rating, especially by overloading, but, on the other hand, bear in mind the number of times that the car runs empty or with light load, and at low speed, and in such cases the power produced is way below the A. L. A. M. or S. A. E. rating. All automobile designers of today are figuring on sale overload and also to take care of a large amount of reserve power.

It is only a question of whether the secretary of state will give us credit for the amount of horsepower that is used under average conditions, which we would judge is full power only 25 per cent. of the time during the entire year. If we are charged up with surplus power during the idle period it would be unfair. —P. Batenburg, Four-Wheel Drive Auto Co.

Accessories for the Automobilist

A. PETERSON, of the service department of the Garford company, New York City, has designed a valve spring compressor by means of which it is possible to raise the valve spring in 10 seconds and have both hands free when the spring is in that position to remove the key. The method of operation of this simple instrument and the principle upon which it operates may be seen in Fig. 1. The compressor consists of four parts:

1—A curved bar A, having a fork at its lower extremity. The fork slips beneath the lower spring support.

2—A right-angle bell-crank lever B. This operates in a clevis at the top of the curved bar and does the lifting.

3—A pin C, suspended from the bell-crank which fits into the center of the valve head and takes the thrust occasioned by compressing the spring.

4—A shoulder piece D, located on the pin. This fits into the valve aperture at the top of the cylinder and centers the pin so that it strikes the hole in the center of the valve head.

The operation will no doubt be clear from the foregoing description of the parts. The operator merely slips the lower end of the forked bar A under the spring seat at the bottom of the valve and the pin C down through the opening above the valve. The shoulder D will come over the opening in the cylinder caused by removing the valve cover. The bell-crank lever is moved from the position it occupies in the left view of Fig. 1 to the position shown at the right. This will cause the spring seat to be lifted up and will leave the pin free to be removed.

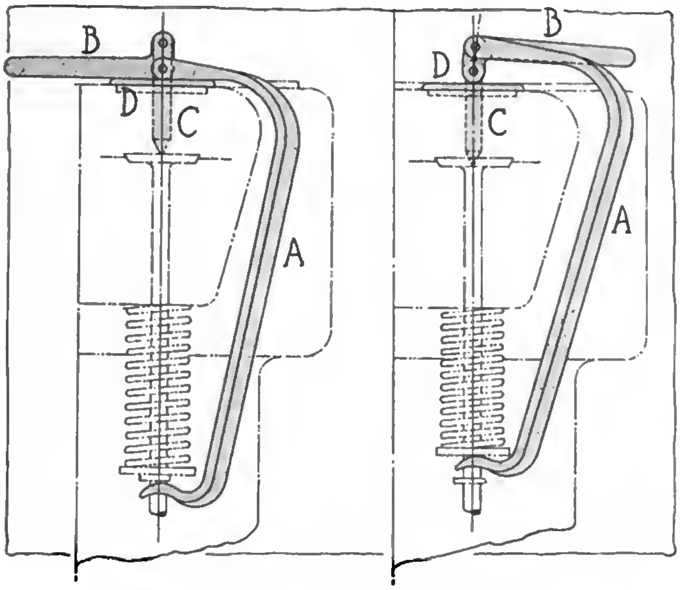

Fig. 1—Peterson valve spring compressor

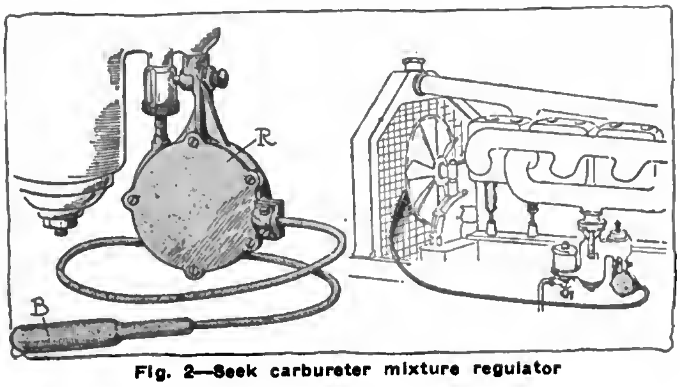

Fig. 2—Seek carbureter mixture regulator

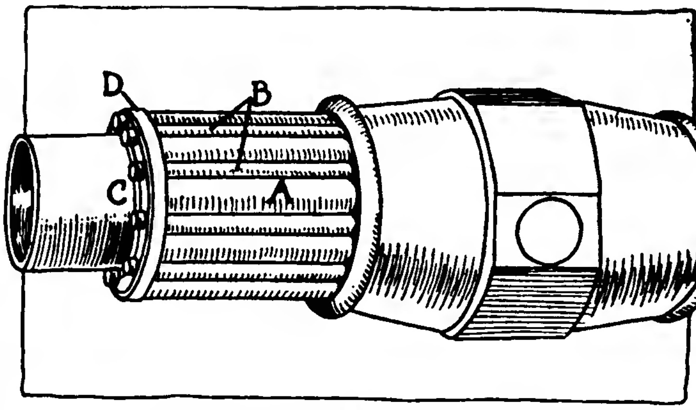

Fig. 3—American greaseless roller bearing

Owing to the fact that the bell-crank lever is slightly over the center position, the upward thrust tends to press the handle of the bell-crank more tightly against the top of the forked bar. In other words, it has no tendency to release the valve regardless of the amount of thrust.

The J. R. Almond Mfg. Co., Ashburnham, Mass., makes the flexible casing, Fig. 6, which is composed of a double-wound wire tube. The inner wire is of tempered spring steel and has a flat surface coiled toward the inside to support the flexible shaft; the outer wire coil provided to make the casing oiltight is of solid brass wire, rustproof, and has the appearance seen at the ends of the two sample pieces shown in the illustration.

Seek Regulator—A carbureter attachment designed to automatically regulate the mixture according to variation in the temperature of the water cooling system of the motor has recently been introduced by the Seek Regulator Co., Chicago. Fig. 2 shows the device A and the method of applying to motor. The Seek regulator may be attached to any make of carbureter without removing the carbureter from the car. Its operation depends on either the control of the air valve or the gasoline needle, according to choice or the particular make of carbureter. A flexible tube extends from the regulator itself to a bulb B, containing mercury, set against the motor side of the radiator and securely fastended there. The same result will be obtained if the bulb is applied within the water jacket, but it is preferably attached to the radiator so as to be sensitive to the temperature of the tubes and also to be influenced by air drafts. Whatever may be the temperature surrounding the bulb it influences the mercury in the bulb and immediately proportions the mixture, operating accurately within 1 degree indicated temperature and having a range of .3 inch of valve movement. When attached the carbureter is adjusted under normal weather conditions as nearly correct as possible, the regulator is then set in position to have no effect at this temperature, beginning to act only when the temperature of the water jacket falls below 180 degrees. It will then automatically care for the mixture. If a motor has been permitted to stand for some time in the cold this regulator will automatically give it a rich mixture at the start, and by degrees in accordance with the rise in the temperature will permit the mixture to weaken so that as soon as the motor has warmed to a temperature of 180 degrees it is running under normal conditions.

An anti-friction roller bearing requiring no lubricant has been designed by the American Roller Bearing Co., Pittsburgh, Pa., who claim to have tested it out on a 30,000-mile run. The construction is seen in Fig. 3, where alternate large rollers A carry the load, while smaller rollers B grooved at their ends act as separators, running in tracks C. Retaining rings D, which are freely movable, hold B in place. By this construction only rolling contact is obtained and all sliding friction is avoided.

The Elgin Spark-Plug & Ignition Co., Elgin, Ill., manufactures the spark-plug, Fig. 7. This plug consists of a steel shell, a steel bushing and a porcelain, which latter is separated from the shell by a copper ring and by an asbestos washer. The most interesting features of this plug are the specially designed porcelain and the electrode. The former is seen in Fig. 7, where the shell is cut away at one point. The shape of the porcelain is such as to form a primary ignition chamber above the lower, diverging end of the porcelain, and the upper edge of this chamber is formed by the asbestos washer, which is pressed tight against the insulation by the very explosion pressure. The electrode is of wire bent in a right angle toward the shell, a metal cap forming a shield over it against the porcelain and preventing leakage of gas through the passage containing the wire.

An automatic carbureter, designed by the engineer Edouard Cannevel of Levallois, France, is shown in Fig. 9. The principle utilized in this carbureter is the breaking up of a liquid by means of a fixed orifice which is called a compensator in relation to the velocity of air passing through the carbureter. The design here illustrated not only has the ability of impoverishing the mixture in proportion with the decreasing suction, but it also permits of complete supression of the carburetion of air, when the motor reaches a certain velocity at which the suction created by it, the velocity of the air drawn in and the difference of fall between the two fuel orifices are at equilibrium. Coming to a description of the mechanism itself, the latter is of the float-feed type, the level of the fuel being a millimeter or two above that of the gasoline nozzle. The latter has three orifices, the top one being that which serves for principal action, while the two lower ones which are on one level permit of fuel leaving the inner lead and being diffused around the upper orifice, thereby breaking up the principal or, rather, the single jet. The canal into which the two lower orifices discharge before reaching the level of the upper orifice form a storage space in which fuel is kept for the purpose of starting, being available at the first bit of suction of the motor. In operation, the upper jet is the only one used at low speeds, when the motor suction is relatively small. When, however, the motor is accelerated by the opening of the throttle, the gasoline stored in the channel surrounding the lowest portion of the lead bored through the body of the nozzle is sucked up and mixed with the fuel discharged through the main orifice, thereby enriching the mixture. In order to protect the lower orifices against too great a suction, a disk is placed above them around the nozzle body, providing at the same time a larger surface for the fuel to cling to, which also facilitates evaporation.

The Ohio Top hoist, Figs. 4 and 5, is being made by the Ohio Top & Mfg. Co., Toledo, O., for the purpose of making it easy for one person to operate the automobile top. It consists simply of two long rods which attach to the points where the front and the rear uprights of the automobile top are united. As Fig. 4 shows, each rod consists of two sections, one of which is fastened to each of the points mentioned, they being held together by a screw-thread. The device is used in the following manner. If it is desired to put up the top, the driver attaches the rear sections, slips the front sections through the eyelet ordinarily used for attaching the front supports and then screws the sections together, which form a rod for the front support connection to slide upon.

The Johnson Steel Works Corp., Boston, Mass., manufactures the steel wheel illustrated in Fig. 8. The latter is built heavily of cast crucible steel alloyed with vanadium and titanium, and specially heat-treated. As a result the steel is tough, strong, ductile and well capable of resisting shocks. It is also made of acid-open-hearth steel, but the intention of the company is to use in the future only electrically-made steel and alloy steels of the above description. A tensile strength of 75,000 to 80,000 is thereby obtained, which is much in excess of the strength of any wooden wheel. The weight of such a steel wheel is of course greater than that of a wooden one, but to make up for that it is applicable to a wider field, being capable of carrying loads too great for wooden wheels. As Fig. 8 shows, the wheel is made both single and dual, with eight or ten spokes respectively. These wheels are shod with steel tires to give good service and seem to be recommendable, especially in the case of heavy trucks and omnibuses.

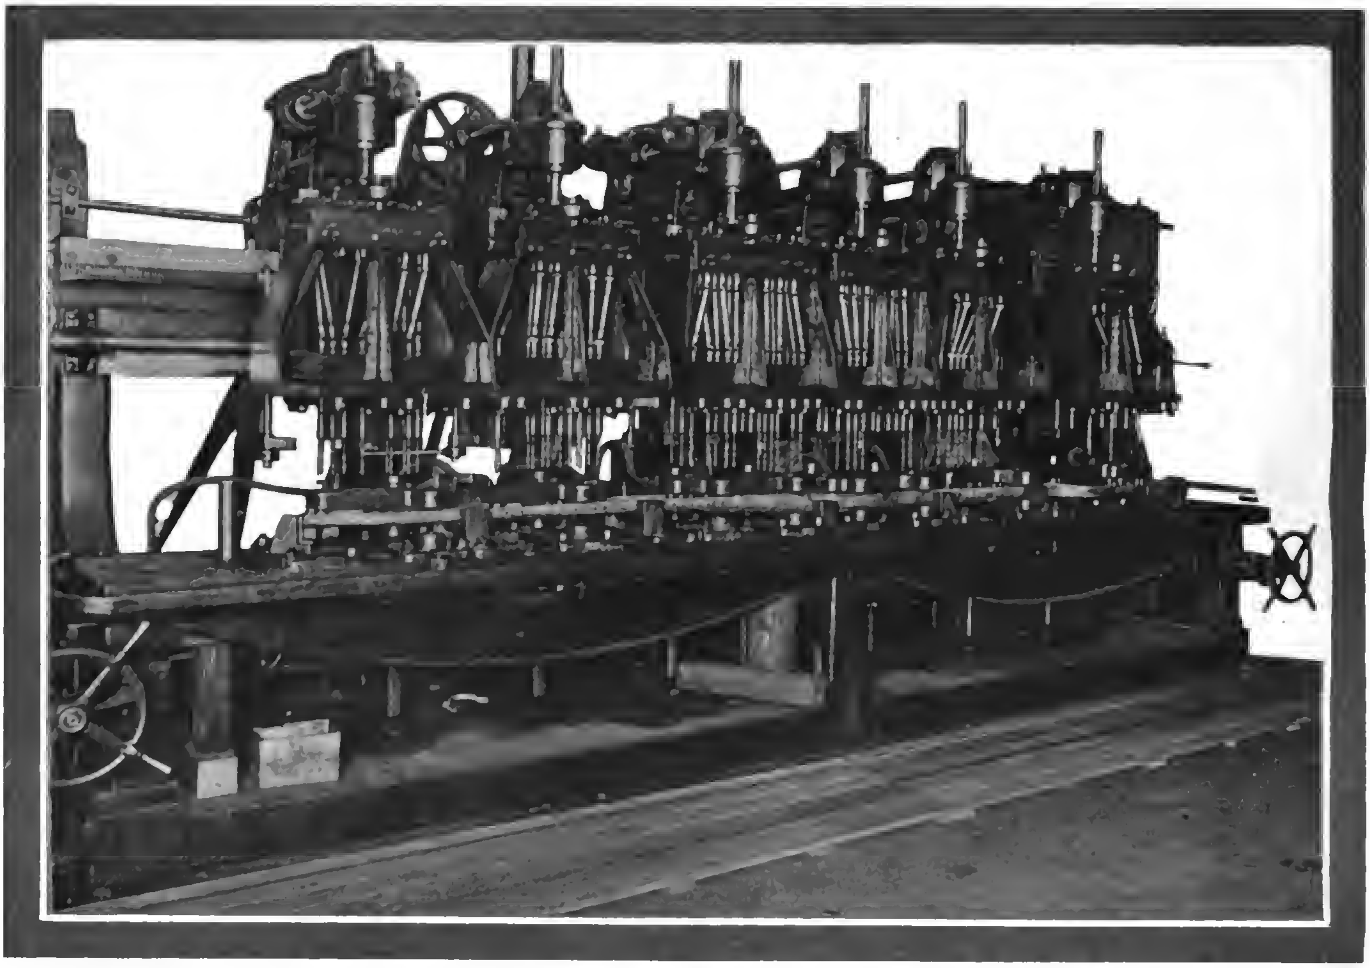
Factory Miscellany



Cadillac multiple spindle gang drill for frame side members. It drills seventy-two holes in 30 seconds

AUTOMOBILE manufacturing work calls for many drilling operations. This is especially true of the frame members which have to take the connections binding the frame together besides all the members of the car itself, which are carried and supported by the frame. The multiple spindle drill in the above illustration is said to be the largest in the world used in connection with the automobile industry. It is installed in the factory of the Cadillac Motor Car Co., of Detroit, Mich., and is used exclusively for drilling the holes in the side bars of the frame. The machine is capable of drilling seventy-two holes at one operation. Two men working on this machine will drill all the holes in a frame side bar in about 30 seconds. This is just thirty-six times as fast as would be accomplished by former methods—a gain of 3,600 per cent. in time. A thousand right-side frame channels are drilled at one set up and then in 2 hours the drills and jigs are changed and the machine is ready for drilling the holes in a thousand of the left-side channel bars. The machine occupies 8 by 18 feet of floor space—just a little more than would be occupied by two single-spindle frame drilling machines with their stands for supporting the bars. Including the time for shifting the stock, etc., the capacity of this machine is about 100 pairs of side bars per day.

ESTERLINE'S New Factory—The Esterline Co., Indianapolis, Ind., moved into its new factory recently. This plant has a floor space of 108,000 square feet, which is an increase of more than 100 per cent. over the former plant. The building is three stories high, of reinforced concrete construction throughout. The employees number 200 and the entire plant at its full production will be in the neighborhood of 450. This company manufactures lighting and starting systems, lamps, headlights and the Esterline graphic meter.

Universal Machinery Has Fire—The Universal Machinery Co., Milwaukee, Wis., builder of Progress motor trucks and parts, sustained a loss of $5,000 by fire recently. Several departments suspended operations for 10 days while repairs were under way.

Rubber Plant in Columbiana—The Columbiana Land Co., Columbiana, O., has purchased a tract of land in that city on which they propose to erect a rubber plant. A. E. Albright of Carrollton, O., is president of the company and D. A. McIntosh of East Palestine is vice-president.

Marathon's Addition—The Marathon Tire & Rubber Co., Cuyahoga Falls, O., is arranging to enlarge its plant to take care of increasing business. The new additions in course of erection will afford 2,200 square feet of floor space. Additions are being made in the vulcanizing and puring rooms.

M-A-Z Plant in Kenosha—H. M. Mink, Edward Anderson and J. P. Zens have formed a corporation under the style of M-A-Z Concealed Hinge Co., capital stock $10,000, to manufacture hinges and locks for motor car bodies and other purposes. A plant will be established in Kenosha, Wis., at once.

Hans Equipment's Plant—The Hans Motor Equipment Co., La Crosse, Wis., will be the first industry to occupy a share of the 64-acre tract of land purchased by the Industrial Association of La Crosse to provide free factory sites for new industries locating in that city. The tract is touched by two trunk railroads and is connected with the Mississippi River by the Black River. The company is so crowded for space that several automatic machines have been anchored on planks and covered with a large canvas tent.

Milwaukee Motor's Increased Output—The Milwaukee Motor Co., Milwaukee, Wis., manufacturing motors and unit power plants for the trade, has increased its capital stock from $250,000 to $300,000. The plant was recently enlarged so that the output is at present from 40 to 60 per cent. in excess of the production a year ago.

Lamp Factory in Indianapolis—A factory for the manufacture of motor car lamps and sundries will be established in Indianapolis, Ind., by the newly organized Auto Headlight & Oscillator Co., in which N. E. Carter, C. R. West and C. F. Gordon are interested. The company has been incorporated with an authorized capitalization of $50,000.

Enlarge Hudson Plant—The Hudson Motor Car Co. is erecting a new building at Detroit, Mich. The new structure is to be 578 feet in length by 90 feet in width and will supplant the section of the factory grounds which resembled a tented city. The latter existed because contractors would not complete buildings fast enough to take care of the output of the cars.

New Sheboygan Plant—The American Gas Engineering Co., Sheboygan, Wis., recently organized at that city with a capital of $50,000, has broken ground for a plant consisting of three buildings. The company will first engage in general machine work, cutting, welding, etc., and later intends to manufacture gas and gasoline engines. Automobile work will be featured.

Remodeling Building for S. & M. Tire—The remodeling of the old Premium building on Cambridge street, Coshocton, O., for the S. & M. Tire & Rubber Co. will begin at once The new industry, which is moving there from Akron, O., expects to be in operation within 90 days. The company expects to arrange for the erection of a steel plant for the manufacture of steel rims for tires.

John Brown's New Site—Announcement is made by the J. W. Brown Mfg. Co., Columbus, O., that a new site consisting of 5 acres on the Marion Road has been acquired and the work of constructing a modern plant will be started at once. This move was made necessary because of the large increase in the business of the concern, which manufactures automobile lamps and trimmings.

Power for Automobile Supply Factories—The Ross & Young Machine Co., which is erecting a new factory in Detroit, Mich., for building the Page automobile, is installing a 4-cylinder, 100-horsepower Bruce-Macbeth gas engine, which will supply power and light. The Willard Storage Battery Co., Cleveland, O., which a few years ago placed its fifth repeat order for these engines, recently placed another order for a 150-horsepower.

Proposed Plant at Jefferson—E. A. Woodruff of Jefferson, Wis., has had a conference in that town with W. G. Moore and C. J. Smith of Cleveland, O., with a view of interesting these gentlemen in the construction at Jefferson of an automobile factory. The company proposed to manufacture the body, but would buy wheels, tires, electrical equipment and motors outside the factory. The initial equipment will consist of a 250-horsepower gasoline engine, motors for machines, gas furnaces, hydraulic stamps, etc. A subscription of $40,000 to the company's capital stock is asked as a consideration of their coming to the city.

Wrapping room at the plant of the Goodyear Tire & Rubber Co., Akron, O. Here tires are wrapped prior to undergoing the second cure.

The Automobile Calendar

Shows, Conventions, Etc.

May 20-21.........Boston, Mass., Convention of Electric Vehicle Makers.
May 20-23.........Baltimore, Md., Spring Meeting, American Society of Mechanical Engineers.
June 2-7...........Racine, Wis., "Made in Racine Exposition," J. I. Case Co.'s foundry.
June 5, 6, 7........Detroit, Mich., Midsummer Meeting of Society of Automobile Engineers.
Aug. 28-30........Ghent, Belgium, Institute of Metals, Annual Autumn Meeting, Ghent International Exhibition.
October ....Paris, France, Automobile Show, Grand Palais; 10 days.
Oct. 13............Philadelphia, Pa., National Fire Prevention Conference, Philadelphia Fire Prevention Commission.
November ....London, Eng., Annual Automobile Exhibition, Olympia.

Race Meets, Runs, Hill Climbs, Etc.

May 14-15.........New York City, Start of 2-Day Hudson and Catskill Scenic Tour.
May 17............Atlanta, Ga., Automobile and Accessory Assn. Annual Hill Climb.
May 29-30.........Chicago, Ill., Inter-Club Reliability to Indianapolis, Ind., Chicago Motor Club vs. Illinois Athletic Club.
May 30............Indianapolis, Ind., 500-Mile Race, Speedway.
June 5.. ....New York City, Orphans' Day Picnic at Glen Island, Orphans' Automobile Day Assn.
June 7.............Philadelphia, Pa., Inter-Club Reliability, Quaker City Motor Club, Automobile Clubs of Delaware County, Philadelphia and Germantown.
June 14..........Cincinnati, O., Hill Climb, Cincinnati Auto Dealers.
June 16, 17, 18....Columbus, O., Reliability Contest, *Ohio State Journal.*
June 19............Chicago, Ill., Algonquin Hill Climb, Chicago Motor Club.
June 21............Cincinnati, O., Hill Climb, Cincinnati, O., Automobile Dealers.
June 25-28.........Chicago, Ill., Non-Motor-Stop Reliability, Chicago to Boston, Chicago Automobile Club.
July 1.............Indianapolis, Ind., Tour of Indiana Automobile Manufacturers' Assn. to the Pacific Coast.
July 1-16..........Winnipeg, Man., Motor Plow Competition, Dr. A. W. Bell, Manager.
July 4.............Columbus, O., 200-Mile Track Race, Columbus, O., Automobile Club.
July 4.............Taylor, Tex., Track Meeting, Taylor Auto Club.
July 4-5...........Sioux City, S. Dak., Track Meetings, Sioux City Automobile Club and Speedway Assn.
July 5-6...........Tacoma, Wash., Road Race, Montemara Festa Automobile Committee.
July 8-16..........Winnipeg, Man., Midsummer Exhibition, A. C. Emmett, Manager.
July 11............Twin City, Minn., National Reliability Tour, A. A. A.
July 27............Grand Rapids, Mich., Tour, Grand Rapids Auto Club.
July 27-28.........Tacoma, Wash., Tacoma Road Races.
August 5..........Kansas City, Mo., Sociability and Endurance Run from Kansas City to Colorado Springs, Col., Kansas State Automobile Assn.
Aug. 12...........Kansas City, Mo., Reliability Tour, Kansas State Auto Assn.
Aug. 29-30........Elgin, Ill., Elgin Road Races, Elgin Road Race Assn.
Aug. 30-Sept. 6....Chicago, Ill., Reliability Run, Chicago Motor Club.
Sept. 1............Columbus, O., 200-Mile Track Race, Columbus Auto Club.
Sept. 9............Corona, Cal., Track Race, Corona Auto Assn.
Oct. 4-11..........Chicago, Ill., Around Lake Michigan Run, Chicago Motor Co.
Nov. 24...........Savannah, Ga., Vanderbilt Cup Race, Motor Cups, Holding Company.
Nov. 27...........Savannah, Ga., Grand Prize Race, Automobile Club of America.

Foreign.

May ....St. Petersburg, Russia, International Automobile Exposition, Building of Michael Maneze, Imperial Automobile Club of Russia.
June 3-7..........London, Eng., Third International Road Congress, Rees Jeffrey, General Honorary Secretary.
June 23-28........London, England, International Road Congress.
July 12............Amiens, France, Grand Prix Race.
July 13............Paris, France, French Grand Prix Cyclecar Race.
July 18-26......... London, Eng., Imperial Motor Transport Conference.
Sept. 21...........Boulogne, France, 3-Litre Race.
Sept. 25...........Isle of Man, International Stock Car Race.
October ....Paris, France, Paris Automobile Show.

The Week in the Industry

Engineer — Dealer — Repairman — Garage

Six of the seventeen remaining Shakers of Union Village, near Lebanon, O., start out for a short run in their six-cylinder Pierce

Reo car converted into a motor lawn mower by the Quincy Country Club, Quincy, Ill. This car was a 1907 model. The mower cuts the grass in less than one-sixth the time and at less than one-fifth the cost at which it was formerly done. The 1,100 acres of ground on this golf course are cut at a cost of less than 35 cents per acre. The two-passenger body and rear system of this runabout are retained intact, while the front is supported by a triple-armed frame which converges down to the axle running through an iron roller 2 feet in diameter and 3 feet long across the chassis frame. A 3-foot mower is attached in front of this roller and another at the left side of the car. These two mowers cut a swath 6 feet wide, which, at the nominal speed of 6 miles per hour, would mean 11 acres per day of 8 hours. Assuming that the cost of gasoline is 20 cents and oil 50 cents per gallon, and the driver is paid $3 per day, the cost per acre would be less than 35 cents. A few Reo cars, as far back as 1905, have been converted into power plants for a hay-blower, corn sheller, farm tractor, threshing machine, hoisting apparatus, delivery truck or a score or more of other mechanically interesting contrivances

AGED ENJOY AUTOMOBILE COMFORTS—That the seventeen remaining Shakers of Union Village, near Lebanon, O., intend to enjoy the rest of their lives to the utmost may be gleaned from the above illustration. These seventeen survivors recently sold a part of their vast farm, receiving quite a tidy sum from the sale. As the oldest among them is 82 and the youngest is 51, it is evident that none will die in want and they have set out to enjoy the remaining years of their lives mid luxury and pleasure. Several automobiles have been purchased, among them being a Pierce, shown above. Nearly all the women, as well as the men can drive the cars.

HEADLEE LOS ANGELES MANAGER—F. M. Headlee has succeeded A. C. Luby as manager of the Chalmers-Los Angeles, Cal., Co.

AKRON FIRM DOUBLES CAPACITY—The Akron Tire Co., Philadelphia, Pa. has doubled its capacity by absorbing the adjoining property, the two structures having been reconstructed into one building.

HOLZWORTH STEWART SALES MANAGER—George Holzworth has been appointed sales manager of the E. Stewart Automobile Co., Northern California distributer of the S. G. V. car in San Francisco.

DASEY HARTFORD SUSPENSION MANAGER—P. J. Dasey has been made manager of the Detroit, Mich., branch of the Hartford Suspension Co., Jersey City, N. J. His headquarters will be at 803 Woodward Ave.

BOSCH SERVICE STATION IN SPOKANE—The Bosch Magneto Co., New York City, has established a service station for the Inland Empire in Spokane, Wash., having arranged with the Spokane Cycle & Supply Co., to maintain this service.

McDUFFEE STEARNS FRISCO MANAGER—J. H. McDuffee has been appointed manager of the San Francisco, Cal., branch of the F. B. Stearns Co., Cleveland, O. He succeeds J. F. Toole, who goes to Atlanta, Ga., to take charge of the Stearns interests in the South.

GOUDIE WITH PENNSYLVANIA TIRE—J. Q. Goudie, for some time past the manager of the Detroit, Mich., branch for the Diamond Rubber Co., Akron, O., has become associated with the Pennsylvania Rubber Co., Jeannette, Pa., in charge of Michigan and Ohio, with headquarters at Detroit.

PHILADELPHIA FIRM BANKRUPT—Creditors of the Sweeney Automobile Co., Philadelphia, Pa., have filed a petition to have that concern adjudged an involuntary bankrupt. The creditors and the amounts of the claims are: H. F. Hare, $750; T. F. Brennan, $266, and August Friend, $520.

CLEARING HOUSE IN LOUISVILLE—The Automobile Clearing House Co. of Louisville, Ky., has opened up offices and salesrooms at 708 Fourth avenue for the purpose of buying and selling second-hand and rebuilt cars. The managers of the new firm are W. J. Welsh and C. L. Holden.

GASOLINE WAR IN CALIFORNIA—A gasoline war is on in Southern California and as a result some of the dealers have cut prices to as low as 14 cents a gallon. How long this generous price will continue has not been determined, but it is declared that heavy losses will be sustained if the war does not end soon.

CLEARING HOUSE WANTED IN HARTFORD—A movement is on foot in Hartford, Conn., for the organization of a dealers' second-hand car clearing house. Many of the dealers are overburdened with second-hand vehicles at this time and in one or two instances a crisis is being faced. At the beginning of the season it was understood that no old cars would be taken in exchange for new, but the scheme fell flat. Competition is very keen. Now the dealers realize that the situation is becoming alarming.

COLE PARISH FACTORY MANAGER—The Parish Mfg. Co., Detroit, Mich., has engaged S. J. Cole as factory manager.

BURKE BUICK CLEVELAND MANAGER—D. A. Burke is the new manager of the Cleveland, O., branch of the Buick Motor Co., Flint, Mich.

KIRCHER MANAGER PACIFIC COMPANY—C. F. Kircher has been named manager of the truck department of the Pacific Car Co., Seattle, Wash.

BROOKLYN ORPHANS' DAY OUTING—The Orphans' Day Outing held by the Long Island Automobile Club, Brooklyn, N. Y., will take place on June 3 next.

SELLS SECOND-HAND CARS—The York Auto Exchange, York, Pa., has opened a garage at 26 North Duke street for the sale of second-hand cars and accessories.

LOUISVILLE CLUB QUARTERS MOVED—The quarters of the Louisville, Ky., Automobile Club have been moved from the Hotel Henry Watterson to the Inter-Southern building.

HARSH WITH SANDUSKY AUTO PARTS—W. H. Harsh has been made assistant general manager and assistant treasurer of the Sandusky Auto Parts & Motor Truck Co., Sandusky, O.

REYNOLDS WITH CHAMPION COMPANY—E. H. Reynolds, Jr., formerly connected with the selling of Warren cars, has gone to the Champion Ignition Co., Flint, Mich., as an Eastern representative.

REO'S LOUISVILLE QUARTERS MOVED—The Clark Motor Car Co., agent for the Premier and Reo cars, has moved its offices and salesroom from Green street to the new building at 206 East Broadway.

CHICAGO SAINT LOUIS TIRE BRANCH—The Saint Louis Tire & Rubber Co., St. Louis, Mo., recently opened a branch in Chicago, Ill., at 2027 Michigan avenue. Mr. Alexander Hendel is in charge.

NEW VELIE FORCE—A. W. Bartlett has been made general manager of the recently incorporated Velie Motor Car Co., St. Louis, Mo. W. J. Carter and C. F. Swartz are also connected with the company.

HOPKINS RESIGNS FROM ALCO—N. S. Hopkins has resigned his position with the American Locomotive Co., Providence, R. I., where he had charge of the main manufacturing department for the past year.

LOZIER'S OFFICES CHANGED—The Louisville, Ky., Lozier Co., agent for the Lozier, Paige and Palmer-Singer, has changed its offices and salesroom from Seventh street and Broadway to 405 West Broadway.

FRENCH DISTRIBUTOR FOR MOTOMETER—Y. D. Rose, of 34 Rue Du Mont-Thaber, Paris, France, has been appointed the sole distributor for France of Boyce Motometers. Mr. Rose will make his headquarters in Paris.

FIFTY-SIX AUTOMOBILES DESTROYED—Fifty-six electric automobiles were burned recently in a fire that destroyed a garage and storage warehouse in East Forty-seventh avenue, Chicago, Ill., the loss amounting to $250,000.

MORRIS GETS GOODYEAR MANAGERSHIP—M. E. Morris has been appointed Pacific Coast manager for the Goodyear Tire & Rubber Co., Akron, O., succeeding W. T. Powell, who has resigned. F. E. Carroll remains manager of the local branch in San Francisco, Cal.

LOZIER FACTORY BRANCH IN SEATTLE—The Lozier Motor Co., Detroit, Mich., will put a factory branch in Seattle, Wash. Carl Schnorr has arrived to take charge of the mechanical end of the business. The Lozier branch will have headquarters in the Motor Bldg.

NEW FRISCO HOME—The new home of the United Motors Co., San Francisco, Cal., located at Van Ness avenue and Cedar street, will contain 17,600 square feet of floor space. The showroom will cover an area of 40 by 70 feet and will be finished in pearl white.

TWO-MILE TRACK IN SEATTLE—H. W. Doherty has interested a large number of Seattle, Wash., dealers and motorists in the project to build a two-mile brick or cement track adjacent to that city. Actively associated with Mr. Doherty in the proposed track is D. G. Van Brunt.

DOVE WITH HAVERS—H. E. Dove, who has been acting in the capacity of branch manager for the Buick Motor Co., Cleveland, O., has become associated with the Havers Motor Car Co., of Port Huron, Mich., in the capacity of Pacific Coast manager for that company. His headquarters will be at San Francisco, Cal.

GOODYEAR BRANCH'S NEW STRUCTURE—The Louisville, Ky., branch of the Goodyear Tire & Rubber Co., Akron, O., is now located at 331 East Broadway. The new structure is equipped after the general scheme of all Goodyear branches in the country. Two stories and a basement are occupied by the branch, there being about $150,000 worth of stock in the building.

N. Y. PULLMAN ALTERING QUARTERS—The Stewart Automobile Co., New York City, handling the Pullman car, has been compelled, owing to business enlargement, to make a number of alterations in its building, 231 West 54th street. The entire ground floor has been turned over to the sales force. The upper floors will be devoted to academic purposes and the service department.

CHANGES IN AMERICAN MOTORS—A number of important changes are announced by the American Motors Co., Indianapolis, Ind., in its sales organization. D. B. Williams, advertising and publicity manager, has resigned that position to take a position in the sales organization as district sales manager, with headquarters at Louisville, Ky., covering a number of the Southern states and devoting his whole time to the dealers handling the American cars and the development of that territory. G. L. Moskovics, formerly assistant advertising manager under Mr. Williams takes the place made vacant by him. E. H. Sherwood has been appointed assistant sales manager.

INTERNATIONAL MOTOR COMPANY CHANGES—Recent changes in the motor truck field are announced by the International Motor Co., New York City; Ambrose Monell succeeds Edmund C. Converse as chairman of the board of directors; W. C. Dickerman retires from the position of chairman of the executive committee, leaving its duties temporarily to first vice-president John Calder. E. C. Fink, lately assistant to the president, has been elected third vice-president. D. C. Fenner resigns as New York sales manager to accept special duties in the general sales organization, and is succeeded by Kenneth M. Blake, who adds to his sales duties those of branch manager. R. E. Fulton becomes chief sales manager and R. G. Randolph is appointed New York service manager.

Alco car with 145,000 miles record which will compete in Chicago-Boston non-stop reliability contest June 25-29

One day's shipment of ten Reo roadsters to the American Radiator Co., New York City, for use by their travelling salesmen

WAVERLEY ELECTRIC MOVES—The Waverley Electric Co., New York City, has moved into new quarters at 1922 Broadway.

ANGLADA'S NEW OFFICES—J. A. Anglada has moved into new quarters at 1790 Broadway, in the United States Rubber Bldg., New York City.

NEW CONCERN IN DALLAS—A new firm has opened in Dallas, Tex., by the name of Knight & Mitchell. This concern will be dealers for the Liquid Tire Tonic and will be distributors for the entire state.

SACKS GRAY & DAVIS MANAGER—C. O. Sacks, president and treasurer of the Rowland Advertising Agency of New York, has accepted the position of advertising manager for Gray & Davis, of Boston, Mass. He will take up his new duties about July 1, with headquarters at the plant.

MOTOR TRANSPORT IN CEYLON—The Governor of Ceylon has agreed to receive a deputation from the Ceylon Planters Assn. and the Colombo Chamber of Commerce regarding the need of introducing motor transport services in the Colony and of making the roads suitable for this purpose.

UNIQUE GUIDE BOOK ISSUED—A unique guide book is being issued by the Kansas Automobile Assn., Kansas City, Mo., giving the leading roads between all the towns of the state as well as the ten leading trans-continental routes. It is being distributed free to the members of the association. It will not be sold to anybody.

HAYNES INCREASES STAFF—The Haynes Automobile Co., Kokomo, Ind., has appointed Robert Crawford as advertising and publicity manager and L. E. McKenzie as assistant in the sales department. The state of Kentucky has been assigned to F. C. Headington, who will act as field representative there.

TURNS LIGHT ON TAXI TAXI CONDITIONS—F. Ducasse who has been in the taxicab and taximeter business for many years has submitted to the special committee of the New York City Board of Aldermen a statement on the taxicab situation in the city. An array of facts is set forth by Mr. Ducasse to prove the undesirability of abolishing private stands and of decreasing taxicab rates.

SHERIDAN BUS LINE ORGANIZED—The Sheridan Motor Bus Co., Sheridan, Ind., has been organized to conduct a motor bus business, carrying passengers and light freight between Sheridan and Noblesville. The line will also work in conjunction with the Union Traction Co., of Indiana, connecting with the electric interurban line at Noblesville. Two motor buses with a capacity of twenty passengers each will be used.

SYRACUSE DISTRIBUTOR MOVES—E. P. Young, distributor for central New York of the Regal and Maxwell cars, has moved into his new quarters at 212 Jackson street, Syracuse, N. Y. It is a new two-story building of concrete and steel, the front of pressed brick and cut stone. The ground floor will contain the office, salesroom and the garage proper. The second floor will have the service station and repair shop and there is a hydraulic elevator.

Recent Incorporations in the Automobile Field

AUTOMOBILES AND PARTS

ATHENS, O.—City Automobile Co.; capital, $12,000; to deal in automobiles. Incorporators: Ura Butcher, Dana Connett, G. H. Junod, C. J. Allstock, Mabel Butcher.

AUBURN, N. Y.—Ross Automobile Co., capital, $10,000; to deal in automobiles. Incorporators: E. A. Ross, Maurice E. Tuller, H. A. Barr.

BOSTON, MASS.—Chandler Motor Car Co.; capital, $30,000; to deal in automobiles. Incorporators: R. O. Hood, E. G. Cleary, M. L. Albins Vincent.

BRITTON, OKLA.—Darling Automobile Mfg. Co.; capital, $25,000; to deal in automobiles. Incorporators: C. P. Stealey, A. W. Hedge, H. O. Crum, G. E. Crawford, S. L. Shlutaffer, D. L. Sellers, W. C. Settle, H. S. Emmerson, C. L. Stealey.

CHICAGO, ILL.—Auto Sales Co. of Illinois; capital, $2,000; to deal in automobiles. Incorporators: T. J. Peden, R. C. Merrick, J. W. Yeager.

CHICAGO, ILL.—Beeler Slide Valve Motor Co.; capital, $20,000; to manufacture motors and machinery. Incorporators: T. Burleigh Beelers, M. A. Hirshl, S. B. Hirshl.

CINCINNATI, O.—Allen-Reed Tractor Co.; capital, $50,000; to manufacture and deal in tractor engines of all kinds. Incorporators: Allen Reed, L. J. Colle, H. W. Reedy, W. C. Taylor, E. B. Lamping.

CLEVELAND, O.—Woodland Garage Co.; capital, $5,000; to deal in automobiles and supplies of all kinds. Incorporators: Jake Soglovitz, A. E. Bernstein, B. J. Sawyer, Sadie Cohn, I. Nungesser.

DETROIT, MICH.—Wahl Motor Car Co.; capital, $500,000; to manufacture motor trucks. Incorporators: G. H. Wahl, J. E. Hofweber, A. J. Hofweber, M. Kratchwill.

FALL RIVER, MASS.—Fall River Automobile Co.; capital, $10,000; to deal in automobiles. Incorporators: A. H. Harrington, P. M. Leavitt, B. A. Levy.

JACKSONVILLE, FLA.—S. & B. Motor Co., Inc.; capital, $10,000; to engage in the handling of automobiles, motorcycles, bicycles and vehicles. Incorporators: B. D. Spluney, Joseph Lockwood, J. S. Bertram.

JACKSONVILLE, FLA.—White Sales Co.; capital, $100,000; to deal in automobiles. Incorporators: J. R. Collins, P. D. Casidey, N. A. Collins.

KANSAS CITY, MO.—E. Landin Auto Co.; to deal in automobiles. Incorporators: M. J. Oldham, W. G. Bryant, M. S. Keuney, W. L. Gregg.

LOUISVILLE, KY.—The Automobile Clearing-House Co.; capital, $2,500; to handle automobiles and supplies. Incorporators: C. L. Holden, W. J. Welch, C. H. Welch.

MONTREAL, QUE.—The Montreal Autobus Co.; capital, $10,000,000; to manufacture automobile buses. Incorporators: H. S. Holt, U. H. Dandurand, F. L. Wanklyn, D. McDonald, J. S. Norris, Tancrede Bienvenue, D. Lorne McGibbon, Paul Gallbert, J. E. Wild.

NEOSHO, MO.—Neosho Auto Co.; capital, $3,500; to deal in automobiles. Incorporators: A. C. McGinty, J. F. Wills, S. D. DeLapp, F. S. Briggs, E. R. Rudy, O. L. Craven.

NEW YORK CITY.—Gallagher Carburetor Co.; capital, $300,000; to manufacture carburetors, engines, auto supplies. Incorporators: R. W. Gallagher, W. M. Foord, H. A. Johnston.

PEARL RIVER, N. Y.—Pearl River Auto Co.; capital, $5,000; to deal in automobiles. Incorporators: C. R. Kosel, Herman Gunther, Maria Kosel.

PORTLAND, ME.—M. B. Mank Motor Car Co.; capital, $10,000; to deal in automobiles. Incorporators: M. B. Mank, A. E. Mank, C. F. Mank.

UTICA, N. Y.—E. D. & A. F. Crouk; capital, $75,000; to deal in automobiles. Incorporators: Harry Lancaster, F. H. Doolittle, O. J. McKeown.

WASHINGTON, D. C.—Washington Motor Car Co.; capital, $300,000; to manufacture automobiles. Incorporators: A. Gary Carter, Frank L. Carter.

GARAGES AND ACCESSORIES

AKRON, O.—Quality Tire & Rubber Co.; capital, $1,000; to manufacture and deal in automobile tires and rubber goods. Incorporators: R. E. Smith, J. G. Guither, E. D. Smith, E. L. Smith, J. H. Robertson.

BELLEVUE, PA.—Bellevue Garage; capital, $10,000; to carry on a general garage business. Incorporators: E. A. Shaner, C. W. McCall, W. M. Barnhardt.

BUFFALO, N. Y.—Couch-Georger Tire & Mfg. Co.; capital, $10,000. Incorporators: C. A. Couch, E. F. Howell, F. P. Georger.

CHICAGO, ILL.—Federal Services Co.; capital, $2,500; to manufacture automobile supplies. Incorporators: L. O. Hack, R. S. Wertheim, S. H. Rothschild.

HAMILTON, O.—Star Taxicab Co.; capital, $5,000; to operate a taxicab and automobile service. Incorporators: G. C. Skinner, A. M. Skinner, William Miller, Merle Fenner, Millikin Shotts.

KENOSHA, WIS.—M-A-A Concealed Hinge Co.; capital, $10,000; to manufacture hinges and locks for automobile bodies and other purposes.

MIDDLETOWN, N. Y.—North End Garage Corp.; capital, $10,000; to carry on a general garage business. Incorporators: Edward Van Duser, J. G. Eager, F. F. Sheerin.

MINNEAPOLIS, MINN.—N. W. Liquid Tire Tonic Co.; capital, $50,000; to deal in automobile tires and accessories. Incorporators: F. M. Rutten, H. W. Ewing, L. P. Fay, A. G. Rose, Jr.

NEW YORK CITY.—Globe Auto Specialty Co.; capital, $4,500; to deal in automobile accessories. Incorporators: Jacob Stam, J. B. Stam, D. S. Messeson.

NEW YORK CITY.—Globe Rubber Tire Mfg. Co.; capital, $1,500,000; to manufacture automobile tires. Incorporators: H. D. James, J. P. Hall, Spencer Weart.

NEW YORK CITY.—H-H-H Tire & Mfg. Co.; capital, $50,000; to manufacture and deal in automobile tires and rubber goods. Incorporators: John Dravia, W. C. Burroughs, J. J. Coyle.

NEW YORK CITY.—J-M Shock Absorber Co.; capital, $1,000; to deal in automobile shock absorbers, etc. Incorporators: Maurice Rosvold, E. Molanchetr, Erie Aquist.

NEW YORK CITY.—Packard-Bretey Auto Renting Co.; capital, $2,500; to engage in automobile renting. Incorporators: Henry Pearlman, John Blumenthal, S. J. Loeb.

NEW YORK CITY.—Sunswick Garage and Livery Co.; capital, $2,000; to operate a garage. Incorporators: W. H. Quinn, P. J. McGlynn, T. J. O'Hanlon.

PHILADELPHIA, PA.—The New Idea Tire Co.; capital, $500,000; to manufacture automobile tires. Incorporator: F. R. Hansell.

PITTSBURGH, PA.—City Garage & Sales Co.; capital, $50,000; to carry on a garage. Incorporators: W. G. Venn, M. H. Ward, H. N. Stackpole.

PORTLAND, ME.—Berry & Winslow Garage Co.; capital, $10,000. Incorporators: Charles W. Berry, Ralph W. E. Winslow, Thomas A. Sanders.

TROY, N. Y.—Troy Auto-Bus Corp.; capital, $20,000; to operate an automobile bus line. Incorporators: John Burdick, E. L. Snydr, John McGlynn.

CHANGES OF NAME AND CAPITAL

CLEVELAND, O.—B. M. Allen Motor Sales Co.; change of name to the Velie-Paige Motor Car Co.

CLEVELAND, O.—Grant-Lees Machine Co.; change of name to the Grant-Lees Gear Co.

DETROIT, MICH.—Regal Motor Car Co.; capital increased from $1,000,000 to $3,000,000.

INDIANAPOLIS, IND.—Ideal Motor Car Co.; change of name to the Stutz Motor Car Co.

MASSILLON, O.—Croxton Motor Co.; capital decreased from $250,000 to $12,500.

The AUTOMOBILE

Spring Apparel for the Automobilist

Smart Dustcoats Mark This Year's Fashions

Fig. 1—The mackinaw is now a most popular automobile garment. Striking patterns are the rule

OBEDIENCE to the exacting dictates of Fashion is universal. It is amusing, not to say often pathetic, to realize how meekly the world submits. We all obey more or less blindly, but there are widely varying degrees of willingness manifested in the submission. And the factor which more than any other governs the readiness with which a new law of fashion is accepted is utility. We are grateful for any new rule in dress that can boast of the least suggestion of reason for the change. Too many have none; and the innate craving for something rational has to be stifled so that we can venture out into the open wrapped up in that mystery which the fashion writers delight to call *le dernier cri.*

Fashion has now to be reckoned with in the automobile. We have long passed the stage when the car itself was the thing. How to appear in it with comfort and distinction is receiving more and more consideration. A review of the automobile clothing shops reveals the fact that the satisfactory blending of appearance with utility is the keynote of this year's apparel for the automobilist. It has always seemed incumbent on the motorist to wear something different than the man in the street. In the early days he was looked on by many as a crank, and it must be confessed that if he did not intentionally dress for the part his efforts to destroy the general impression were not very noticeable. His manner of enveloping himself cocoon-like in huge and needless masses of fur was seized on with avidity by the comic artists of the period, and with good reason. Winter coats of the present time have the quality of warmth without this loud mark of external eccentricity. In this and other directions, the sartorial artist has turned his attention to the profitable field of the automobile with results that can only be looked on as satisfactory.

The general trend has been to produce garments that while supplying the peculiar needs of the automobilist do so without making the wearer conspicuous should he take to the sidewalk for a few blocks. Many of this year's overcoats, indeed, are hardly distinguishable from the ordinary overcoat. The differences lie in the direction of increased roominess, particularly at the junction of sleeve and shoulder and also about the skirt. These variations from the everyday cut are conducive to comfort in the sustained sitting posture of the motorist and hinder fatigue at the shoulder when holding the steering wheel.

Spring is now with us, the poet has had his say—or hasn't, which is just as well, and the mind of the enthusiastic motorist is dwelling longingly on the delights of touring and the open road. The time is opportune to cast an eye over the automobile wardrobe and note what deficiencies can be filled.

The most indispensable of all automobile garments is the dust coat. This year an amazing variety of types, each possessing merits worthy of consideration make it a difficult matter to form a decision when purchasing. In all of them there is a marked difference to the duster of a few years ago. At that time the owner of a car was content with something light that kept him from dust and it was thought that there were not opportunities of introducing some semblance of style into the garment. Possibly it was considered that the cheapness of the material did not warrant any expenditure of thought over the cut. A glance at the long line of dusters on view at present shows that a really smart looking garment in the various light

Fig. 2—Light raglan waterproof with velvet collar and velvet trimmed half belt. Price $25

Fig. 3—Double-breasted duster in striped gray poplin with convertible collar. Price $22.50

Fig. 4—Handsome dustcoat in light poplin with wide half belt. Listed at $25

Fig. 5—Smart duster in cravenneted worsted with breast pocket and close-fitting collar, $20.

materials that are used for this purpose can be produced at a reasonable figure. Favorite materials are mohair, linens, pongees and poplins, and there is an increasing demand for gray tones that will render the inevitable grease spots less noticeable.

The line of demarcation between the duster and the rainproof is not very definite. The rainproof proper is not so cool as the duster, but a combination garment formed by subjecting the lighter stuffs to water-proofing processes is meeting with an appreciative demand. These coats are all that is necessary to ward off the summer shower and save the trouble of changing into a rubber garment.

Many varieties of storm-resisting apparel are being displayed in the stores. The old term rainproof has been found wanting. The automobilist in a real downpour requires special protection, and any garment that can provide it is entitled to the stronger expression of being stormproof. The most perfect of these storm protectors is the so-called rubber apron much used by chauffeurs. In these, the only openings are the sleeves and a neck hole. Entry into the garment is rather a troublesome operation, but once there the elements can be defied. Besides the

Fig. 8—New driving glove with reinforced palm for hard wear

heavier types of black rubber storm apron some makers are listing a lighter type of a smarter appearance for owners.

Another form of rainproof that is popular is the white rubberized duck coat. This always remains spotlessly white and holds its shape, and trimmed with black velvet at the collar is a smart looking garment. For hot weather, however, where such a waterproof would seem uncomfortably heavy, a silk oil would better suit the purpose. These garments cannot claim anything in the way of appearance, but they are so astonishingly light, consisting practically of a transparent skin, and moreover are capable of being rolled up into such a small compass that they form a useful addition to the touring motorist's wardrobe.

With regard to the cut of the shoulder this year shows the raglan type to be still popular, although the regular inserted coat sleeve is in the majority. The collars are also divided into two camps—the tight fitting military and the conventional lapel. A type which is increasingly popular is called the convertible, and in this the lapels can be worn open during fair weather to get advantage of the breeze and folded over when protection of the throat is desired. This snug fitting of the neck is a matter that has received a great deal of attention at the hands of the designers, with the results aimed at. To prevent the entry of dust at this point goes a great way toward a tidy appearance when the garment is taken off.

Developments are also to be noted in other departments of automobile wear. Gloves, for instance, are now made with an eye on the hard usage that they are subject to on the driver's hands. Various kinds of reinforced palms are being exhibited, while the heat of a heavy driving glove is being obviated by incorporating lisle or other thin ventilating material into the backs and the unused parts of the fingers.

A glance at the displays of goggles and other face protectors shows that the main change to be noted is a demand for goggles that will be as inconspicuous as possible. There is also a great demand for large lens spectacles. These latter are being found to afford ample protection from the direct flow of dust, do not limit the angle of view as do many of the older gogle forms and furthermore permit a constant movement of air about the eye and so reduce eye strain in warm weather.

Fig. 6—Smart skeleton-lined overcoat in army cloth for the touring motorist. Price $30

Back view of army cloth coat showing half belt and center inverted pleat at the back

Fig. 7—Rubber apron that is absolutely waterproof. Snap buttons are used throughout

Showing method of fastening apron by neck bands. This storm protector is listed at $25

Not much change can be recorded in the design of uniforms for the chauffeur. What little there is in the direction of bringing the uniform more into the field of the ordinary garment.

In Fig. 1 is shown a Mackinaw jacket which is becoming exceedingly popular. These are supplied in a great variety of patterns, the one illustrated being a shepherd's plaid. They have a sporty appearance and are thick enough to afford ample protection against cold.

Fig. 2 shows a favorite type of duster in dark grey striped poplin. The collar is convertible and the garment looks smart either way. The sleeves are provided with elastic wind shields.

A cravenetted worsted double breasted duster with a high military collar is illustrated in Fig 3. This coat has a special neck tag to insure tight buttoning up of the collar, wrist shields and a pleated breast pocket, as well as the ordinary slot pockets at the sides.

The back view shows a distinctive dust coat in light poplin. A half belt of the same material extends from pocket to pocket and wrist shields in addition to outer wrist straps are fitted. The collar is high and fits the neck snugly.

Fig. 4 shows a light waterproof in dark grey with raglan shoulders. A velvet trimmed collar adds considerably to the appearance of the garment. The rubberized material is double around the shoulders. The arm holes are deep to allow freedom of movement and the arm pit is ventilated. A half belt trimmed with velvet in a similar manner to the collar is fitted behind. The side pockets are of the slot type.

Back and front views of an extremely smart overcoat for touring are shown in Fig. 6. This model, supplied in army cloth is light and is equally of use in or out of the car. The sleeves and shoulders are lined and looseness in the skirt is secured by means of an inverted center pleat extending from the waist at the back. A buttoned half belt is fitted.

Fig. 7 illustrates a storm proof apron as seen from back and front. The arrangement of the flaps at the opening for the neck are such that there is no possibility of rain entering. All buttons are of the snap pattern used in gloves. The outer collar formed in one with the breast flap is secured at the back by these buttons as shown in the back view. A strap at the wrist produces a tight fit and prevents the entry of water at that point.

An ingenious method of increasing the wearing qualities of gloves used by drivers is illustrated in Fig 8. Extra thicknesses of leather are sewn on the inner surfaces of the fingers and over the palm where the glove is in constant contact with the driving wheel. Another development in glove design is shown in Fig. 9. This is intended for summer wear when the ordinary glove is generally found to heat the hand too much. The back of the hand portion and the fingers are cut away and silk lisle of a color to match the glove inserted. By this means ventilation is secured.

The Automobile is indebted to Saks & Co., of New York, for the use of the garment shown in Fig. 1; to The Auto Supply Co., New York, for those illustrated in Figs. 5, 6, 7, 8 and 9, and to James McCreery & Co., New York, for the coats shown in Figs. 2, 3 and 4. Photographs by N. Lazarnick, New York.

Ford To Add 500,000 Square Feet

Chalmers Adds 50,000 Square Feet — Schaefer is Abbott President

DETROIT, MICH., May 20—Although it has been common property for some time that the Ford Motor Co. was contemplating the further enlargement of its plant in Highland Park. According to a statement emanating from the general offices of the Ford company the additions will increase the total floor space from 1,270,062 square feet to 1,794,974 square feet, or about 500,000 square feet. Two new factory buildings, each six stories in height and measuring 60 feet in width by 900 feet in length, are to be erected, the plans being prepared under the supervision of the company's consulting engineers.

Craneways, which will be under a glass roof, will extend the length of the structures and will afford means of transfer of parts or other material from any point in the factory to any other. The additions will mean much to Detroit, as they will make necessary the employment of several thousand more men, which will probably swell the total number to around 16,000. There are at present about 14,500 employed by the concern.

In addition to the extensions of the plant proper, two stories are to be built onto the office and administration building in front of the plant, and material extensions to the Ford sales and service station, located at the corner of Woodward avenue and Grand Boulevard, are also planned. Five stories more are to be added to the latter, while its frontage on Woodward avenue is to be increased from 100 to 321 feet. The depth of this building is 97 feet.

Chalmers' Factory Addition Planned

DETROIT, MICH., May 19—The large Chalmers Motor Co. plant on Jefferson avenue is to be further enlarged by the addition of another wing measuring 220 feet in length and 60 feet wide. The added floor space will be about 50,000 square feet, the structure being four stories in height according to the plans. The new building will be made of concrete and steel, and the ceilings will be flush. That is, there will be no exposed beams. Inclosed bridges of steel will connect each floor with those of the adjoining building. With the completion of this latest addition the Chalmers company will have added some 200,000 square feet of floor space to its already large plant within the last year, and it will bring the total expenditures for additions and improvements to plant during that period to $400,000. Five other structures have been added, ranging from one to four stories in height as well as extensions to other departments.

Schaefer Elected Abbott President

DETROIT, MICH., May 21—*Special Telegram*—The creditors' committee of three, consisting of A. H. Zimmerman, Continental Motor Mfg. Co., A. W. Lewis, Timken-Detroit Axle Co., and H. J. Mallory, Weston Mott Co., has chosen A. E. Schaefer, formerly with the Ohio Motor Co. as president and general manager of the Abbott Motor Co., which recently went into the hands of the creditors' committee. Mr. Zimmerman has been made vice-president and treasurer and, while no secretary has yet been appointed, this office will be filled before the end of the week. The committee reports progress and its actions have met with the entire approval of the creditors. The directorate will consist of nine, most of the members of which will be chosen from the creditors. The committee expects to complete the list of directors by the end of the week.

France's Exports Gain $2,602,380

PARIS, FRANCE, May 12—Although rumors of war have caused a falling off in home business, the automobile export trade of France continues to be good. According to the official returns, the increase in exports for the first 3 months of the present year, compared with the corresponding period of 1912 is $2,602,380. Four countries show a falling off in their purchases with France: England, $281,940; Switzerland, $77,340; Turkey, $19,880; United States, $26,460. All other nations show an increase, the greatest jump being with the Argentine Republic. The official figures for exports during January, February and March, 1912 and 1913, are:

	1912	1913
England	$2,859,360	$2,577,420
Belgium	1,918,560	2,339,520
Argentine Republic	448,700	1,194,360
Brazil	449,640	729,420
Germany	600,900	680,460
Algeria	769,860	945,120
Italy	114,240	281,700
Spain	219,060	252,540
Russia	63,840	247,920
Switzerland	262,380	185,040
United States	168,780	142,320
Austria	61,920	76,320
Turkey	59,580	37,700
Other countries	929,280	1,844,040
	$8,926,500	$11,528,880

Imports of automobiles into France have increased, the figures for the first three months of 1912 being $476,160, compared with $838,560 for the present year, being an increase of $362,400, or 76 per cent. The greatest increases have been obtained by England, Germany, Belgium, Switzerland and the United States. England has increased her business with France 125 per cent. during these three months and Germany shows an increase of 128 per cent.

Houpt To Handle Lozier in Metropolis

NEW YORK CITY, May 20—Harry S. Houpt, Inc., will after June 1st handle the Lozier car for New York and the Metropolitan territory, succeeding the present branch arrangement. Mr. Houpt, who is president and general manager, was until recently head of the sales department of the American Locomotive Co. With him is L. A. Van Patten, vice-president and salesmanager, and who is at present advertising manager of the Alco company. J. V. Westervelt will be secretary and treasurer of the new concern.

Westinghouse Report Shows Gains

NEW YORK CITY, May 21.—The Westinghouse Electric & Mfg. Co. published its annual report yesterday, showing gross earnings for the year ending March 31, 1913, of $40,000,000, $3,164,032 being available for dividend payments. After paying 7 per cent. dividends on the preferred stock, 8.2 per cent. remained for the common stock, as compared with 6.12 per cent. for the previous year.

Automobile Securities Quotations

Changes in price were rather mixed during the past week, and the amount of trading also varied with the several issues dealt in on the Exchange.

Matheson Sale's First Day Brings $81,000

Bid $310,000 for Columbus Buggy —Bergdoll's Sale Brings $45,062

WILKES-BARRE, PA., May 21—*Special Telegram*—The sale of the receiver of the Matheson Automobile Co., of this city, opened yesterday, under the supervision of W. C. Shepherd, former president of the company and now receiver. The total realized on the first day of the sale was $81,000, which includes $30,000 realized on business good will, trademarks, etc., patterns and drawings. The sale will continue through today and tomorrow, when finished cars and shop equipment will be sold.

The Matheson company went into the hands of the receiver some time ago. On April 21, the condition of the company's liabilities was as follows: It owed $200,000 first mortgage, of which $183,200, the interest on which totaled $4,268.56. The second mortgage amounted to $105,000, including outstanding bonds to a total value of $68,500 and interest.

Columbus Buggy Co. Sale Confirmed

COLUMBUS, O., May 19—Judge J. E. Sater in the U. S. Court late Monday, May 19, confirmed the sale of the assets of the Columbus Buggy Co., to D. N. Postlewaite, representing the creditors' committee at the bid of $310,000. The objection of the McCue company, a creditor, on the ground that more money could be realized, was overruled. Steps are now being taken to reorganize the company and operate the plant.

Bergdoll Assets Bring $45,062.87

PHILADELPHIA, PA., May 19—The 2-day sale in bankruptcy of the Louis J. Bergdoll Motor Co., southwest corner of Sixteenth and Callowhill streets, realized known assets of $45,062.87, with unknown assets scheduled at about an equal amount, which is considerably less than the scheduled liabilities of approximately $160,000. Judge Thompson, in the United States District Court, today confirmed the sale of the company's assets.

Allen Company to Make Car

FOSTORIA, O., May 17—The organization of the Allen Motor Car Co., with an authorized capital of $500,000, has been completed and the announcement is made that a car will soon be manufactured in Fostoria and placed on the market which will sell for about $1,350. The organizers of the concern are E. W. Allen, W. O. Allen, J. E. Wright, M. A. Thomas, O. P. Bernhart, George E. Schroth, Grayton Baker, R. J. Christy and H. C. DeRan.

To Make More Gasoline in Kansas

TOPEKA, KAN., May 17—A big increase in the output of gasoline from the tar stills of the Standard Oil Co. of Kansas, located at Neodesha, Kan., will mean a considerable decrease in the price of gasoline in this territory, according to Earl W. Evans, attorney for the company. The concern has just secured permission to increase its capital stock from $1,000,000 to $2,000,000, and will make extensive improvements in its plant, expecting to make it the largest refinery in the world. The largely increased production of gasoline, if it reduces the price, will prove a boon to automobile owners, who have recently been compelled to pay more than formerly for their fuel.

Powerene—a New Automobile Fuel

FINDLAY, O., May 19—A new product made from the by-product of natural oil wells, which has hitherto been considered useless, has been discovered by Dr. J. W. Rae and Reece Lockwood, of Bowling Green, O. It is claimed by the discoverers that their new product will do away entirely with gasoline for motor power purposes. The new discovery will be called Powerene. It is said that it can be manufactured for half the cost of gasoline and that it will give more energy than a like amount of the latter liquid. Its explosive power is much higher and it does not leave as great a deposit of burnt carbon, on account of the new stuff being less carbonaceous than gasoline.

On a trial run from Bowling Green to Tiffin, 84 miles, the cost was 36 cents. The stuff can be easily manufactured for 13 cents per gallon.

MILWAUKEE, WIS., May 17—The Acetylite Gas Co., of which Percy C. Avery, well known in the automobile illuminating field of America and Europe, is president and general manager, has established a plant in Milwaukee, where it will carry on its work, which includes the manufacture and filling of gas tanks for pleasure cars and trucks. Experiments are being completed with a new form of acetylene gas which may be used as fuel in motor car engines, but Mr. Avery is not yet ready to make public the details of the product. By a secret process the Acetylite company has developed an acetylene gas which gives a flame of intense white or bluish light, similar to the light of electric lamps. The new fuel is a development of this gas process.

Court Holds Acetylite Does Not Infringe

MILWAUKEE, WIS., May 17—The United States Court for the Eastern District of Wisconsin, Milwaukee, has dissolved the injunction issued against Percy C. Avery and George F. Burnham of Milwaukee in 1910, on petition of the Prest-O-Lite Co., in consequence of the recent decision of the United States Court of Appeals that the patent had expired in 1910, and further, that the gas tank and process of the defendants did not infringe.

Smith-Haines Enjoined from Using "Yale"

NEW YORK CITY, May 20—Smith-Haines, who sold locks under the name Yale without being empowered to do so by the Yale & Towne Mfg. Co., of this city, were enjoined from continuing this practice by Justice Geo. C. Holt, of the U. S. District Court, Southern District of New York.

Market Changes of the Week

The metal markets this week experienced quite a few important changes. Tin slumped to $47.88 per 100 pounds at a loss of $1.12 in price for the week, while both coppers dropped in prices, electrolytic $.00 1-5 a pound and Lake $.00 1-20. Antimony on Wednesday dropped to $.07 1-2 per pound, a difference of $.00 1-8 from the preceding week. Bessemer steel dropped to $28.00 a ton, a lowering of $1.00, while open-hearth steel experienced a drop to $28.50, a reduction in price of $.50 per ton. Lead remained quiet but steady, calling at $4.35 per 100 pounds. Cottonseed oil at the close of the week held steady in price, and again reflected the tone of the lard market, which showed no material change in actual prices, but with an undercurrent of steadiness. A gradual rise from $6.89 on Wednesday to $7.06 on Tuesday showed at the closing an increase of $.17. Domestic scrap rubber remains in a steady position. A fair demand is being received from reclaimers and a somewhat larger export movement has been noted of late. Stocks seem to be comparatively small. On call at the New York market, automobile tire scrap was selling at $.10 a pound.

Massachusetts Truck Bill Is Reported Back

Despite Opposition of Automobile and Business Men, Committee Brings $5 a Ton Bill Up Again

BOSTON, MASS., May 17—Despite all the arguments made against the truck bill by men of ability in different lines, and with no one representing the Highway Commission appearing in favor of it, the Committee on Roads and Bridges of the Massachusetts Legislature reported back the same bill calling for $5 a ton last Tuesday. It was evident from the questions asked by the members of the committee that they could not be convinced but what the motorists were wrong and the Highway Commission was right. But the fight will be kept up. If it passes the Senate a fight will be made in the House against it.

Massachusetts to Test Double Tax

BOSTON, MASS., May 19—Plans are now being formed in this city to test the constitutionality of the Massachusetts motor law instead of waiting for the outcome of the test case that the American Automobile Association is going to take to the United States Supreme Court. In the New York law all other taxes are exempted in lieu of motor fees, while here motorists pay personal property taxes as well as the registration tax, and the latter gives them no special privileges to go where horse-drawn vehicles are not allowed to go, but, on the contrary, they are restricted on many roads; while also other users of the highways pay no taxes except on property value.

Essenkay Products Change Hands

CHICAGO, ILL., May 19—*Special Telegram*—The Essenkay Products Co., 1125 West Thirty-seventh street, Chicago, has taken over all the business and the rights of the Essenkay company. The latter concern was the original promoter of Essenkay, a tire filler, which became fairly well known all through the country. Instead of using distributing agencies as before, the new company will introduce the plan of having supply houses and garages handle the filler.

NEW YORK CITY, May 17—The Manhattan Automobile Club, Inc., has opened its clubrooms at 222-224 West Fifty-ninth street to its members. A smoker is to bt given in the near future. The restaurant in the building has arranged to supply the members with meals a la carte.

Warner Announces New Clutch

MUNCIE, IND., May 17—The Warner Gear Co., of this city has added to its extensive line of automobile parts, a new enclosed clutch. The clutch, their model K-12, is of the dry-plate multiple-disk type, and is adaptable to the unit constructions of motors. The clutch housing does not run with the flywheel, but is stationary, being bolted to the motor housing.

The disks are of steel, faced with Raybestos. The drive is taken on hardened steel studs and hardened keys. All bearings are of the ball type.

Chicago's Municipal Underground Garage

CHICAGO, ILL., May 21—This city is planning a mammoth garage which will extend thirteen blocks along Michigan avenue, from Randolph street to Park Row, run under the surface of Grant Park and will house more than 2,000 automobiles. When completed it will be the largest garage in the world. The plans, drawn up by J. J. Reynolds, engineer of the harbor and subway commission, have been sent to the South Park Commissioners for their consideration. Whether they will be approved or rejected depends upon the action of the park board, which has sole jurisdiction over Grant Park. The estimated cost is $1,250,000. According to the present plans the garage will be constructed in sections, each section to accommodate 225 cars, with the cost of construction estimated at $125,000. Each section will be built between two east and west cross streets. The material specified in the plans is reinforced concrete, insuring permanence and proof against fire, and the roof will be covered with soil, so as to make a grass plot as at present. The cars will enter at one roadway and go out another, so that traffic will be in one direction except when a machine is backing out of its stall. The stalls, to be 16 feet long and 8 feet wide, will be arranged for the easiest entrance and exit.

Americans Lose by Slow Delivery

WASHINGTON, D. C., May 17—There are 2,000 automobiles in the republic of Uruguay, according to a recent official report. Of this number 1,300 are licensed in Montevideo and the remainder scattered throughout the country. Cars are entering the custom house at the rate of fifty a month. About half of the cars in use are of American manufacture. American cars are declared to be the more popular, but owing to the delay in delivery many orders are placed in Europe, where, it is claimed, shipment is made more promptly.

Vaughn Car Co. Working at Kingston

NEW YORK CITY, May 20—The Vaughn Car Co. has taken over the Kingston, N. Y., factory of Wyckoff, Church & Partridge, Inc., now bankrupt, and there will build a six-cylinder car, the Vaughn, which will retail at not more than $2,500. The officers of the company are: A. B. Cordner, president; Orlando Weber, vice-president; H. M. Johns, treasurer; Ernest S. Partridge, secretary and sales manager; Chester Griswold, consulting engineer.

Commercial Makers Plan Combination

NEW YORK CITY, May 20—The removal of the factory of the Lansden Co., of Newark, N. J., to Allentown, Pa., which has been announced here today, means not only that this company will considerably increase its capacity after having taken a one-story building having some 7,000 square feet, but it foreshadows a more important movement. The building which the Lansden Co. will use for the Allentown factory, belongs now to the Webb Fire Engine Co. This company, as well as the Maccarr Co., also of Allentown, are expected to combine with the Lansden Co. will use for the Allentown factory belongs now to the Webb manufacturer of self-propelling fire-fighting equipment and the Maccarr company makes a 1,500-pound wagon.

CHICAGO, ILL., May 17—W. T. Tennant, of Tennant Motors, Ltd., Chicago, agents for Simplex and Henderson, has been made vice-president of the Stewart Speedometer Corp.

NEW YORK CITY, May 20—On June 1 R. W. Hutchinson, advertising manager of the International Motor Co., will leave that company. So far he has not announced his future plans.

FINDLAY, O., May 19—R. K. Johnston has been retained to take the management of the manufacturing end of the Bowling Green Motor Car Co., Bowling Green.

Pedestrian Has Prime Right of Way

MEMPHIS, TENN., May 17—That a passenger leaving a trolley car has the right of way over an automobile has been decided in the U. S. Circuit Court of Appeals for the Sixth Circuit. Robert W. Parks, after leaving a street car and trying to gain the sidewalk, was struck by a cab of the Taxicab Company of this city. The latter, in its defense brought up in reply to the individual's damage action, argued that the accident was due to contributory negligence of the pedestrian, but the court ruled opposite and gave judgment for the plaintiff.

DETROIT, MICH., May 19—The Downing-Detroit Motor Co. is bringing out a racy-type design of cycle-car. The power plant consists of a 10-12-horsepower motor of long stroke. One chassis will be produced of standard tread and wire wheels, with a choice of either single or tandem seats. Arrangements are being completed to produce these cycle-cars in large numbers.

Practice for 500-Mile Race Is Under Way

Nearly All Drivers Are Tuning Up Their Racers at Speedway—Foreign Cars Turn Laps in 1:41

INDIANAPOLIS, IND., May 19—Those who have been watching the practice at the Indianapolis Motor Speedway are predicting that the average speed of the 500-mile race to be staged May 30 will be something less than 80 miles per hour, but over last year's mark. Among those who have made this prediction is Joe Dawson, who won last year's race at an average speed of 78.72 miles per hour. It is Dawson's opinion that, although some of the cars entered are capable of 100 miles an hour or better, they will be unable to maintain within 20 miles of that average on the local Speedway.

The Peugeots, driven by Goux and Zucarrelli, have turned several laps in 1:41, which has been the best mark since practice began in the present try-outs. The best lap last year during the race was 1:39 and many of the drivers are confident of equalling this before the race. Both Goux and Zucarrelli are delighted with the course. They say that, while they do not believe the course is capable of as great speed as Brooklands, they find driving less fatiguing here than on the English track.

The three Isottas will arrive tomorrow and will begin practice at once. Tetzlaff, one of the Isotta drivers, has been here several days, impatient to begin work. Grant and Trucco will be on hand when the Isottas arrive.

Gil Anderson and his Stutz are attracting a lot of attention during the practice. Anderson, a day or so ago, turned four laps, or 10 miles, in 6:57, which is said to be the best time for the distance that has ever been made on the course. Anderson has done several laps in 1:44 and his team mate, Herr and Merz, have also hit this figure repeatedly.

One of the criticisms of the Peugeot drivers has been that they have been trying to maintain approximately the same speed on the turns that they do on the straightaways.

Bob Burman in his Keeton is doing some steady and consistent work. Burman believes his car is ready for the race, although he expects to do some faster laps during practice than he has to date. His best lap has been 1:42 3-4, and he has turned other laps in 1:43 and 1:45.

The Mercer team, De Palma, Bragg and Wishart, have been at work several days. They have clipped off some laps at 90 miles an hour and their cars are working nicely.

Clark has practically overhauled his Tulsa and is now ready for some stiff practice. He found on arriving here that a number of changes in the car were advisable. Liesaw has been making some changes in his Anel, and Endicott has been making a few changes in his Case. No opportunity has been given thus far to show what the Case, Tulsa and Anel can do, but it is expected they will begin pretty active work by tomorrow.

The Fox Special, or Gray Fox, as it is being called by the railbirds, is being given a good work-out by Wilcox. Thus far Wilcox has been content to take the stiffness out of his motor, but by tomorrow or Wednesday he expects to begin showing some speed. Endicott and his Nyberg are not yet on the track. Reports have been received, however, that in practice work on country roads, Endicott has been able to get 92 miles an hour out of his car. The car will be on the track some time this week.

Harry Goetz has been selected as team manager for Billy Knipper, who is to drive the Henderson in the race.

Disbrow and Nikrent have been on the track several times with their Case cars, but have not tried to do much better than 1:50 for a lap. They have been trying to determine the size gear wheels they will need and, incidentally, to become thoroughly familiar with the track before attempting any fast work.

Johnny Jenkins has not done much actual practice with his Schacht, but has made a few trials and has made a few minor changes as a result. Mulford and his Mercedes will be here within the next day or two.

The Speedway management has announced the appointment of P. P. Willis as assistant director of contests at the Speedway. He will thus be first assistant to Charles Sedwick.

A new plan of signalling the drivers has been adopted. Heretofore the starter has had to flag the cars from the track. For this year a trolley arrangement has been built from the judge's pagoda to the paddock stand across the track and the flags will slide down to the center of the track. At the end of each driver's 199th lap a green flag will notify him that he has begun his last lap.

INDIANAPOLIS, IND., May 21—*Special Telegram*—F. L. Adams has withdrawn the Smada entry from the 500-mile race, being unable to get the car ready. Pennebaker and Nyberg have arrived. The unknown entry No. 32 is a Shambaugh, entered by Charles Shambaugh, of Lafayette, Ind., who entered a car last year but withdrew it before the race. The motor is a special four-cylinder type built by Shambaugh.

NEW YORK CITY, May 17—Albert Guyot arrived today on the steamer *La Provence* in company with H. L. C. Crossman, who will act as mechanician with him at Indianapolis on May 30. Guyot's Sunbeam racer has arrived and has been shipped to Indianapolis. Guyot has had much experience as a driver and is expected to give a good account of himself in the 500-mile race.

A. A. A Authorizes Pennebaker Entry

NEW YORK CITY, May 20—At a meeting of the Contest Board held at A. A. A. National Headquarters, Friday, May 16, the following action was taken:

The application for reinstatement to good standing of Theran S. Duby, of St. Louis, Mo., who was on December 14, 1911, disqualified and suspended until December 14, 1913, for participation in an unsanctioned track meeting at DeWitt, Iowa, on September 15, 1911, was considered and Mr. Duby was reinstated to good standing. Charles Shambaugh was also reinstated.

The ineligibility of Ernest J. Delaney, of Jackson, Mich., driver of the Cutting car in the 1910 500-mile race at Indianapolis, who took part in an unsanctioned track race at Milford, Iowa, August 14, 1912, was, upon his formal application, removed.

The application of R. H. Pennebaker, of Memphis, Tenn., who drove in the unsanctioned race meet held at the Tri-State Fair Ground's Track, Memphis, Tenn., July 4, 1912, was favorably considered and the acceptance by the Indianapolis Motor Speedway of his entry of a Pennebaker Special in the coming 500-mile race was authorized.

The request of C. V. Dunivan, of Memphis, the promoter of the meet in question, for removal of his ineligibility was considered, but his application was finally denied.

The application of E. V. Rickenbacher, of Des Moines, Iowa, for reinstatement to good standing was denied.

Upon satisfactory compliance with Rule 78, the board allowed and accepted the claim for record of Earl Cooper, driving a Stutz car, at the County Fair Grounds track, Fresno, Cal., February 10, 1913, as follows: 200 miles—3 hours 27 minutes 23 4-5 seconds.

The performance of Barney Oldfield, driving the front-drive Christie, in a 1-mile time trial at the new Bakersfield, Cal., 1-mile dirt track in 46 2-5 seconds, was not accepted as a new record pending the submission to the board of more complete data as to the construction and method of operation of the Pendleton automatic timing device, with which the trial was timed.

The sworn affidavits of E. H. Pendleton, chief timer; C. A. Colby, referee, and S. L. Mitchell, A. A. A. representative, to the correctness of the time was furnished, as well as the certificate of Civil Engineer J. L. Evans as to the distance, but the Contest Rules provide that no claim for record of 1 mile or under and up to 5 miles can be considered unless the timing is done by an automatic electrical or mechanical timing device *"approved by the board and the actual printed evidence taken by such device submitted to the board."* If these requirements are satisfactorily met the new mark will supersede the present record of 47 85-100 seconds made by Bob Burman in the Blitzen Benz II at Brighton Beach, N. Y., September 7, 1912.

The application of S. W. Gumpretz for sanction for automobile races in conjunction with auto polo games at Brighton Beach May 30 and 31 was denied.

The following summary of automobile contests for which official sanction has been issued in 1910, 1911 and 1912 was submitted by Chairman Schimpf:

	1910	1911	1912	Scheduled for 1913
Speed events (track and speedway)	88	60	97	12
Beach races	4	4	2	1
Road races	5	8	8	5
Hill climbs	20	14	6	3
Reliability	49	26	17	11
Non-stop tests and trials	..	3	2	..
Totals	166	117	132	32

The number of events scheduled at this time for the coming year shows the following increase over the number of events scheduled a year ago: Speed events, three; road races, two; reliability, four; hill-climbs remain the same and there is a loss of one in beach races, the Old Orchard, Me., meeting not being scheduled for 1913.

Winning National, which finished highest almost throughout

Paige-Detroit, which had the highest score in fuel economy

National Grand Winner in Catskill Run

Final Standing Catskill Tour

No.	Name	Price	Reliability	Hill-Climb	Economy
1	Mercer	$2,500	15	2:38.4	.260
3	National	2,600	0	3:46.8	.1628
5	Alco	6,000	0	3:23.5	.188
7	Ford	525	0	4:20.4	.206
11	Ford	600	0	5:16.2	.213
15	Mercer	2,500	0	Stalled	.196
17	Pathfinder	2,000	137	5:16.4	.180
20	American	2,750	0	3:42.6	.197
22	Oakland	1,215	0	5:02.8	.204
24	Paige-Detroit	1,275	0	3:52.2	.1627
34	Briggs-Detroit	900	148	No	.175

NEW YORK CITY, May 15—The combined Catskill reliability run, hill climb and economy test promoted by W. J. Morgan, the veteran promoter of contests, and conducted under the auspices of the newly-formed Motor Dealers' Contest Association, reached a successful conclusion this evening, all eleven of the competing cars which checked out yesterday noon having gone through the strenuous day and a half of competition in good shape.

The cars traveled 262.8 miles. The first afternoon's run to Newburgh was 64.7 miles, and in addition to testing reliability was also an economy contest, which was won by a Paige-Detroit with a percentage figure of .1627 obtained by dividing the weight of the vehicle with passengers into the ounces of gasoline used for the distance. The National was just beaten in the fourth place of decimals, its figure being .1628.

The second day's run was 198.1 miles, divided into forenoon and afternoon runs. The forenoon run was from Newburgh to Haines Falls in the Catskills, 63.2 miles. This occupied but a part of the time, the remainder being taken up with a hill-climb in which each vehicle had to compete, the driver alone riding. The hill was 1.1 miles long, very winding, with grades exceeding 20 per cent. and with a great many water breakers across the roadway. The winner of the climb was Mercer runabout No. 1 which made a remarkable climb in 2:38 2-5, or 44 seconds faster than the next competitor, which was the Alco touring car with a figure of 3:23.5.

The afternoon run of the second day was 135 miles, over good roads back to New York by way of Newburgh and Tuxedo.

When the eleven contestants checked in at the finish eight had perfect road scores. These were: No. 3 National, No. 5 Alco, No. 7 Ford, No. 11 Ford, No. 15 Mercer, No. 20 American, No. 22 Oakland and No. 24 Paige-Detroit. Each of these received a certificate of performance.

Besides a winner in the hill-climb, a winner in the fuel economy and winner or tied scores in the reliability, the rules called for a grand winner to be the contestant averaging best in all three contests. In deciding on the grand winner 600 points were allowed for a perfect score in reliability, 200 points to the winner of the hill-climb and 200 points to the winner of the fuel test. The other contestants were rated on a percentage basis proportional to their showing compared with the winner in each contest. In this grand classification No. 3 National was adjudged first with a rating of 938 points out of a possible 1,000. The Paige-Detroit was second with 936 points; the Alco third, 928, and American fourth with 907.

Under the rules each contestant carried an official observer throughout the contest, excepting in the hill climb when the driver rode alone. The reliability rules called for penalities for being late in checking in at controls, also for work done on the car when on the road such as repairing or replacing damaged parts. Motor stops were not penalized and there was not any technical inspection of the cars at the finish or any tests of brakes, clutches and gearboxes.

The economy contest proved one of the most interesting, in that the method of determining the winner gave the small car practically an equal chance with the largest machines. It would be difficult to select a better 65 miles for a fuel test. There is not a level mile in the entire stretch and just beyond West Point the contestants climbed Crow's Nest mountain, an ascent of 2 miles, with many hairpin turns so sharp that some of the larger cars had to reverse in order to get around the turn. In addition to sharp curves the road surface is soft dirt and there are water breakers every 50 feet, which compelled the cars to slow down. During the other part of the test there were many stiff climbs and much poor road, wornout macadam filled with pot holes 1 foot in diameter and often 6 inches deep. The speeds of travel were 12 miles per hour for cars under $800, 13.5 m.p.h. for those costing $800 to $2,000; and 15 m.p.h. for those costing above that amount. The cars were weighed previous to the start. The following are the results:

No.	Car	Weight	Gals.	Ounces	Percentage	Final standing	Miles per gallon
24	Paige-Detroit	3650	4	82	.1627	1	14.0
3	National	4200	5	44	.1628	2	12.1
34	Briggs-Detroit	3080	4	29	.175	3	15.3
17	Pathfinder	3690	5	27	.180	4	12.4
5	Alco	5780	8	65	.188	5	7.6
15	Mercer	3250	5	0	.196	6	13.0
20	American	4900	7	71	.197	7	8.6
22	Oakland	3350	5	44	.204	8	12.1
7	Ford	1880	3	3	.206	9	21.5
11	Ford	2400	4	0	.213	10	16.2
1	Mercer	3050	6	32	.260	11	10.4

These results show that the Ford runabout was the only contestant to exceed 20 miles to the gallon, making 21.5, a good showing for the roads. The method of determining the winner, namely dividing weight into gasoline used favors the heavier cars slightly in that the load carried is often better proportioned to the motor capacity than in light vehicles with fair-sized motors.

The winning Paige-Detroit has a four-cylinder motor 4 and 5 inches bore and stroke and uses a Stewart carbureter and Bosch magneto. No. 3 National, which finished so close a second, used a Schebler carbureter and Bosch magneto. Its cylinder sizes are 5 by 5 11-16. It has four cylinders.

The result of the hill-climb was practically a foregone conclusion from the start as Driver Ferguson has had much experience in handling a racing car. His roadster was stripped of fenders, but handicapped by a leaky radiator. He handled the machine well on the dangerous curves and over the water breaks. For timing purposes a telephone system connecting the starting line with the finishing line was used.

So far as the reliability run was concerned the eight perfect-score contestants had little trouble. The roads were dry from start to finish and not one of them had any difficulty in maintaining the schedule, which on the second day was 16 miles per hour for cars under $800; 18 miles per hour for cars costing up to $2,000 and 20 miles per hour for cars selling at over that price.

The three to receive road penalties were penalized not for defects in construction but for minor reasons. No. 1 Mercer developed a leaky radiator the first day and was penalized for taking on water outside of controls. No. 17 Pathfinder got all of its points but one for dirt in the gasoline line; and No. 34 Briggs-Detroiter discovered a piece of steel in the timing gears and also broke a torsion rod.

Revised and Corrected Score Grand Winner Catskill Tour

No.	Car	Reliability	Hill-Climb	Economy	Total
3	National	600	139	199	938
24	Paige-Detroit	600	136	200	936
5	Aleo	600	155	173	928
20	American	600	142	165	907
7	Ford	600	121	157	878
22	Oakland	600	104	159	863
11	Ford	600	100	152	852
1	Mercer	525	200	125	850
15	Mereer	600	000	160	760
17	Pathfinder	—85	100	180	95
34	Briggs-Detroiter	—140	000	186	46

In determining the grand winner a total of 1,000 points was allowed, of which 600 were given to the perfect score reliability, 200 to the winner of the hill-climb and 200 to the winner of the economy test. Each of the other contestants was awarded points in proportion.

In the reliability each point penalty against a contestant was equivalent to a deduction of 5 points from the 600 points allowed.

In the hill climb the points allotted each contestant after the winner were obtained on a percentage basis in which the winner was taken as standard. The fraction used had as its numerator the time of the winner and as its denominator the time of the other contestant, the time in each case being reduced to fifths of a second.

In the economy test the points allotted each contestant after the winner, were obtained on a percentage basis as in the hill climb. The fraction used had as its numerator the percentage given the winning car in the fuel test and as its denominator the percentage of the other contestants.

May Have 1913 Fairmont Park Race

PHILADELPHIA, PA., May 17—The preliminary move looking toward the restoration to the racing calendar of the Fairmount Park 200-mile road race was taken yesterday, when a resolution requesting the Fairmount Park Commissioners to act favorably upon the Quaker City Motor Club's petition for resumption of the event was introduced and unanimously passed by both branches of City Councils.

Whether there will be a 1913 race or not is now up to the commission, as that body, which last year abolished it, has the sole power of restoring it.

Expect 100 Glidden Tourists

MINNEAPOLIS, MINN., May 19—One hundred automobiles are expected to take part in the Twin City-Glacier National Park Tour for the Glidden trophy, which will start from this city on July 11 and will arrive at the park on July 19. The distance covered by the tourists will be 1,233 miles and they will pass through the states of Minnesota, North Dakota and Montana. A hotel train will travel shortly ahead of the tourists and will carry accommodations for sleeping and eating. With it a repair parts truck will travel, so that broken parts can be easily replaced in short order. Besides, a newspaper will be published, from day to day, with the assistance of the correspondents of papers participating in the tour.

The itinerary follows: July 11, leave Minneapolis; noon control at St. Cloud; night stop at Alexandria, Minn.; 144.4 miles. July 12, leave Alexandria; noon stop at Fergus Falls, Minn.; night stop at Fargo, N. D.; 123.8 miles. July 14, leave Fargo; noon stop at Grand Forks, N. D.; night stop at Devil's Lake; 194.6 miles. July 15, leave Devil's Lake; noon stop at Rugby, N. D.; night stop at Minot, N. D.; 135.6 miles. July 16, leave Minot; noon stop at Stanley; night stop at Williston, N. D.; 136.8 miles. July 17, leave Williston; noon stop at Poplar, Mont.; night stop at Glasgow, Mont.; 163.9 miles. July 18, leave Glasgow; noon stop at Malta. Mont.; night stop at Havre, Mont.; 156.1 miles. July 19, leave Havre; noon stop at Shelby, Mont.; night stop at Glacier National Park; 178.0 miles.

NEW OALEANS, LA., May 18—An offer of $5,000 as a prize for a 200-mile automobile race, which is to be the feature of the Galveston beach meet set for July 28, 29 and 30, is expected to draw enough of the stars in the game to make the event a great drawing card. In addition $9,000 in other prizes is arranged. Capt. J. W. Munn will have charge of the races. The meet will be a part of the Cotton Carnival.

DES MOINES, IA., May 17—The route of the fourth annual Little Glidden tour of the Iowa Automobile Association has already been tentatively agreed upon. The tour will leave Des Moines on June 23 and will make a day run over the state, covering in all a little over 1000 miles. Already more than thirty cars have been entered. This year a new departure will he attempted in that there will he two classes, one of factory ears, and another for owner-driven cars. The pathfinder for the tour will leave Des Moines this week.

Duration Motor Tests

WITH the completion of the 300-hour Packard motor test by the Automobile Club of America laboratory a movement has been instituted in this country which it is hoped will be carried forward and which, if properly directed, will do much to raise the efficiency of motors and also do valiant work in furnishing information concerning power plants which the American public, a good percentage of it at least, has been waiting for. Motor testing on the block for periods of long duration is new in America but it is bound to come in for increasing prominence because of the more general use of the dynamometer in factories and the wave of education on dynamometer testing that is being engendered at present. Only a year ago the Society of Automobile Engineers centered attention on the problem of motor testing in laboratories and at present a committee is active in this society in furthering this movement among the factories.

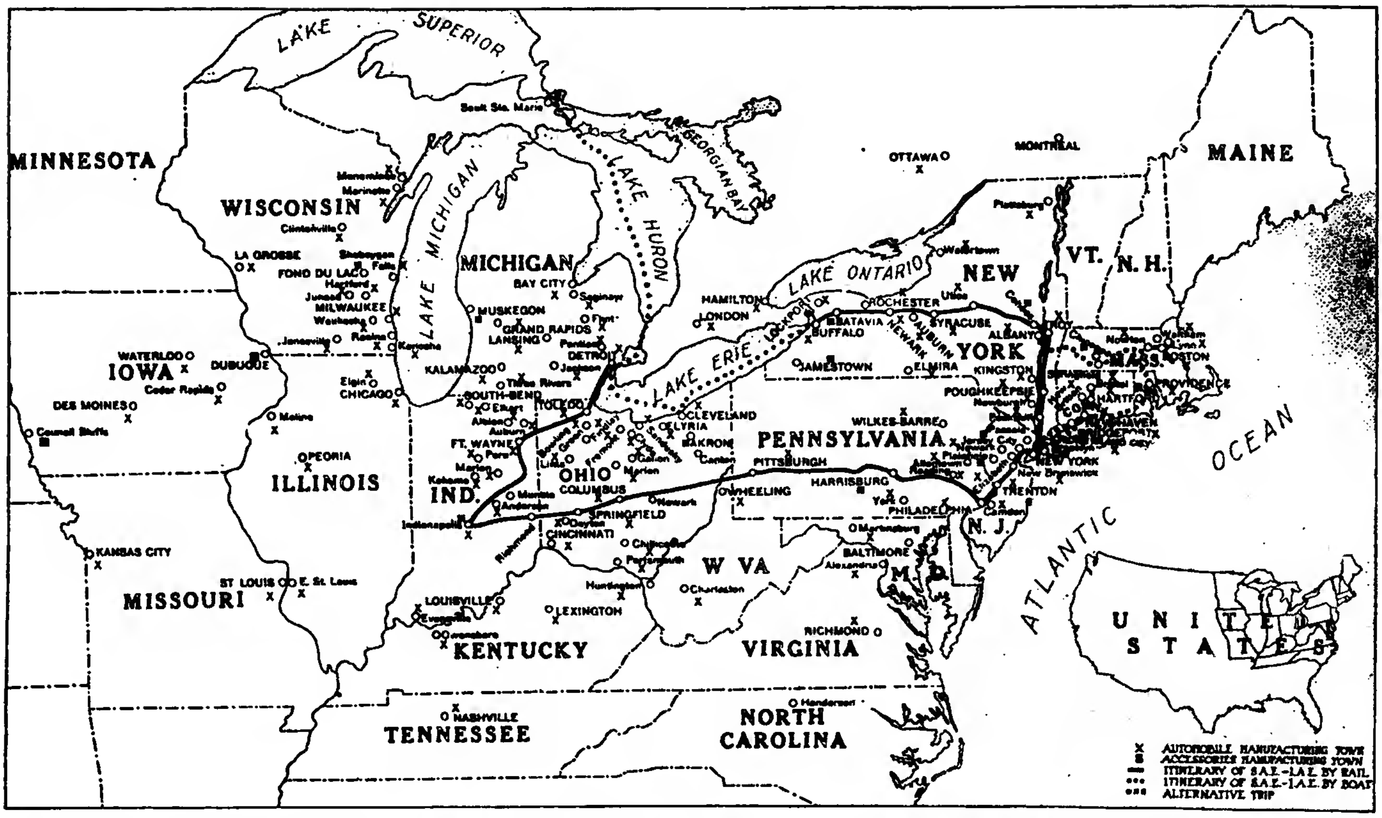
Duration motor tests made officially by laboratories not directly connected with any factory must be brought to some definite basis for comparison purposes otherwise these tests will be meaningless to the general public and the only purpose they will serve will be in enabling some factory to talk officially to the public in language that it desired to talk to such public before the start of the test. If there is not some basic regulation on such tests, each concern can hold a test according to is own whims, whims perhaps largely dictated by merchandising considerations. Permit such and you will effectually kill duration tests before they have grown out of their swaddling garments. Motor tests, made officially by apparently disinterested laboratories or technical schools, must aim at serving to elevate the general plane of engineering testing rather than being factors for other uses.

There is no reason why a few basic essentials might not be the same in standardized duration tests. Why should not the motor be required to show the official S. A. E. horsepower rating from start to finish. This is generally, in fact nearly always, the advertised rating, and because of this it is but logical that the motor under test should average this horsepower output from start to finish, at the piston speed at which such horsepower is supposed to be generated under the formula used in calculating. Making this one factor alone standard, it will give the public a basis of comparison which it must have if such tests are to continue. Let each factory set its own power rating and you will have at the end of the year a meaningless jumble of figures.

You cannot stop the public from comparing. It is one of the mental processes in the acquirement of knowledge. You cannot get a definite concept of anything without passing through the process of comparison.

Now that duration tests have been started it is to be hoped that efficiency and power tests will be started also. There should be a differentiation between them. In a duration test it is understood that the motor is not developing its maximum power, in power tests there should be a load much in excess of the official horsepower rating of the motor. Instead of a motor in a power or efficiency test pulling but its S. A. E. rating it should be compelled to pull 25 or 30 per cent. more than its rating for any period of hours that the maker might desire. Efficiency tests should also go further and show the frictional losses, the amount of power necessary to drive the rotating and reciprocating parts; the volumetric efficiency at various speeds and many other facts. In such a power or efficiency report every detail should show, whereas in a pure duration test made with a much lower horsepower load the horsepower generated, crankshaft speeds and fuel and oil consumption are practically all that should be given in addition to the general story of any alterations, adjustments, etc., which might be permitted under the rules.

The Automobile Club of America is to be congratulated on starting such a series of tests and the Packard company is also to be congratulated for setting the ball rolling. It is to be hoped that others will soon follow. In future tests greater care should be taken in conducting the test. The present testing laboratory of the club is too small to admit the visiting public. The testing room should be three times as large. The motor under test should also be better protected from visitors. There is no reason why a motor being tested should not be screened off, making it absolutely impossible for anyone but the officials connected with the test to get within 6 or 8 feet of it. Whenever the public is permitted to close in and lay hands on a motor undergoing such a test there is sure to be a storm of criticism. Many details will be misinterpreted and misunderstandings will arise. In such a test it is desirable to have duplicate sets of record keepers; and there should at all hours be some leading test official in charge.



The above map, which is similar to the one presented to the Society of Automobile Engineers and their English visitors, the Institute of Automobile Engineers, for use on their trip by THE AUTOMOBILE, shows the section of the United States and Canada in which are located practically all of the automobile and accessories factories. The itinerary of the engineers is clearly shown, the journey by rail in black and that by boat by the dotted lines, while the square dots indicate the alternative trip through New England. The cities marked "X" are automobile or motor truck manufacturing towns, while those marked with a square are accessory towns. The relative size of this section of the country is shown in the smaller map of the United States

Twenty-five English Engineers Sail for America

NEW YORK CITY, May 19—At a meeting of the entertainment committee of the Metropolitan Section of the Society of Automobile Engineers held here last night, the final details of the local program for the entertainment of the English engineers were closed. A cable has announced that twenty-five of the Englishmen were aboard the *Minnewaska* when she sailed last Saturday. The boat is expected to arrive in New York at about 10 a. m. Monday, May 26. In addition to the program which has been announced the committee has prepared a list of places which can be visited in the event of a rainy day or an interruption in the regular program. The places included in the list are as follows:

Brewster's body factory in Long Island City; Thomas A. Edison's plant in East Orange; New York Telephone Co.; Peter Doelger's brewery garage; Jacob Ruppert's brewery garage; Ward's bread factory; the New Grand Central Terminal; New York Edison Co.; General Vehicle Co.; American Express Co.

About a dozen starter manufacturers have consented to read 10-minute papers before the meeting on Tuesday night in the ballroom of the Hotel McAlpin and the discussion on these papers will be carried through after all the papers have been read.

The party includes four ladies. Those sailing are: T. B. Browne, president of the Institute of Automobile Engineers; T. C. Pullinger, Paisley, Scotland, and Charles Wheelers, London, members of the council of the Institute; Basil H. Joy, secretary of the Institution; and members, associate members and guests include: F. S. Bennett, London; C. A. Branston, Cambridge; H. Massac Buist, London; E. G. Davison, Cleveland; J. B. Ferguson, Belfast; J. Inglis Ker, Glasgow; E. C. Paskell, Birmingham; J. A. Prestwich, Tottenham; E. B. Wood, Bristol; Lucien Bollack, Coventry; E. Wooler, Bristol; Carl F. Benson, Coventry; J. B. Dunlop, Dublin; F. E. Filer, London; G. Gilbert Moore, Twickenham; Tom Norton, Llandrindod Wells; R. W. Smith, Redditch; T. Clarkson, Chelmsford; and Mesdames Pullinger, Wood, Browne, Clarkson and Mr. Smith, Jr.

Alexander Craig is managing director of the Maudslay Motor Co., Coventry, and has been connected with the industry since its inception. T. V. Pullinger is manager of the Arrol-Johnston Co. and has been long connected with the industry in France and England. F. S. Bennett is responsible for the Cadillac business in England. H. Massac Buist is a well-known journalist. Carl F. Benson is manager of the Humber works at Coventry. J. B. Dunlop is inventor of the pneumatic tire. T. B. Clarkson is designer of the Clarkson steam omnibus now being operated in London. R. W. Smith is managing director of the Enfield Cycle Co. J. A. Prestwich is constructor of the well-known J. A. P. motorcycle engines.

New England Electric Car Convention

BOSTON, MASS., May 21—The first New England convention of men identified with the electric field, comprising representative of central stations, makers of motor vehicles and allied interests, opened here at 1 o'clock yesterday afternoon at the Engineers' Club. It was attended by men prominent in all the lines from different parts of the country. W. H. Blood, Jr., former president of the Electric Vehicle Association of America, called the meeting to order and there were more than 100 on hand.

There were three sessions on the program, one yesterday afternoon, another last evening and a third this morning. The first session was given over to addresses and discussions under the heading "Electric Vehicle Progress." H. H. Rice, of the Waverley Co., Indianapolis, Ind., spoke on "The Growing Popularity of Electrics." Fred H. Kimball, of the General Electric Co., Boston, Mass., delivered an address on "New England as An Electric Vehicle Field," and President W. C. Anderson of the Anderson Electric Car Co., Detroit, Mich., spoke about "How a Control Station Can Develop Its Electric Vehicle Load." There were discussions after each paper.

The second session last night had "Salesmanship and Service" as the topics. E. R. Davenport, of the Narragansett Electric Light Co., Providence, R. I., spoke on "Constructive Criticism"; Louis Burr, of the Woods Electric Co., Chicago, Ill., had for a topic "Proper Selling of Electric Cars," and L. B. Wallis, of the Edison Electric Illuminating Co. of Boston, talked on "What Service Should the Central Station Furnish Owners of Electric Cars."

This morning the session was devoted to "Advertising." F. Nelson Carle, of the General Vehicle Co., Long Island City, N. Y., spoke on "Advertising the Electric Vehicle from the Manufacturer's Standpoint," and E. W. J. Proffitt of Providence, R. I., talked on "The Electric Vehicle as an Advertising Proposition from the Central Station Standpoint."

The Engineering Digest

A Digest of Technical Information from the Engineering Journals

GASOLINE Motor with Plane Slide Valves.—When the progressive engineer studies specimens among the multitude of valveless motors—meaning all non-poppet valve motors with the exception of the standard types of two-cycle motors—he frequently finds it difficult to perceive that any other object than that of finding an acceptable substitute for the poppet valve has been kept consistently in view by the designer. He realizes that the fashion element has been unduly influential in his field of work and that the great majority of new-type motors are therefore destined to perish in the struggle for survival, but also that an imitative or a fashion movement of this kind, with its 95 per cent. of waste, so far as applicable and practicable results are concerned, was necessary not only for the improvement of poppet valve motors, whose makers were getting satisfied to rest on their laurels, but particularly in order to bring to the surface the very small percentage of really promising construction which after all in the long run pays for the waste and much more. In some few instances a definite technical object has actually inspired the designer before his creation took form, although more frequently a merely possible design took form first and its technical objects were discovered afterwards, or were worked into it by successive modifications.

These reflections are suggested by a description of the Neute motor presented by Henri Petit. It is not clear whether this motor exists on paper only or has been made and tested, nor whether its weight can be kept within the limits considered ruling for automobile motors. An estimate on the basis of the accompanying drawings must satisfy the reader on these points.

The object aimed at by Mr. Neute has been to incorporate in one type of motor the greatest possible number of the desirable qualities now found represented individually in all the different types and makes of automobile motors and, above all, to secure unfailing reliability. In the largest sense of this word it involves that every working part of the motor can be inspected, cleaned and dismounted, on the road as well as in the garage, as often as the man in charge of it may desire, in the shortest possible time, with the simplest tools and without possible disturbance of its adjustments—those of the valve timing especially.

It is a four-cycle motor. The piston works in an ordinary water-jacketed cylinder. The cylinders are cast in pairs, and each cylinder A has a port *a*, serving for the passage of both fresh and exhaust gases, and a lateral casing *b* in which the whole valve mechanism is contained. The inner wall *c* of this casing, adjacently to the water-jacket, is ground perfectly plane and smooth. A piece B called the distributer-box has on one side a large ground surface in contact with *c*, a recessed middle portion in which the plane plate C is slidably inserted, and it faces outwardly against two slide valves D and E which are plane and can slide one upon the other. The conduits *d*, for the fresh gas, and *e*, for the exhaust, are cast in this box B and merge into one in line with the port *a* leading into the cylinder. The position of B is determined vertically by flanges *f*, forming part of the cylinder casting, and laterally by a spline *g* located between the two cylinders of a pair. The box B does not touch the casing *b* at its lateral and upper edges, which are left rough, expansion being facilitated by this provision. Contact between B and the plane-ground outer cylinder wall *c* is secured by the coverplate F which also regulates the necessary play between slide-valves D and E. The intake and exhaust manifolds G and H are mounted upon F, and the latter is secured to casing *b* by eight bolts b^1. The carbureter I is hung from the intake manifold.

It follows from this arrangement that the valve mechanism can be examined by merely removing the coverplate, together with the parts secured to it after separating the exhaust tube from the exhaust manifold and the carbureter from the gasoline inlet pipe and the throttle control.

Plate C, which is termed the stopper-plate, has a vertical displacement of 10 to 15 millimeters, and only a single orifice. It is controlled from cam *h* through a tappet rod J with a roller. A spring K takes it back to its lower position. The slide valves D and E have each two ports to determine the flow of gases and are controlled by the rods L and M, which for the sake of clearness are merely indicated by their positions in Fig. 1, these rods being in turn governed by two eccentrics e^1 and e^2 which are keyed upon shaft N, 70 degrees apart. Shaft N is a two-to-one shaft run by silent chain from the motor shaft. The cam *h* for the control of the stopper-plate is formed (see Fig. 8) upon the cheek separating two of a pair of the eccentrics e^1 and e^2.

The function of the stopper-plate is to be interposed between the cylinder and the slide-valves, so as to isolate the latter completely from the explosion chamber at the proper periods and protect them from pressure and heat. The cam *h* is so shaped (see graphic schedule of the cycle of cam actions in Fig. 2) that the port *a* in the cylinder is always uncovered a little more by the stopper-plate, for induction or exhaust, than by the respective slide-valve plates, and as to hold the stopper-plate at rest in its highest position at the end of compression and during the working stroke.

The movements of slide-valves and stopper-plate are indicated in the diagrams composing Figs. 2 and 3. At the end of the period for gas admission (diagram 1), which takes place when ports *i* and *j* register, cam *h* begins to raise the stopper-plate, and the lower edge of its port is displaced across port *a* at the same rate of speed at which the slide H valve D is moved which regulates the closure of gas admission; only the port in the stopper-plate is slightly behind in this movement.

At period 2, while port *a* is completely closed, the plate C still has 2 to 3 millimeters left of its upstroke. At periods 3 to 5 (including the position shown in diagram 4), the latter just preceding the opening of the exhaust, the stopper-plate remains stationary, the acting portion of the cam being circular and concentric with the shaft N. When 5 is reached the plate is dropped by the cam and is taken to its lowest position by spring K. The expansion of the gas is at that moment almost completed.

With regard to the pressures acting against the movements of the stopper plate, it is noticed that from 1 to 2—during the admission—the plate has its largest displacement, equal to 4/5 of its total stroke, and that this is effected without any resistance; that from 2 to 3, during the compression, the displacement is small, amounting to 1/5 of the stroke and taking a relatively long time, while the resistance is small, being determined by a maximum pressure of ½ kilogram per square centimeter of the stopper-plate edge; that from 3 to 5 there is no movement and, finally, that at 5 the spring action takes place under a resistance of about 4/10 kilogram per square centimeter.

The gas-tightness of the compression chamber is assured by the fact that, from the moment when the admission is closed and until the gas pressure ceases, the plate is pressed against the bottom of the distributer-box, where, moreover, as will appear later, the lubricating oil also contributes to the obviating of all leakage.

The mechanical conditions of this valve system are also particularly favorable. The frictions are of cast iron upon cast iron. The different pieces and walls engaged in the frictions are approximately of the same thckness and shape and undergo similar expansions and contractions by variations of temperature, so that the play once provided between the parts remains constant. The stopper-plate and the slide-valve plates are light of weight and perfectly guided, and the lightness of the slide-valve plates—weighing from 3/10 to 4/10 kilogram—admits of using control rods of corresponding lightness for operating them. These rods also work in an almost vertical position and exert no appreciable oblique pressures on the valve plates, so that it seems that they should last as long as the motor. With regard to accessibilty and easy dismounting, it is noticed that the stopper-plate is not jointed to its control but simply rests on it, like the valves in poppet-valve motors, the exact nature of the connection being shown in Figs. 5 and 6; also that the distributer is simply held between the outer cylinder wall and the coverplate without use of screws or bolts. and that the two manifolds are secured to the coverplate. No other tool than a single spanner or wrench is thus required for taking the whole valve mechanism apart or for mounting it. The only parts to be disconnected first are the carbureter from its control, the exhaust manifold from the exhaust pipe and the 8 bolts holding the coverplate F. The whole operation requires only a very short time—a few minutes for one familiar with the mechanism—as the details have been thought out with special reference to this high degree of accessibility. Even the guide of the tappet-rod for controllng the stopper-plate can be removed by first loosenng the bolt O (see Fig. 6) where after the whole rod can be lifted out and a single pin *t* holds the upper part of the control rod (Fig. 5) to the lower part J (Fig. 6). If it is desired to remove the slide-valve plates, it is not even found necessary to use a split-pin chaser to separate them from the control rods, as the relative movements of the two plates during operation of the mechanism is such that the spindles of the rod-knuckles cannot come out, one barring the way for the other, while each of them can be pushed out when the plates are separated. The working relations of these parts are shown in Fig. 7.

It is particularly worth noting that the valve adjustment cannot be changed by dismounting and remounting the parts and that it is unnecessary to drain the water from the jackets, to disconnect the gasoline manifolds, the carbureter or the cylinders.

A water circulation by thermo-syphon system is provided and ignition by magneto operated by silent chain in front of the motor.

The nature of the valve-mechanism in this motor further admits of instituting a motor-brake system by lodging an additional plate between the slide-valve plate E and coverplate F,

THE Wittig Rotary Steam Engine.—In a recent issue reference was made to the Wittig steam turbine or rotary machine as one whose simplicity might suggest possible applications for transportation work, especially if the thermic efficiency of the steam generation is brought down to a new basis on the system of the Bonecourt flameless surface-combustion or one equally advanced. A subscriber requests more information about the Wittig construction, and it should be said first that the Wittig motor is not a turbine except in the sense of being rotary. On the other hand it is not only a steam engine but works equally well as a water pump, an air compressor, a blower or a gas compressor or as a hydraulic motor. It can also function as a compressed-air engine. The only difference between its mode of operation as a motor and as a transmitter of power lies in the direction of its rotation and the direction of the fluid, steam or gas circulating in it. Fig. 11 shows it as a motor. This illustration and the following reference to its peculiarities are taken from *Le Génie Civil* of August 17, 1912.

The practical utility of rotary machines, other than turbines proper, is usually impaired by a certain defect. It is almost impossible to secure tightness between the vanes and the fixed cylinder without reducing the play between these organs to such a point that the frictions become excessive. This inconvenience seems to have been overcome in the rotary machine which has now been turned out for several years at the Karl Wittig works at Zell, near Wiesental, Baden. This machine is composed essentially of a fixed cylinder *b*, in the interior of which there turns an eccentrically mounted cylinder *a* formed with a series of deep radial slots in which are lodged the vanes *c* which function as pistons. As the number of chambers formed between the two cylinders by means of the vanes is considerable, the variation in the pressures existing in two adjacent chambers is reduced. The vanes assume their varying positions in the slots solely by the action of centrifugal force. As, however, this force, which grows with the speed of rotation, might press the vanes too energetically against the walls of cylinder *b*, such an effect has been obviated very largely by surrounding all the vanes by a metal ring *d* which is rotated with a certain amount of play in a recess turned in the wall of cylinder *b*. In this manner excessive wear of the vanes is avoided, at the same time as continuous contact with the interior of cylinder *b* is assured, owing to the eccentricity of the vanes and the ring as a whole.

A tight joint along the line of contact between cylinders *a* and *b* is also assured without it being necessary to reduce the play between them.

The admission and discharge of the steam, gas or fluid used in the machine are effected without intervention of movable organs, simply by means of circumferential slits giving access to a larger or smaller number of the compartments between the vanes. If the medium used is incompressible, these two slits, one for admission and the other for discharge, extend over the larger portion of the circumference of the exterior fixed cylinder, but the length of the slits is reduced if the medium is compressible and it is made smaller in proportion as the tension of the medium must be more fully utilized.

When this machine functions as a steam motor, its efficiency is said to be comparable to that of reciprocating engines of similar power.

—

COTTIN-DESGOUTTES Wheel Drive.—Unless great facility for removing and perhaps replacing a wheel shaft is considered a matter of great importance, the Cottin-Desgouttes system for combining the advantages of the floating shaft with those of the older types, in which the centering of the shaft in the wheel cannot be questioned, may present points of interest though mainly where ball-bearings for the wheels are still preferred to roller bearings. The characteristic feature, as shown in Fig. 9, is the enlargement of the axle-end constituted by a steel box bolted to the flared end of the axle proper, this box containing a double ball-bearing which is almost in alignment with the wheel tread and also prevents the wheel from coming off, and serving as base for the brake action in a very substantial manner, while keeping surplus lubricating oil from flowing to the brakes by providing a trough for it in the lower portion of the box.—From *La Vie Automobile*, May 3.

—

BALLET'S Shock Absorber.—The idea of making the shock absorber help in supporting an increased load is finding expression in the type designed by Ballet which is shown in part in Fig. 10. Two coil springs D placed in pistons C with rollers *c* are compressed with a minimum of friction when the cam A is turned by a crank and rod which are automatically operated in the customary manner when the vehicle axle is raised or lowered in relation to the vehicle frame. The shape of the cam seems to indicate that the desired effect is a progressive spring resistance and assistance in carrying an overload rather than the retarding of the recoil after a severe shock. The recoil or spring-extension is in fact accelerated at first. But the moment the recoil would carry the vehicle spring beyond its best position, the cam provides an energetic resistance. The overload capacity is necessarily small so as not to interfere too much with the mobility of the spring under normal conditions.—Illustration from *Omnia*, May 3.

—

Troubles with Omnibuses.—Complaint has been made to the municipal council of Paris that the seating offered each passenger in the motor omnibuses of that city is far too scant and that the shakings which are received when the rubber tires are worn down to one-half of their original thickness are positively dangerous; finally that the wheels are too small and thereby aggravate all shocks.—From *Le Poids Lourd*, March 21.

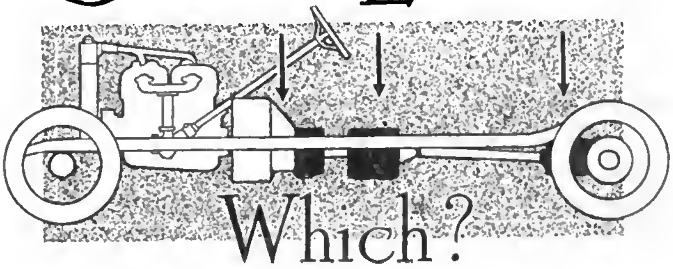
The Engineers' Forum

Gearbox Location



Part IV

Skidding Danger Is Minimized by Proper Location of the Gearbox

COMMUNICATIONS are still coming in from engineers and automobilists interested in questions of design regarding the best location of the gearbox. The preceding articles showed the remarkable diversity of opinion in engineering circles on this important particular of automobile construction. Herewith are given some arguments in favor of placing the gearbox on the rear axle:

Rear Axle Type Simplifies Chassis—Robertson

BUFFALO, N. Y.—Editor THE AUTOMOBILE:—In view of the present very marked tendency on the part of automobile engineers in general to simplify the chassis as much as good mechanics will permit, it is not surprising that there should be such a strongly-shown inclination to place the gearbox in combination with one of the two units that it connects. By so doing, one eliminates one piece of shafting, two universal joints, and, in some constructions, two oil retainers and one or more expensive bearings. The parts eliminated are particularly objectionable, as in the usual arrangement their exposure to dust and dirt and their commonly inadequate lubrication makes them particularly prone to wear and become noisy and their up-keep as a consequence somewhat of an item.

Either of the two unit constructions has the advantage of greater cleanliness, owing to the fact that there are two less points at which oil can escape.

As to the effect on the car's operation, of the location, of the weight of the gearbox, one has but to consider how much effort would result from a person of less than ordinary weight moving forward or backward a few feet in the car while it was in motion. Compared with the importance of the change in weight distribution in putting on a heavy limousine body the importance of the location, of the weight of the gearbox would almost seem negligible. The location of an electric lighting and starting battery would be of more importance. The rear axle gearbox unit has in its favor the greater silence resulting from the failure of the gear noises to reach the larger masses of the chassis and body which act as sounding boards for all the sounds that reach them. The rather elaborate gear control linkage is against the rear axle unit, however, and in many instances the oscillation of the car springs is communicated to the sliding gears resulting in indefinite gear location. The fatal defect of the rear axle gearbox unit, however, lies in the tremendously reduced ability of the car to perform on rough or uneven road surfaces. Some years ago the writer tried to drive a certain very high class car whose superb motor is the envy and despair of its competitors, but whose gearbox is located on the rear axle, over a very steep and roughly-paved hill on high gear. Not only was the feat well-nigh impossible, but so great was the abuse which the car sustained due to the excessive bouncing and pounding of the rear axle system, that the feat was not again attempted until it occurred to the writer to let considerable air out of the rear tires. Not only was the feat accomplished easily after that, but with the added handicap of starting at the bottom of the hill on high gear. At other times the writer has noticed how much at a disadvantage the cars, whose gearboxes were in the rear, were on the road. Once, on a short 2 days' trip through the mountains of Pennsylvania in company with a chain-driven car of German make, the writer, who was driving a car with a particularly heavy rear axle gearbox unit, had a splendid opportunity for studying under extreme conditions the comparative effect of the lightest and the heaviest types of axles. Suffice it to say that the chain-driven car was at all times master of the situation even on roads so rough as to compel the other to resort to gear work continually. Summing up, it would seem that advantage would all be with the motor gearbox unit up to such powers as would make the use of shaft as final drive of doubtful advisability.—PHILIP ROBERTSON, Y. M. C. A.

Put the Weight on the Driving Wheels—Duryea

SAGINAW, MICH.—Editor THE AUTOMOBILE:—I have read with interest a number of expressions on gearbox location, and I see that one writer favors distributing the weight because this lessens skidding. It has been nearly a score of years since visions of expensive, broken plate-glass flashed in front of me when my motor vehicle suddenly skidded and I have given continual attention to the matter since. I am certain that my product for the last dozen years demonstrates daily that the best prevention of skidding consists in placing the greatest part of the weight on the driving wheels, and that on this account the vehicle will be less likely to skid if the gearbox is placed on the rear axle; and further, that the rear tires will last longer. I have made motor vehicles with almost every possible proportion of weight on the front and rear axles. From the delivery rig, having the motor, tank and driver on the front wheels, with practically nothing at the back when not loaded, to a convertible four-passenger car carrying the rear passengers well behind the axle, and carrying the motor slightly in front with water tank directly over the rear axle. This proportion of rear weight was so great that on a steep hill there was some question as to whether or not the front wheels would remain on the ground. This experience repeated many times, has demonstrated that the best results are obtained with probably three-quarters of the weight on the driving wheels, and that when thus loaded they seldom skid. So certain has this freedom from skidding been that I have never owned or carried regularly a pair of tire chains, and have seldom found a road condition that my vehicle would not negotiate successfully without chains.

You can easily test this for yourself by attempting to push something on a slippery floor. Your feet not being heavily loaded slip badly, but take the load on your shoulders and you walk with certainty over the same slippery surface. The vehicle with the heavily loaded rear does not skid. Its tires are not ground away by its skidding wheels. Its front end is much easier to propel because it is not forced deeply into soft roads. The rear location for as much weight as possible is undoubtedly the best one.—CHAS. E. DURYEA, president, Duryea Motor Co.

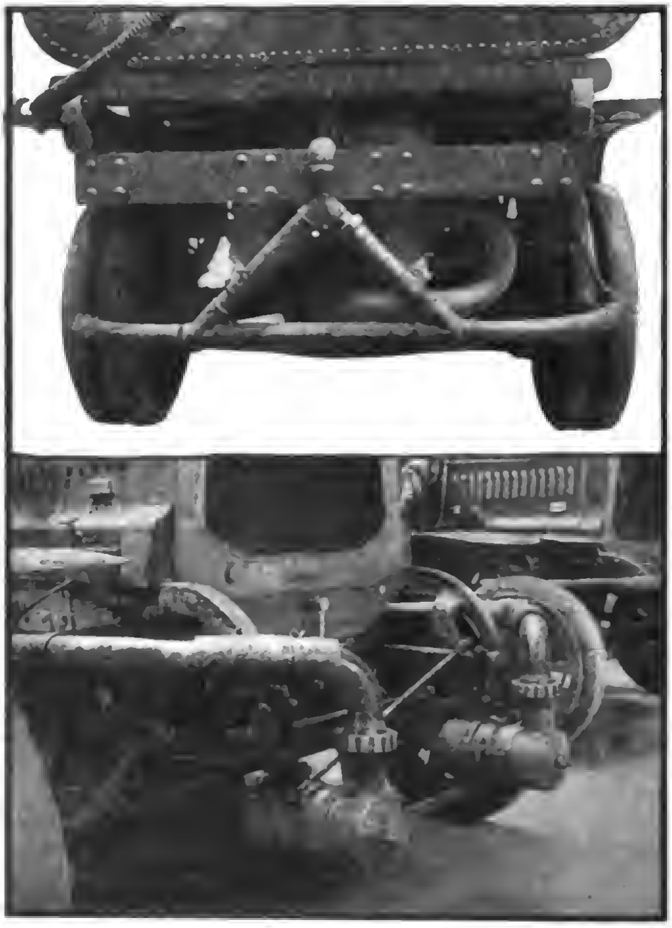
Motor Sweepers Save 12 to 60 Per Cent.

Use of Modern Street Cleaning Devices in Paris and Versailles Reveals Marked Economy as Compared with Old Methods

PARIS, France—It is part of the world's economy that the horse should disappear from the work of cleaning, sweeping and watering the streets and avenues of great cities. This is quite natural, for the horse itself is responsible for at least three-quarters of the dirt to be found on paved streets. Paris has proved it with the Champs Elysees, the automobile section of which never has to be washed and rarely has to be swept, while the adjoining alleys have to receive a daily toilette. Paris is the first city to make use of motor vehicles for street cleaning to the entire abandonment of the horse. The change is not yet complete, but in five of the twenty wards into which the city is divided the horse has gone entirely from the street cleaning department. The other districts have either made a partial change or have decided to convert as soon as present contracts have expired.

The determination of the correct type of machine for street cleaning necessitated a considerable amount of experiment. It was not merely a question of connecting up a motor to a four-wheel chassis driving a rotary brush. This was attempted at first, the city purchasing light, low-power rotary sweepers to replace the one-horse rigs in use for so long; and big motor-driven water-wagons for street sprinkling. It was found that the former raised as much dust as they swept, and that the latter could only be used to advantage in specially wide avenues a few days a year. This experimental work resulted in the adoption of a combination type of sweeper and sprinkler, capable of service throughout the year, wet or fine, rain or snow. The eighth ward, which is the most fashionable district of Paris, comprising the Champs Elysees and the Place de l'Etoile, was the first to make a complete conversion. The work in this ward is accomplished by seven De Dion Bouton machines, replacing from fifteen to twenty-five horses. Under the old system the number of horses was a very variable quantity, owing to the inelasticity of this method. During spring and fall fifteen horses could do the work; in summer and winter twenty-five horses were not always sufficient.

Taking the eighth district as typical of the entire city, the day's work comprises 10 hours, the machines going out at 4 a. m., stopping for 2 hours in the middle of the day, and entering the depot at 4 p. m. The same man is kept in charge of each machine and only skilled drivers are employed, the men having had experience with gasoline trucks being preferred. Drivers of the old horse rigs are not trained to handle the motor sweepers. The nature of the work varies largely according to the weather, the task given to each driver being chosen at the discretion of the overseer.

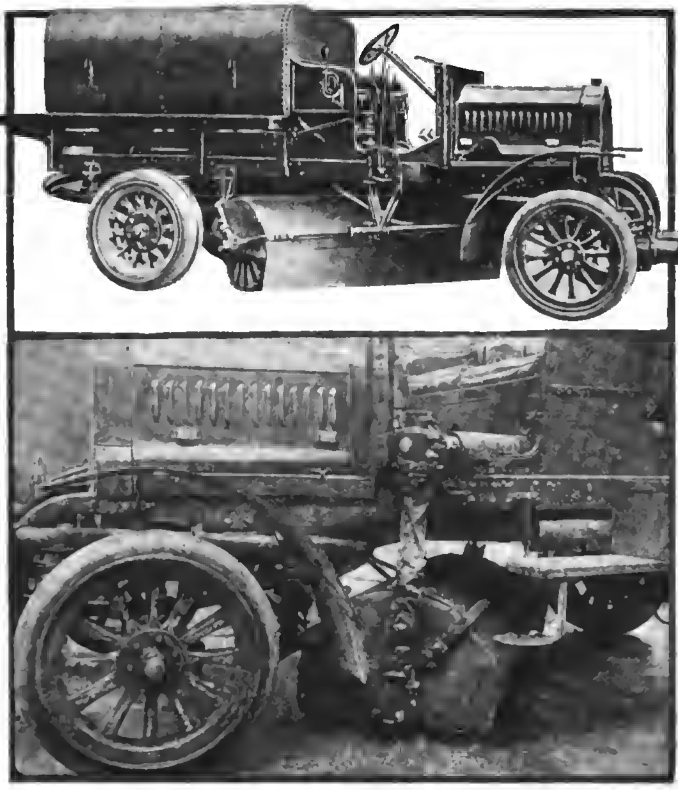


Upper—Rear view of motor street sweeper. Flow to transverse sprinkler is direct from tank by gravity. Lower—Detail of forward sprinkler on Paris street sweeper

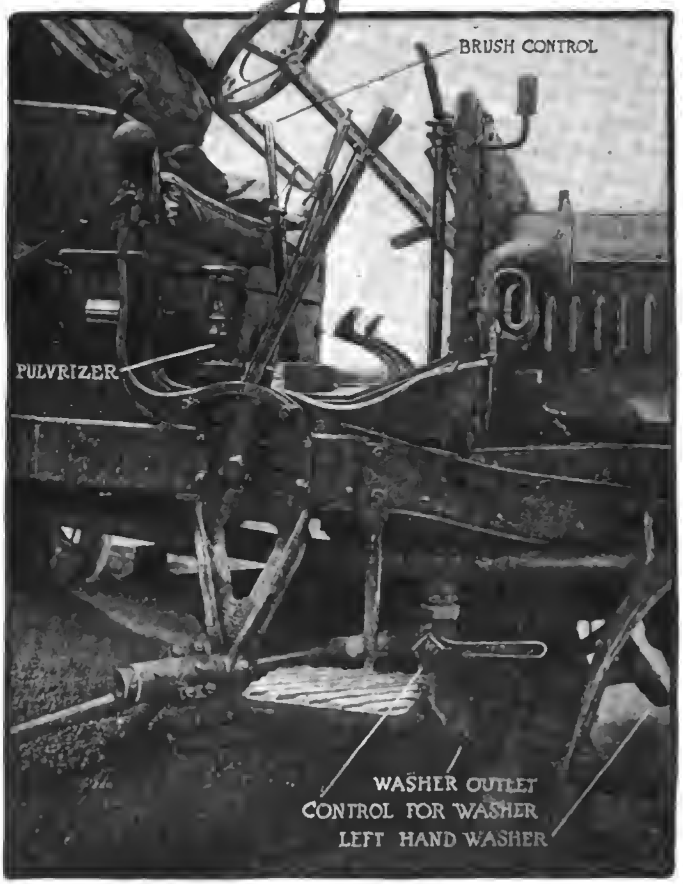
Street washing is generally undertaken during the early morning. The tank is filled from the street mains and the 570 gallons of water pumped out; with the pump working at full force the tank is emptied in about 10 minutes, during which time the machine is run at a speed of 7.5 miles an hour. After swilling with water it is customary to leave the street about an hour to allow the mud to soften before attempting to sweep. Another method is to flood the streets direct from the mains, then send the machines over later for sweeping only. This thorough washing only takes place from once to three times a week, according to weather conditions. It gives an absolutely clean surface with a single passage of the brush. Watering with the front sprinklers at full capacity, the tank is emptied in about 15 minutes, the machine during this time running at a speed of 7.5 miles an hour. This means that the machines will water over a width of 50 feet for a length of nearly 2 miles on one tank load of water.

The majority of the work, however, consists of street sweeping. This is done on a width of 67 inches, at a speed varying from 5 to 8 miles an hour, according to the condition of the road surface. Experience has shown that with a brush traveling at this speed a large amount of dust is raised in dry weather. To prevent this, each machine is fitted with a central sprinkler just ahead of the brush, thus slightly damping the street surface and effectively preventing the raising of dust. With only the pulverizer working, one filling of the tank is sufficient for 4 or 5 hours. During the 10 hours on the street, each machine covers a distance of 38 to 45 miles. This average is based on the work of the seven machines employed in the eighth ward.

One of the most important advantages of the motor sweeper over the horse variety is that owing to its increased speed it does not interrupt the normal flow of traffic. With an average of 3.8 to 4.5 miles an hour for a full day, including stoppages for filling tanks, etc., it is evident that the normal running speed must approximate 7 miles an hour. The maximum width of roadway watered at one operation is 50 feet. As



Upper—One of the rotary street sweepers in use in Paris. This is of the De Dion Bouton type. Lower—Partial side view of one of the motor-driven street sweepers, showing the driving mechanism of the rotary brush



Control features of one of the motor-driven street sweepers now in use on the streets of Paris and Versailles. The driver can operate all the important control levers from his seat and the minor adjustments sometimes necessary are all readily accessible

the ordinary Paris streets vary in width from 23 to 40 feet, they can all be covered at one operation. The boulevards and specially wide avenues, such as the Champs Elysees, require several operations.

For reasons of economy benzol is used exclusively in place of gasoline. Except in the matter of price, it has no advantages over gasoline; indeed, it is found to foul the motor a little and to necessitate pulling down at more frequent intervals. The average amount of fuel used is 46 gallons per machine per day; this works out at an average of 10.7 miles per gallon. These figures are taken on actual working conditions extending over several weeks, and not on a short experimental run under favorable conditions. Each brush lasts on an average 3 days, or a distance of 120 to 130 miles. At the end of this time it is so far worn down as to be of little use, and is then sent to the city brush factory for the bristles to be replaced.

According to the Paris municipal authorities, the economy by the use of motor street sweepers is from 12 to 14 per cent. over the same work done with horses. The authorities of the city of Versailles declare that an economy of 50 to 60 per cent. is obtained. Versailles has the advantage over Paris, however, of possessing exceptionally wide, straight avenues with very little traffic, thus allowing the machines to work constantly at their maximum efficiency. Paris is one of the most crowded cities in Europe, and except in the early morning the sweepers cannot work to their full capacity.

The De Dion Bouton sweeper and waterer is a machine with motor under a bonnet, the driver behind, and water tank on the rear platform. The brush is placed diagonally across the machine, between the two axles. The motor is an ordinary type of four-cylinder cast in pairs, the bore and stroke being 3.5 and 4.7 inches, and the nominal horsepower 18. Control is reduced to the operation of a throttle. So far as the drive is concerned, the machines follow the general De Dion Bouton design. There is a plate clutch, three-speed gearbox and transverse cardan shafts to the rear wheels. These latter are fitted with twin rubber tires, the front wheels having single rubber tires.

There are four main water outlets to be used according to the different classes of work to be undertaken. At the rear is a transverse sprayer through which the water flows by gravity on the opening of a cock. This is only made use of in narrow streets having insufficient width for the front sprayers to work to advantage. From the pump, at the extreme rear of the chassis, there is a left and right hand main feed pipe passing under the chassis and going to the circular section sprayers projecting beyond the front of the frame. On each feed pipe is a by-pass for the washers, these being branches from the main pipes with their extremity near the ground, just ahead of the brush, and fitted with a valve which can only be opened by the driver getting down from his seat. Also on one of the main feed pipes is a by-pass to the pulverizer, this being a fine spray nozzle near the ground.

The whole of the mechanism is carried on a sub-frame the full length of the main frame, and it is at the end of this sub-frame that the centrifugal water pump is mounted. The pump is driven by a propeller shaft having a sliding pinion on its forward end brought into engagement, by the use of a lever, with one of the gearset pinions. The operation is practically the same as changing gears. With the pump working, the operator withdraws either one or both of the piston valves at the inlet end of the two main delivery pipes. This delivers water to either left or right-hand pipes, or both. If street watering has to be done, the piston valves in the front sprinklers are withdrawn, either together or separately, admitting the flow to the sprayers. These sprayers are cylindrical housings having a series of fine holes on one-half of their circumference. On the outside of the cylindrical casing is a semi-circular guard which can be rapidly made to completely or partially cover the outlet holes. The two guards have separate

Klaxon Factory System Seen in Detail

Material and Labor Expense Recorded on Nine Forms—Standardization of Nomenclature and Labor Expenditure

AFTER having explained and described repeatedly in the past various systems used for recording materials and labor expended in the automobile service plants of diverse large firms, THE AUTOMOBILE proposes to describe below a simple yet efficient recording system of an up-to-date accessory manufacturing plant. Assuming that a plant of this nature has a yearly output retailing at a total of $1,000,000, it is obvious that every operation must be under the positive control of the management so as to make maximum economy possible. To illustrate this, suppose that by proper methods 25 cents may be saved on each article made by the company and that the output of the company is 20,000 pieces a year. The saving in this case would amount to $5,000. On the other hand, if the saving is possible, but is not realized, due to circumstances unavoidable or avoidable, the company may justly calculate that it loses $5,000 yearly which otherwise would go to pay dividends on its capital stock.

The system which will be taken up below is that of the Lovell-McConnell Mfg. Co., Newark, N. J., manufacturer of Klaxon, Klaxonet and Klaxet horns. Roughly speaking, the system and its various record forms may be divided into two parts, the recording of material and that of labor. There are five blanks for the handling of materials and for the recording of the cost of labor. It may be said in this connection that only productive material and labor are recorded by this system.

Use of the Job Order Blank

Suppose that a lot of 6,000 Klaxon horns is to be made within a specified time. The principal order for this purpose is issued from the main office over which the manager presides. For this principal order or job order, as it is called, the form, Fig. 1, is used. This is a wide sheet, 11.25 by 9 inches, printed black on white paper and punched along the left edge so as to fit into a binder. The office, when filling out this order, prepares one original and such carbon copies as are needed, one going to each factory department affected. The office fills out the form as follows: On the first line, marked Name of Appliance, is written: 6,000 Klaxons. The date on which the order was given, the order number, the names of the various parts and the quantity required of each, are also filled in. The Date Completed space allows for recording the date of the day on which the order is returned to the office complete. The office also names the materials for motor casings, armature laminations and windings, etc. This having been done, the job order and all its copies are sent to the stockroom. The Date Completed space allows for recording the date the order is returned to the office complete.

The stockroom foreman goes over the list, and in the space marked Amount in Stock he states the quantity of each kind of material stored at the plant. This information is entered on the original and on the copies of the job order; at the same time the materials which are in stock and usable for the job are tagged with a job number and put on a special rack, styled the reserve rack. Then all the sheets are sent back to the manager's office, and purchase orders are made out for the materials which are not in stock. At this time the carbon copies are distributed to the various departments, informing their foremen in advance of the work which they will have to have carried out during the next few weeks or months, as the case may be.

The purchase order which is sent out from the purchasing department to the dealer furnishing the company with a certain class of material or parts, is shown in Fig. 4. The blank

is 7.75 by 6 inches, and there are three copies of this blank filled out, each being printed on paper of a different color. One copy goes to the dealer, the other to the stockroom and the last to the office. In making out this order the purchasing department enters on it the name of the dealer who is to furnish the material, his address and how the goods are to be shipped. All the orders issued by the purchase department are numbered consecutively, the copies bearing, of course, the same number as their original. The number of the job for which the material is required and the date of desired delivery are also stated on this form. In a space between the two double rules the material is specified, and the treasurer of the company signs the order. When the latter has been acknowledged by the addressee, this is marked on the office copy and the same applies to a possible promise of delivery on the part of the dealer as well as the first and second follow-up letter.

Material Issued by Date

Received the above

Fig. 5—Material order from department to stockroom

When the material is delivered to the company it is checked by the stock clerk against the order and the invoice, and is tagged with the number of the job for which it is reserved; the invoice is sent to the office. Now, as the various departments require the materials they need to carry out their shares of the job, they call on the stockroom to issue the materials to them. For this purpose the foreman of each department fills out the order to the stock clerk, Fig. 5. This form is 8.5 by 5.5 inches and comes in pads being printed black on colored paper, a copy of different color paper being used for each department. The foreman of the department keeps a carbon copy of the blank as his own record. When the material has been delivered to the department employee by the stock clerk, the former signs the order as a receipt.

The requisition, Fig. 2, is used by the various department heads for miscellaneous materials required, such as specified drills, tools, etc. The blank used for this purpose and here shown is 7.75 by 4.5 inches. Upon the receipt of the requisition, the purchasing department either makes out a purchasing order for the material, or if it has been ordered already, sends out a follow-up letter.

In case the stockroom receives more material than was ordered this material is kept by the company and stored in the stockroom on the so-called free rack, which is opened for the use of any department. The clerk, however, who is in charge of the stock, uses wherever possible the material on the free rack for the job orders, as they come up, so that the free stock is kept down to as small as possible a quantity of materials.

Foundry Jobs on Special Order

When foundry work is required, the manager's office fills out the foundry order, Fig. 3, which is designed along similar lines as the form, Fig. 1. The sheet is 11.25 by 9 inches. The metal to be used is checked and the pattern number, number of pieces required, job number and foundry order number are entered on this sheet. The foundry foreman after having done his work records on the order the number of pieces made and their total weight after which the form is sent to the office and the material to the stockroom.

Coming to the labor recording system, the clock card and the daily time slip are the fundamental forms used. The former is a weekly record, and is illustrated in Fig. 9. The blank is 3.5 by 5.5 inches and besides spaces for the number and name of

Fig. 7—Wage receipt form blank

¶ The daily time slip, used to account for the portions of the total working time of each man, as given by his clock card, is designed to give every point of information relating to this phase of factory work, making an exact account thereof possible.

¶ By the use of the two forms shown above, the question of an exact payroll is being solved to mutual satisfaction of both the company and the force. These two forms, together with the weekly clock card, constitute an efficient time-checking system.

¶ The receipt for wages paid out to the worker is a fit example of how small trouble, which often is the cause of large nuisances, can be avoided. No worker having signed a slip such as this will come back and claim that he did not receive his pay.

the employee is marked for an entry of his total wages earned during the week and the deductions made for the sick benefit and the Klaxon Savings and Aid Association, a body organized for mutual assistance among the men. The clock card provides spaces for stamping three starting and stopping times a day on it.

As to the distribution of a man's working time, this information is obtained by means of the daily time slip, Fig. 6. This form comes in pads of 7.38 by 3.75 inches, being printed black on colored paper, a different color being used for each department for simplicity. Exact information including whether a man works on a time or piece basis is thus obtained and the slips of all the men are turned into the office at evening.

In this connection it should be mentioned that the company is making earnest and well-directed efforts toward a standardization of nomenclature of the various working operations carried on in the shop. The management recognizes that as long as different men style one operation as boring, drilling and whatever other names are used in the different shops, there is no way of getting away from misunderstandings in the company's office where the cost sheets are figured and made up.

Making Up The Daily Cost

In the office the information is transferred from the daily time slips to the daily cost sheet, Fig. 8, which is kept in a binder. This sheet is 8.75 by 11.5 inches, printed black with red and blue rules on white ledger paper. Of course as many cost sheets as necessary are used every day. Under Name, the exact part name is entered, and the job number is also written on the form. The lower portion of the latter is divided into eleven columns, each of which has three small divisions marked Date, Pieces and Cost. In filling out the daily cost sheet, the office clerk doing this work writes into the square space on top of a column the standardized name of the operation, for instance:

Casing, Drill and Tap.

Under this heading all the time spent by any worker of the factory in carrying out this operation on a job order during the day before is recorded, together with the number of pieces produced in that time and with the wage paid for that work. In this manner the full amount of any kind of part made in the shop is ascertained and this number must be identical with that of the pieces paid for on the previous operation. Any discrepancy arising causes an immediate examination of the situation to clear the problem. Likewise, this cost sheet makes possible the establishment of standards of cost for the production of any part or parts of the devices made by the company.

The day before pay-day each man receives a wage-receipt blank,

Fig. 8—Daily cost sheet giving the working operations of all men and their cost

Fig. 7, a yellow slip with black print, 4.5 by 2.5 inches. Before receiving his money, he signs the slip and exchanges it for his pay envelope.

In order to keep up a general discipline in the factory, the company has prepared a leaflet giving rules and regulations for its workers, Fig. 10. The same is 9.75 by 6 inches and gives complete instructions with regard to the work, payments and various points of order which must be rigidly adhered to. Each man receives a copy of this leaflet when starting in his position, and if he needs another copy, he may, of course, obtain the same from the office of the company.

Forms Adapted To Their Purpose

Close inspection of the various forms brings out their adaptability. For instance, the job order blank is so designed that the manager in his office, getting reports from the stockroom and the various factory departments, is able to have this information put on the job order original; the result is that this information is always at hand and it is not necessary to send for various department heads or clerks in order to find out things which, by proper communication, could have been forwarded to the manager's office days or weeks earlier. Likewise, it is possible at any moment to figure up the full cost of the whole job or part of it.

The daily cost sheet likewise opens up new perspectives. First of all it makes possible the standardization of cost of even the smallest of shop operations. Here is a practical and useful example of shop records. Cost standards having been arrived at, the time needed for the making of one unit part at average cost may be analyzed according to the rules of motion study and waste motions on the part of the workers may be eliminated. It goes without saying that once the nomenclature has been standardized this will also influence the design of the daily cost sheet. It will, of course, prove a saving of time if the various working operations are printed on cost sheets instead of being written.

Finally, the idea of the reserved stock rack and the free rack will commend itself to more than one factory manager.

Fig. 9—Workers' weekly clock card

¶ *This clock card for shop workers as used at the Klaxon plant contains a number of details comparing favorably with cards used in various other works and well worth consideration.*

THE following rules and regulations will govern employment in this factory.

TIME CARDS

Each individual is to ring his own time card when starting or stopping work. The payroll will be made up on the basis of the time as shown on the time cards. Deductions will be made on the basis of quarter hours. One minute's tardiness is sufficient to cause the loss of one quarter hour's time.

WORKING TIME

Hours of employment are from 7.00 A. M. to 12.00 M., and 12.30 P. M. to 5.30 P. M. on week days, except Saturdays. On Saturdays from 7.00 A. M. to 1.00 P. M. On Saturdays the power will shut down at 12.45 P. M. to give machine operators an opportunity to clean their machines. Employees who do not run machines are to continue working till 1.00 P. M.

DAILY TIME SLIPS

Daily time slips are to be made out the first thing each morning for the previous day's work. They must be on the foreman's desk not later than eight o'clock.

PAY DAY

Pay day is Wednesday, and payment will be made for the week ending on the previous Saturday. If Wednesday is a holiday, payment will be made on the previous day.

OVERTIME

For overtime till midnight payment will be made at the rate of time and a quarter. After midnight and for Sunday and holiday work at the rate of time and a half.

SMOKING

Smoking is positively prohibited in the factory at all times. It is permitted during noon hour in the foundry, boiler house or yard.

WASH-ROOM PRIVILEGES

Employees must keep all clothing in the wash-room. The wash-room will be kept locked and entrance to the same during working hours can only be gained by presenting a permit duly signed by your foreman.

OILY WASTE

Oily waste must not be left laying around, but is to be put in the receptacles provided for it.

GENERAL CLEANLINESS

This company makes a special effort to provide its employees with comfortable surroundings and the coöperation of our employees is requested, in order that the best results may be obtained.

You are particularly requested to throw refuse of all kinds into the dirt barrels and not on the floors or grounds.

You are also cautioned not to leave towels, hats, shoes, etc., laying around the wash-room. It is understood by the cleaners that material left laying around is worthless and can be removed when found.

TOOLS

Tools will be issued from tool room only on a check. In the event of an employee leaving, all tools must be returned before an employee will be paid off.

Failure to obey any of the above will be considered sufficient cause for summary discharge.

Lovell-McConnell Mfg Company
Newark, N. J.

Fig. 10—Copy of company's rules-and-regulation leaflet distributed to workers

Choosing a Color Scheme

Lighter Shade Should Be Used on the Chassis Than on the Body in a One-Color Scheme

IN choosing a one-color scheme for the car, it is always in order to use a lighter shade for the chassis than is employed upon the body. A better-balanced appearance will invariably result. When, for example, a deep ultramarine blue is selected for the panels of the car, with the upper parts of the body black, the chassis should carry the light shade of ultramarine blue. Stripe the chassis with a 1-4-inch line of black and at each edge of this stripe run a fine line of gold. Stripe the dark blue panels with two 1-8-inch lines of the light shade of ultramarine blue and run a fine line of gold between the two. This yields a charming color effect.

Another method of using blues on the car consists of deep blue for the door and main side panels, and a medium deep shade of the same blue for the chassis and upper panels of the car. Paint the moldings black and stripe the chassis with a broad black line split at the center with a single line of gold.

In greens, Brunswick green, deep, for the main body panels, with black upper panels, and black moldings, with double fine lines of black run around the green panels makes an ideal combination. The chassis should be painted the light shade of Brunswick green with striping lines of black.

Silk Green Is Very Popular

Silk green is probably the most popular green for this season among owners attracted by smart coloring. Use for example, medium silk green for the body panels, dark shade of same color for the narrow upper panels, and light shade for the chassis.

Stripe the body panels with double lines, 1-8-inch wide, of black, with a fine line of gold running between the two. Stripe chassis with fine lines of black 1-2 inch apart and in this center space cast two fine lines of gold 1-16 inch apart. Have the upholstery to match the body panels, and the effect will prove admirable.

Napier and thistle green are soft toned, magnificent greens, and upon the heavier type of car they offer splendid effects. Paint the main body panels in either of these two greens and for unique effects run vertical 1-inch stripes 1-5 inch apart, of darker green, or if so preferred, of lighter green, directly across the panels. Paint the upper panels either black or a very deep shade of the main panel green. Paint all moldings black. Give the chassis a light shade of the same green, and stripe with the deep panel green.

The main scheme of coloring for the automobile at the present time consists of colors in the main dark and fine without any sharply contrasting color such as the reds or maroons or lakes might afford.

Dark warm browns for touring cars and runabouts are much in evidence this season, and they really do produce fetching effects when artistically placed upon the surface. Place the dark shade of tan brown on the upper or narrow body panels, the medium shade of same color on the main body panels, and light shade for the chassis. Thus you have a graduated color scheme which brings the shades into proper relation to each other. Paint all body moldings black and use for the panels and for the chassis .375-inch lines of black, edged with very fine lines of gold. Quite the same scheme may be effectively employed in using Manila or Oriental browns, two exceedingly popular browns.

For a particularly high-colored blue withal strikingly bold and beautiful, adapted for the light runabout and a light class of touring cars, cobalt blue, light, for the main body panels, with moldings black, and cobalt blue, extra light, for the chassis, with gold or aluminum striping, done principally in fine lines, yields something in the way of colors quite out of the ordinary.

A new comer in the field of lake pigments is the lovely Japanese crimson lake over which the ladies in autodom linger in genuine feminine adoration. This is a wonderfully deep, luminous pigment suitable for big touring car decoration. A very effective way of painting the car in this color is to use the deep shade for the main body panels, the light shade for the upper panels and the chassis, and to paint the moldings black, and employ black lines for the striping. Fine lines of gold look attractive upon this color.

The fact that the lake pigments are rapidly increasing in favor for use upon the automobile, and especially for touring cars, serves to interest the car owner in these colors as never before.

To develop striking, yet harmonious combinations with the lakes, paint the main panels of the car English scarlet lake, deep, upper panels English purple lake, chassis English crimson lake. All moldings to be painted black. Again, paint the upper panels black, large panels Munich lake, medium shade, and chassis French carmine, moldings to be painted black, with black lines of striping.

Another way consists of painting the main panels English scarlet lake, upper panels French carmine with chassis same color. Moldings to be painted English purple lake. Striping lines on both body and chassis to be in black and gold lines.

Another very popular combination is made by painting the large body panels English purple lake, upper panels and chassis English crimson lake, moldings black. Lines of striping to be in aluminum.

Returning to the green pigments, one of the superb greens of the season is olive green, a shade instantly attractive. This is a soft, warm, brilliantly toned green. Give upper panels plain black, large panels deep shade of the green, and chassis a light shade of same color. Moldings to be in black, and striping lines to be French carmine.

English rose lake of deepest shade for the upper panels, medium shade for the large central and back panels, and the lightest shade for the chassis, the lines of striping to be in French black; moldings painted in same color.

All these lakes are very largely transparent, and to be effective, they must be used over ground colors brought up with great care and enriched to an extent only surpassed by the actual lake coat itself. Over such grounds it is good practice to apply a single coat of the selected lake mixed to dry and flatten out without any gloss. Then for the final coat thin some of the lake with turpentine in which condition add sufficient rubbing varnish to give the mass a good, substantial gloss. Handled in this manner there is developed a color display which for elegance and luxurious effects cannot be surpassed.

All colors will appear richer and finer if they are used in connection with varnish, as varnish colors, for the final color developing coat. If the surface is brought up clean and smooth, with the feel of velvet, and given one or two coats of the color diluted with turpentine to dry flat without luster, the final color coat will need to carry only sufficient pigment to stain the varnish.

Color Combinations for Big Cars

Dark and medium cobalt blue, dark shade for the body and medium share for the chassis, both being striped with double fine lines of white or gold, also give a rich and durable effect.

In brown, the tan color, dark shade for the body and light shade for the chassis, striped with a .375-inch line of black edged with fine lines of gold form an excellent combination.

In the gray, battleship and monitor gray are perhaps the most widely liked. If brought up carefully to a finish they are among the exceedingly durable colors. They make exceptionally pleasing colors for big cars.

For a seven-passenger touring car, French gray, deep shade for body and medium shade for chassis, striped with a .25-inch line of light French gray and this line edged with fine lines of gold, gives great service and a very attractive appearance.

Among the New Books

Numerous Works Treating of the Automobile and Kindred Subjects of Interest Are Spring Offerings

ALTHOUGH some of the books reviewed herewith would seem at first glance to be foreign in subject matter to the automobile and consequently to many of our readers, a further inspection brings out the fact that all of the works considered are in some way related to either the car itself, its accessories or to some phase of the wonderful industry which has been built up around it.

List of Automobiles Showing Model Type of Body and List Price with Horsepower and Collision Insurance Ratings, published by the Commercial Union Assurance Co., Ltd., of London. 55 John street, New York. Issued to interested parties by the Commercial Union Assurance Co., Ltd.

This little handbook contains the names, models, horsepower and collision classification of practically every motor-driven vehicle. This book used in connection with the rate sheet will immediately tell anyone the amount of insurance required on any given vehicle.

The Gas, Petrol and Oil Engine, Vol. II by Dugald Clerk and G. A. Burls, members of council of the Institution of Automobile Engineers, published by John Wiley & Sons, New York City. 838, 5.5 by 8.75-inch pages, with 478 illustrations. Cloth, $7.50.

Three years have been spent in the preparation of this volume, and this length of time has elapsed since the first volume was published. In the present book there are twelve chapters. Chapters 1, 2, 5 and 12 are by Dugald Clerk, chapters 7, 8, 9 and 11 are by G. A. Burls. The remaining chapters were written in collaboration. The work has been arranged in such a manner that it represents the views of both authors in combination, each subject touched upon having been dwelt upon in a joint discussion.

Chapters 1 and 2 treat of the development of two- and four-cycle motors and describe the problems which have come up in design and how they have been solved or unsolved as the case may be. Chapter 3 deals with the development of the ignition system; chapter 4 describes governors; chapter 5 touches upon gaseous fuels; chapter 6 deals with the volatile fuels; chapters 7 and 8 take up the design of former and existing types of gasoline engines; chapter 9 is devoted to carburetion; chapters 10 and 11 discuss oil engines and chapter 12 is devoted to the future of internal combustion motors.

The chapters are all exhaustive on the particular subject to which they are devoted and the entire work is of value as a reference book.

Automobiltechnisches Handbuch, 7th edition, illustrated; by Dr. Ernst Valentin, with assistance of ten other engineers; 952 pages. Published by M. Krayn, Berlin W 57. Price, 4.50 Mark.

This work, in its edition for 1913, enters upon nearly all those questions related to automobile construction and engineering—including motorboats and motorcycles—which are omitted, for being too specific, from the general engineering handbooks. It contains opinions as well as data; in most cases well separated, however. A table of logarithms and a recapitulation of mathematics and physics, sufficient for those who are only rusty but not for learners, add to its practical value. The illustrations are drawn from textbooks and from material furnished by the German industry. Current topics, such as valveless motors, silent chains and gears, worm drive, are included in the treatment. The print and the illustrations are too small for comfort and clearness, and for this the low price can compensate only in part. For engineers and mechanics in this country, the book may in many instances have a special value as a means for keeping abreast of German technical nomenclature, as in most instances it is handier and more definite and conclusive in this respect than a dictionary, though of course not so complete. The chapters on traffic and legislation should be of interest to all touring in Germany.

The Autocar Imperial Year Book, 1913, for circulation in the colonies over seas and abroad, published annually by Iliffe & Sons, Ltd., London, Eng., 112, 12 by 8-inch pages, illustrated. Boards, 2 shillings, 6 pence.

This work is a review of the automobile situation of the world in general and England in particular as it stood at the beginning of the year. The trend of modern development is studied by taking up particular parts of the car and pointing out what has been done during the year of 1912. Not only the engine, but the details of coach work are touched upon and the development pointed out. A complete data table covering 20 pages is given in which are included all the important details of the best-known cars in the world which are on the British market. An interesting department of the issue is the history and the records of Brookline track. A study of the lighting systems and starters now on the market is also of special interest. This work can be read to advantage by any member of the trade or anyone else who wishes to keep in touch with the British industry.

The A. B. C. Fiscal Handbook, published by Free Trade Union, 25 Victoria street, London, S. W. 262 pages 5.5 by 8.5 inches. Paper, 1 shilling.

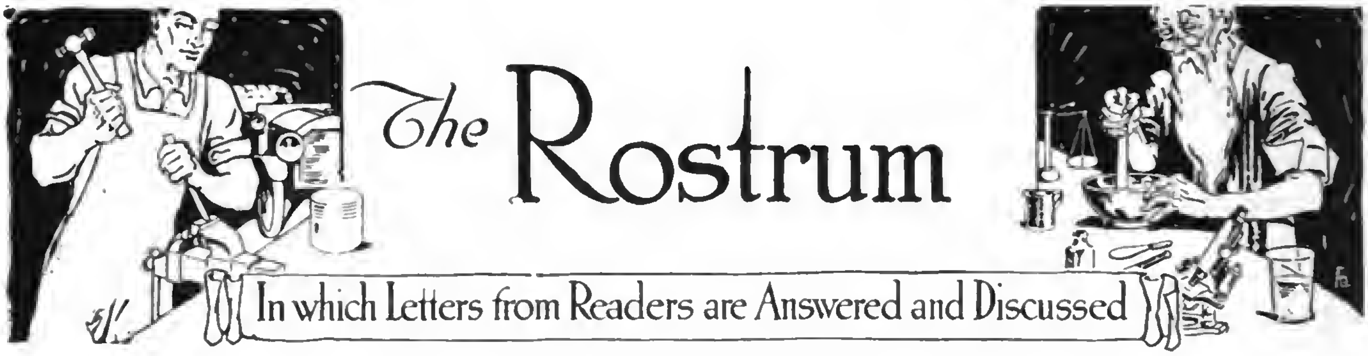
The Fiscal Handbook, 1913, contains complete statistics of British foreign trade over a period of years. These statistics are based on the declarations of importers and exporters of the goods under their respective classifications as verified by the customs officials at the various British ports. The figures on exports are automatically checked because the exporter must declare specifically whether the goods imported are of foreign or British manufacture and in case of a mis-statement is liable to penalization. As for imports, the value of all goods arriving in England and declared as mentioned are included in the import figures under their various classifications, except personal luggage, ships and military stores, packing cases and a large portion of the jewelry imported. Many interesting facts may be learned from the Handbook. Of particular interest to the automobile world, however, are the figures on automobiles, parts and chassis given on pages 150 and 151.

Trade Mark Laws of the World and Unfair Trade. By B. Singer, published by the author, 30 Church street, New York, or National Life Bldg., Chicago. 700, 6 by 9-inch pages, bound in buckram, $5.

This work gives a digest of the trade mark laws of every country of the world. The registration of trade marks of popular and standard classes of merchandise has become tremendously important of late years, owing to the keen rivalry among the nations of the world. A registered mark protects the manufacturer as well as the owner against those who seek to imitate the production of a certain article. Trade mark laws of different countries vary to such an extent that it is necessary to anyone engaged in international commerce or who markets an article which he desires to protect against foreign imitators.

An Expensive Experiment. By Reginald Pelham Bolton, author of *Building for Profit, Motive Powers*, etc., published by the Baker & Taylor Co., New York City. 281, 5 by 8-inch pages. Cloth, $1.25.

This is the story of a wasteful method of securing power which was adopted by a Canadian province, in utilizing the Canadian Niagara. "In 1897," states the author, "the city council of Toronto applied to the legislature of Ontario for permission to enter upon municipal ownership and operation for electrical service." The result of this was what the author calls the Great Experiment. How this experiment worked out and its result in the loss to the public is interestingly told by the author in a clear, concise manner.



Ignition Used on the 1911 Ohio—Detecting Acetylene Leaks—Securing Proper Valve Timing—New Jersey Law in Effect—Ford Lights Do No Damage—Proper Adjustment of Ford Vibrator—Trouble Caused by Dirt in Gasoline

Splitdorf Ignition on Ohio 1911

EDITOR THE AUTOMOBILE:—Will you kindly explain the Splitdorf ignition system as used on the 1911 Ohio 40?

St. Louis, Mo. E. H. K.

—On the 1911 Ohio cars the model B and model D Splitdorf magnetos were used. These magnetos are absolutely the same except that the model B has three permanent magnets and the model D has two. These are low-tension magnetos. That is to say, the armature of the magneto has but one winding and the current is raised to a high voltage by passing it through a transformer having a low and high-tension winding similar to that of an induction coil for batteries. This brings the current to a point at which the tension is sufficient to cause the spark to jump across the gaps in the plugs against the resistance of the gas compressed in the cylinders.

In addition to using the current from the magneto the transformer also acts as a spark coil by using the breaker mechanism of the magneto as a circuit breaker to interrupt the battery current. The battery current is used for starting purposes or for an emergency. The distributor is used to bring the current thus used to the spark-plugs. This gives a dual system with one set of plugs and both systems are controlled by a switch on the dash.

In Fig. 2 a full wiring diagram is given for the models B and D magnetos. By arranging the wiring in the manner shown in this diagram the system above described is operated.

With a system of this kind you have always a reserve in case the magneto should ever get out of order. The batteries would not be disabled through any disarrangement that could possibly occur under ordinary circumstances.

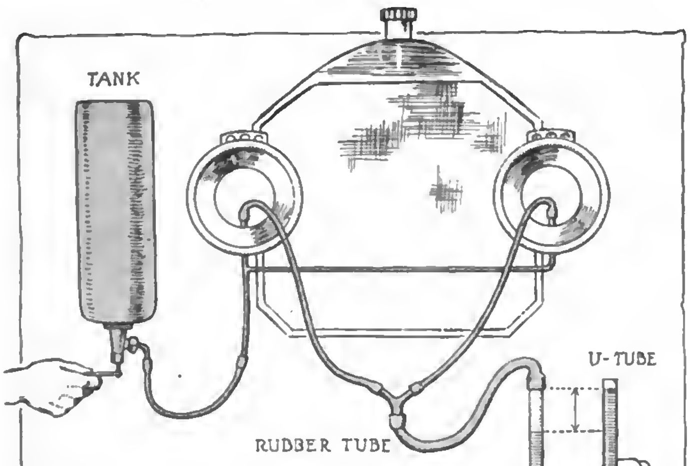


Fig. 1—Apparatus used for detecting the existence of a leak in the acetylene line

Locating Acetylene Gas Leak

Editor THE AUTOMOBILE:—I have been troubled by the gas tank on my car running down without using the lamps. I think there is a leak somewhere in the line but I have been unable to find it. I would like to find out two things, first if there is a leak and second how to locate it. I am not positive about there being a leak as it might be that I have used the lamps more than I think and that I am mistaken in my calculation as to how long I have had them lit, but if there is a leak I want to find it. I know acetylene is traceable by an odor but I have not been able to smell any escaping gas along the pipes. What method do they use in garages for determining whether or not there is a leak?

German Valley, N. J. GAS-LINE.

—You can readily determine whether or not there is a leak by using the simple apparatus shown in Fig. 1. This consists of three pieces of rubber tubing, a three-way pipe connection, and a glass U-tube. The burners of the acetylene lights are removed and the ends of the rubber tube placed over the projecting pipe as shown in the illustration. The valve on the gas tank should be closed while this is done. Some water is now placed in the U-tube but not enough to completely fill it. The needle valve on the gas tank is slowly opened until the water in the U-tube is lifted to the position shown in Fig. 1. The valve is then closed and the U-tube watched. If water drops to the same level in both branches there is a leak. The leak can be found by mixing up a thick soapsud solution and covering sections of the pipes and tubing especially at the joints. The leak will be detected by the bubbles.

Timing Intake and Exhaust Valves

Editor THE AUTOMOBILE:—In timing the exhaust valves and intake valves by means of a rod put in priming cups, where should the exhaust close and intake open; giving it in inches or part of an inch of the stroke? Also the difference in a 4-inch stroke, 4.5-inch stroke and 5-inch stroke; or, are they timed alike? Are the firing points the same on the battery as magneto in setting? What is the correct firing position for the piston on a 4-inch stroke, 5-inch stroke and 5.5-inch stroke?

Newark, N. J. JOHN WILLS.

—It is impossible to do a good job in timing the valves of a car by measuring with a rod in the way you suggest because the measurements are so small at the beginning and end of the stroke as compared to a number of degrees of revolution of the crankshaft. The timing should be done by measuring the degrees on the flywheel. It is easy to divide the circumference of the flywheel into 360 equal parts and to lay out the timing as accurately as desired instead of relying on micrometer measurements in thousandths of an inch when measuring by means of a rod. For instance, 5 degrees past upper dead center on a

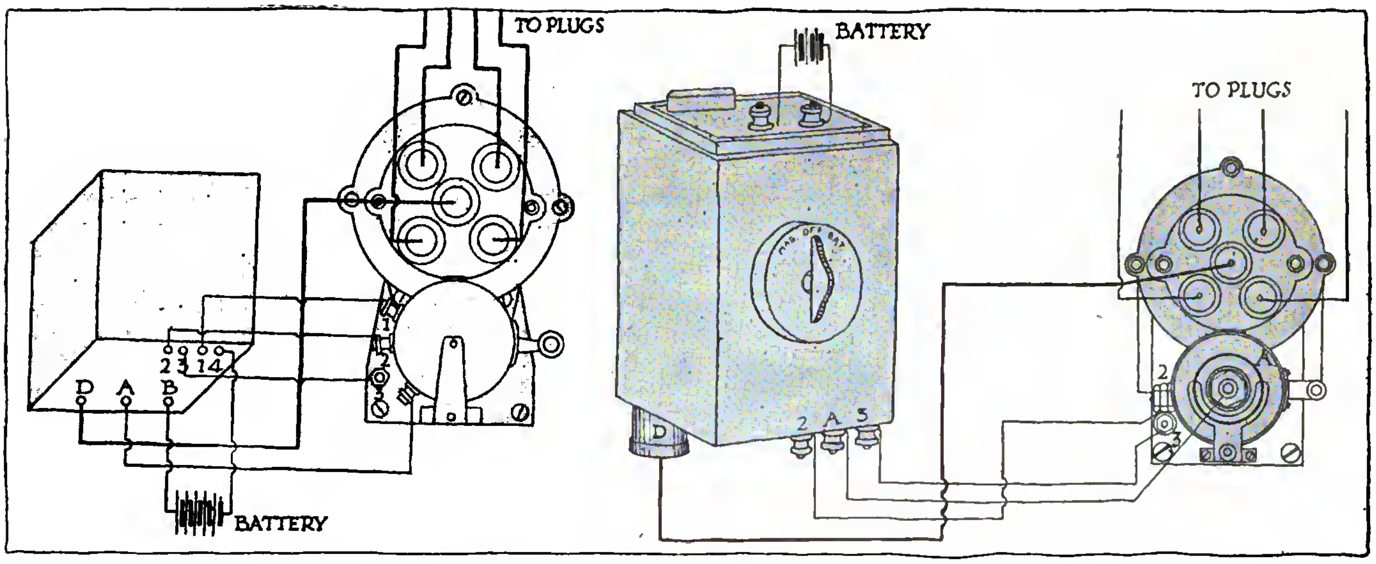

Fig. 2—Method of wiring model B Splitdorf magneto and model D Splitdorf as used on the Ohio 1911

12-inch flywheel would mean that the piston had gone down on its stroke a distance of .0457 inch. This would be rather hard to measure correctly. This same distance measured around the circumference of the flywheel would be .5236 inch. This is more than ten times what you would have to measure on the rod through the cylinder and therefore gives you about ten times the chance of being accurate. It is much easier to measure .52 inch than it is .04 inch in the first place and a difference of .01 inch in the case of the .52 would not be serious while with the .04 inch it would be a 25 per cent. error and would be serious. The idea of measuring timing in the way you suggest should be abandoned.

Open the compression cocks on the motor and turn it over until cylinder No. 1 is on the exhaust stroke. Revolve the motor slowly, then until the piston in this cylinder reaches upper dead center. This you can tell by means of the rod in the compression cup hole. Mark the rod at the point where the piston is at upper dead center or, in other words, when the rod is lifted as high as possible. When you have got this point located exactly and you are sure that you are right, center-punch the flywheel and some mark on a part of the stationary part of the engine near it so that you will know that when these two marks are directly opposite each other the piston in the No. 1 cylinder is on upper dead center. After you are sure the marks are in line correctly and that the piston is really on upper dead center, center punch on the flywheel alongside the mark you have made, 1-U-C. This will signify that cylinder No. 1 is on upper dead center.

You have now made a definite point from which you can start your timing operations. Before you can do anything else you will have to know what part of the circumference corresponds to 1 degree, because in this kind of measuring work dimensions are given in degrees and not inches. A degree is 1-360 of the distance around the flywheel. If you have a 12-inch flywheel each degree is .1047 inch; on a 14-inch wheel each degree is .12508 inch. This is practically 1-8 inch.

The cams being made for your car you will have to arrange the opening and allow the closing of the valves to fall as it will. Turn the motor over slowly until the flywheel has turned 10 degrees. This will be 1.047 or 1 3-64 inches on a 12-inch wheel or 1.2508 or 1 1-4 inches on a 14-inch wheel. At this point the inlet valve on No. 1 cylinder should start to open. At this point put another mark on the flywheel opposite the mark which was opposite the 1-U-C mark that will now be 10 degrees around to the right as you face the motor. This mark shows where the inlet valve on cylinder No. 1 starts to open and should be marked I-O-1.

The next point to locate is the opening of the exhaust valve on the No. 1 cylinder. Turn the crank slowly around to the right on the suction stroke, while the inlet valve will remain open and then around on the compression stroke and down on the firing stroke until you reach a point 40 degrees in advance of lower dead center. At this point the exhaust valve should start to open. If you have an L-head motor the cams will be on one shaft and when you have set the first one you will have no control over the others, but will have to let them fall as they come. With a T-head motor, however, you can set the exhaust valve in the No. 1 cylinder. On a 12-inch wheel 40 degrees will be 4.188 inches, or 4 3-16 inches, and on a 14-inch wheel it will be 5.032, or 5 1-32, inches. This distance is measured around the circumference as described. The point on the flywheel that falls opposite the mark on the fixed part of the motor should be labeled E-C-1.

The inlet valve should close 30 degrees after lower center and the exhaust valve should close 5 degrees after upper dead center. These points should be marked on the flywheel the same as the others and also the timing of the other cylinder. For instance, where the exhaust valve of No. 3 cylinder closes the mark used would be E-C-3.

The timing on the different motors you mention will all be the same when referred to the degree system and you will not have to bother with the differences in stroke as these are automatically taken care of. In each case the maximum firing point advance should be 37.75 degrees before dead center, or 6 7-32 inches on the flywheel.

Jersey Law Requires License

Editor THE AUTOMOBILE:—1—Could a boy of fifteen under any circumstances in New York and New Jersey procure a driver's, owner's or chauffeur's license? I can pass any examination that could be put to me. Another question as to whether a boy can drive if accompanied by his father (the owner)?

2—I would also like to know what compression is generally used on special racing cars; also the piston clearance and the amount of clearance at top and bottom of stroke, *i. e.*, amount of taper in cylinder.

New York, N. Y. FRED H. WELLS.

—1—The law in New Jersey as now in force on this subject is as follows:

The Commissioner of Motor Vehicles shall be authorized, and full power and authority are hereby given to him to license at his discretion and upon payment of the lawful fee, any proper person of the age of 18 years or over to be a motor vehicle driver, said commissioner or his agent having first examined said person and being satisfied of his ability as an operator, which examination shall include a test of the knowledge on

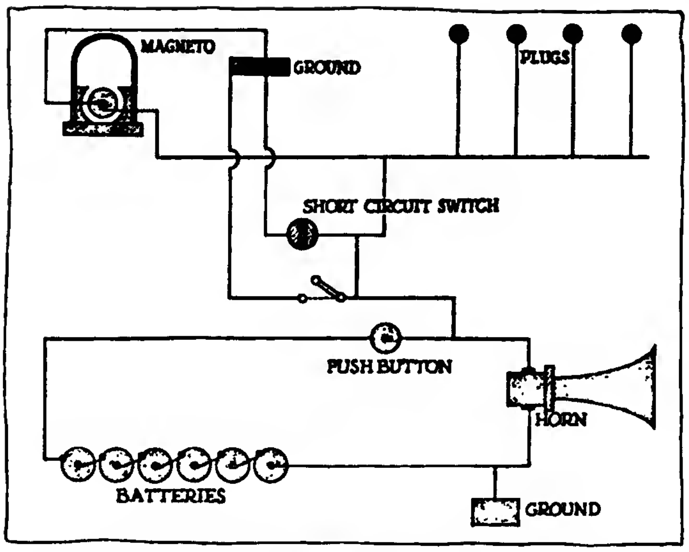

Fig. 3—Incorrect methods suggested by reader for throwing horn and magneto out of circuit

the part of the said person of such portions of the mechanism of motor vehicles as is necessary in order to insure the safe operation of a vehicle of the kind or kinds indicated by the applicant, and the said applicant having demonstrated his ability to operate a vehicle of the class designated; provided, that it shall be lawful for the Commissioner of Motor Vehicles to grant licenses to persons between the ages of 16 and 18 years who, by reason of their exceptional ability, the Commissioner deems proper to be licensed, such persons to be licensed only by the Commissioner after a personal examination held under his immediate supervision; and the said Commissioner of Motor Vehicles may, in his discretion, refuse to grant a license to drive motor vehicles to any person who shall, in the estimation of said Commissioner, be an improper person to be granted such a license; and the said Commissioner shall have power to grant a registration certificate to the owner of any motor vehicle, application for registration having properly been made and the fee therefor paid, and the vehicle being of a type that complies with the requirements of this act. But it shall be lawful for the Commissioner of Motor Vehicles to refuse registration to any vehicle that, in his estimation, is not a proper vehicle to be used upon public roads and highways of this State.

2—The compression pressure on racing cars averages about 80 pounds to the square inch. The piston clearance on these cars varies with the bore of the car but is very close to .010 inch at the top, about .005 inch at the bottom and .008 inch at the rings for a 4.5-inch engine.

Ford Vibrator Not Adjusted Right

Editor The Automobile:—I have a Ford touring car model T 1910. It has not been run over 5000 miles and has just been taken down to see what caused a knock. We found the magneto was touching thirteen of the fields, due to slight endwise motion in the main bearings. I had new bearings put in at the garage, but the motor will not run on the magneto, except for a little while running idle. It then stops and will not start on magneto. The magneto will light a 6-volt lamp. In fact, it will make the carbon glow slightly when spinning by hand. Is there anything the matter with this magneto? Have the repair men assembled the motor with too much clearance between magneto and fields? What is the proper distance of this clearance? Why does the magneto light up a lamp and the motor will not start or run on it? The garage man says magneto is no good; if so, why does it generate from 4 to 6 volts.

Athol, Mass. George T. Brills.

—The fact that the magneto will light a 6-volt lamp shows that it is in good condition. The trouble is not in the magneto at all but in the vibrators. These are not adjusted correctly and should be attended to. The correct clearance is 1-54 or .018 inch.

Lights Detract from Power

Editor The Automobile:—I am the owner of a Ford T 1912 Roadster which I am equipping with electric lights to be run from the magneto. What voltage and candle power lamps would you advise me to use? Will lights of this kind injure the magneto in any way? Does the 1913 magneto produce any more current than the 1912 or is it just about the same?

Modesto, Ill. K. L. Nifong.

—The lamps to be used in connection with a system for the Ford car should be of the 6-volt type and develop about 10 candlepower. The use of these lamps will not injure the car or the magneto in any way but will have the effect of reducing the power while the lamps are in use, because the spark given by the magneto will be weaker. When the lamps are taken out of the circuit the power will be just as good as before. It is merely a matter of whether or not you desire to sacrifice a small amount of power for the use of the lamps. The 1913 magneto does not produce any more current than did the 1912. They are the same.

Dirty Gas Line Causes Trouble

Editor The Automobile:—1—What might be the trouble with a motor of the four-cycle type which runs nicely when at a moderate speed idle, but which stalls as soon as the throttle is opened and the load put on it? Sometimes opening the throttle has the same effect as cutting the ignition. Then as the throttle is closed to its former adjustment the engine resumes its smooth even running. But if the throttle is very slowly opened up it will attain to a high speed and if kept racing by slipping the clutch the car may be hauled for quite a distance. At other times it pulls very nicely. I have been unable to find any trace of this trouble.

2—What is the advantage of wrapping leaf springs with tape? I have frequently noticed the springs of racing and test cars so bound. Would it be any material help on a car in ordinary service?

3—Have sleeve valve motors of the Knight type been used to any extent in racing? Will this motor not heat more readily than the poppet valve type on account of two additional walls between the combustion gases and the water?

Bridgeville, Pa. L. J. Bowman.

—1—Dirt in the carbureter or in the gasoline can be the cause of trouble which is of a particularly mystifying nature.

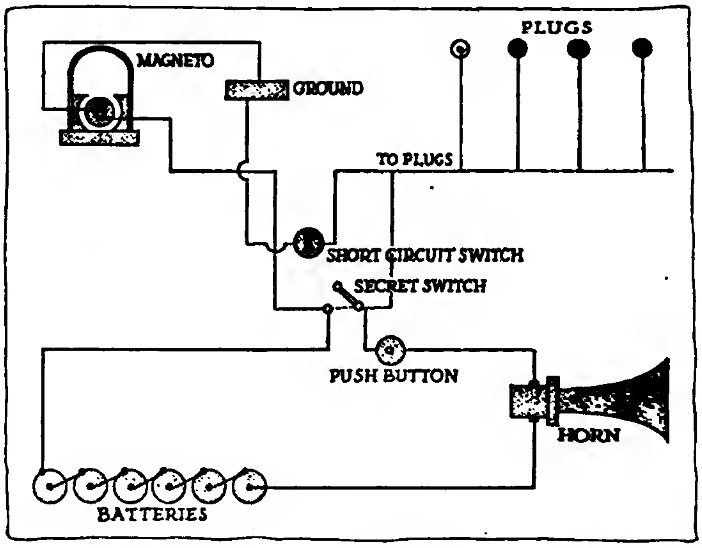

Fig. 4—This method of wiring would cause magneto to deliver current through batteries and horn. It is incorrect

The gas enters the float chamber of the carbureter very slowly and the result is that if there is a sudden demand for an extra supply of fuel such as would be the case where the throttle is opened quickly or the motor is called upon to pull against a stiff grade, the result is that there is not enough fuel to meet the demand and the motor dies. You have no doubt noticed that if you close the throttle for a short time while the car is running along and then open it again the motor will start all right and run for a short time before it stops again. The best way to remedy the trouble would be to take off the carbureter and clean it out. This can be done very nicely by compressed air if you are anywhere near a garage where they maintain pressure. The gasoline should be drained from the tank and the air shot through the gasoline feed pipe. To save future trouble in this respect always strain the gasoline through chamois. The garage man often protests against this, stating that there is a strainer in his line, but to be on the safe side it is better to use the chamois.

2—Springs are wrapped with tape to render them stiffer. On racing cars and on cars that are run over the roads at high speed on test work it is not desirable to have the more delicate spring action that is required in a car used for pleasure. In fact, such a suspension would be detrimental, as may readily be seen, because where the car is not slowing down for any bumps in the road, with a sensitive suspension the car would be jumping all over the road. Where shock absorbers of the friction type are used the friction member is drawn up much stiffer. It would not be of any use to a car in ordinary service unless you desire to go at high speed over country roads.

3—The Knight-equipped cars have figured prominently in many of the races held in Europe. In the last Belgium Grand Prix race a Knight car scored a victory. The results of that race were as follows:

Car	Bore and Stroke	Cyl. area		Speed imposed	
Minerva (Knight motor)......	3.1 x 4.8	3	liters	40	m.p.h.
Hermes	2.8 x 4.7	2	"	35	"
Mercedes (Knight motor)	3.9 x 5.5	4.4	"	44.4	"
Opal	2.7 x 5.1	2.1	"	35.3	"
Lion-Peugeot	3' x 6.1	3	"	40	"
Schneider	3.2 x 5.5	3	"	40	"
German (valvelesa)	3.6 x 5.9	4	"	43	"
Sava	3.2 x 5.5	3	"	40	"
F. A. B.	2.9 x 4.7	2.2	"	35.5	"
Miesse	3.5 x 5.5	3.6	"	42	"
Ford	3.7 x 4	2.9	"	39.9	"

Knight motors do not show any tendency to heat up if the lubrication is properly attended to.

Installing Secret Control Switch

Editor THE AUTOMOBILE:—As I have been perpetually bothered by small boys who take a fiendish delight in hearing my electric horn and who are not adverse to running down the horn batteries, I intend installing a small switch that will throw the horn out of circuit when I leave the car.

I live in New York City and often use the car in a business way, leaving the car outside my office building for perhaps 2 or 3 hours at a time. During this time I am generally undergoing quite a strain on my nerves because I worry for fear some one with a love of automobiling and a small conscience may make off with the car. I worry, in fact, so much over whether the car will or will not disappear that I cannot keep my mind on my work while the car is standing outside. I intend to fit a small switch that will take care of this also.

It struck me that it would be a good scheme to combine the two switches into one so that I will merely have to throw the secret switch when leaving the car and the horn will be out of circuit and the magneto short-circuited at the same time. To do this requires a little fancy wiring and I have thought out two schemes, Figs. 3 and 4, which I submit for your consideration. Are both of these correct or if only one of them which is correct and why?

New York City. GOTHAMITE.

—Both the methods that you suggest are wrong as may be seen if you will trace through the wiring diagrams. Taking first, that shown in Fig. 3, you will notice that the magneto is per-

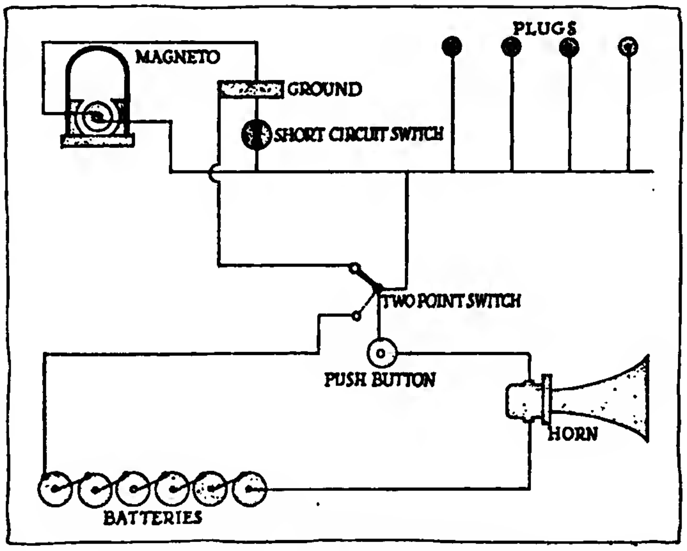

Fig. 5—Correct method for installing secret switch of two-point type to throw horn and magneto out

petually short-circuited through the horn. The current would run from the magneto through the horn and then back to the magneto through the ground. As long as the magneto is grounded you should not ground any other circuit that can in any way communicate with the magneto because if you do the magneto will surely be short-circuited and you would not be able to get a spark at the plugs. In fact the magneto would probably blow out the windings of the horn if you should spin the motor while connected up in this manner.

The plan that you outline in Fig. 4 is also bad. You will notice that the horn batteries and the horn close the circuit which you intend to break by means of the switch. The high-tension current would pass through the batteries and the horn and then to the plugs, closing the circuit. If the car was running on the magneto and you intended to stop by opening the switch which breaks the magneto circuit, or rather which is supposed to, the magneto would be forced to send the current through the batteries and the horn. This would probably burn out the horn.

The correct plan is that shown in Fig. 5. As you may see a two-point switch is used. This is no more complicated than a one-point as it can be of the type that is either in one circuit or the other. When one circuit is closed the horn is in circuit and so is the magneto. When the switch is thrown over the magneto is short-circuited and the horn circuit is broken.

Lamp Dimensions and Candle Power

Editor THE AUTOMOBILE:—Would you please give me the voltage, amperes required and candlepower of a set of standard Edison base passenger-car lamps? I would also like to know the diameters.

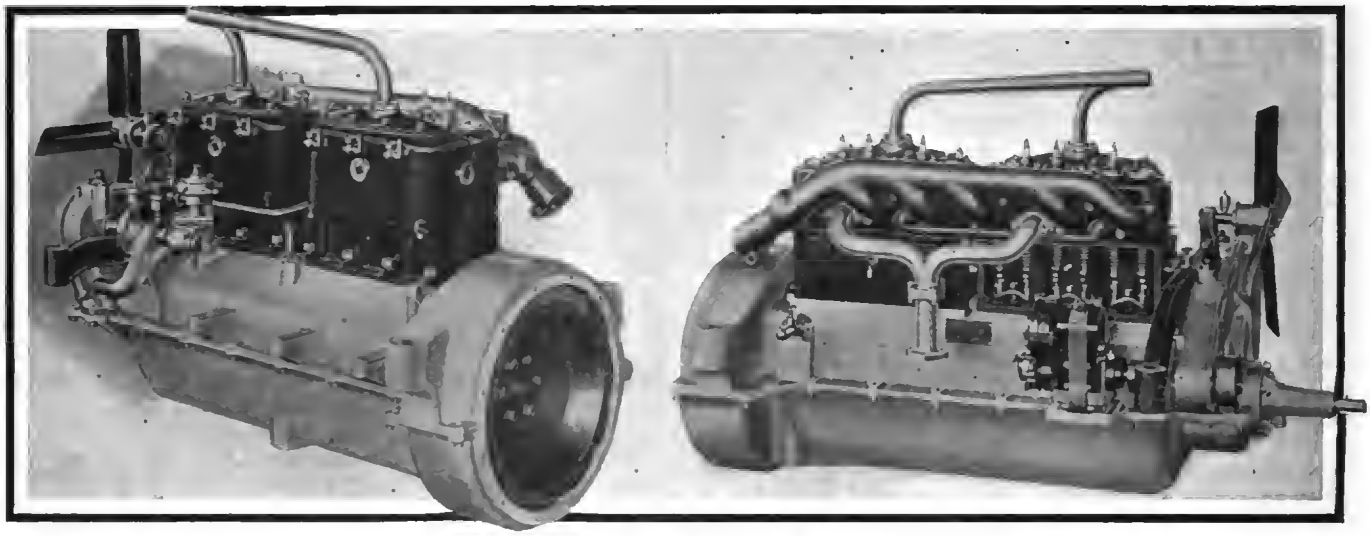
Altoona, Pa. READER.

—The following table will give you the data you require on standard Edison base lamps. By adding up the amperage of the lamps you intend using you will be able to tell what your battery requirements are.

DATA ON STANDARD EDISON BASE LAMPS

Style	Location	Diameter	Voltage	Candle Power	Amperes Required	Efficiency Watts Per Candle Power
1.	Head	2 1/16"	6	15	2.5	1.00
				18	3.0	
				21	3.5	
				24	4.0	
2.	Head	1½"	6	9	1.5	1.00
				12	2.0	
				15	2.5	
				18	3.0	
3.	Rear or side	1"	6	1.5	0.31	1.25
4.	Rear or side	¾"	6	1.5	0.31	1.25
				2.0	0.42	
				3.0	0.63	
5.	Rear or dash	¾"	3	1.0	0.42	1.25

Continental Meets Demand for Light Six



Two views of the Continental motor, showing design of magneto drive manifolds and valve covering

BELIEVING that the 1914 season will be featured by a demand for light sixes, the Continental Motor Mfg. Co. has brought out a motor especially designed to take care of that class of car. This motor is to be known as the 6P, and the company has provided itself with jigs and fixtures to meet the demand for this type of engine.

According to Continental practice the motor has been designed to be used independently or in the form of a complete power plant of unit construction with a multiple-disk clutch and three or four-speed selected gearset.

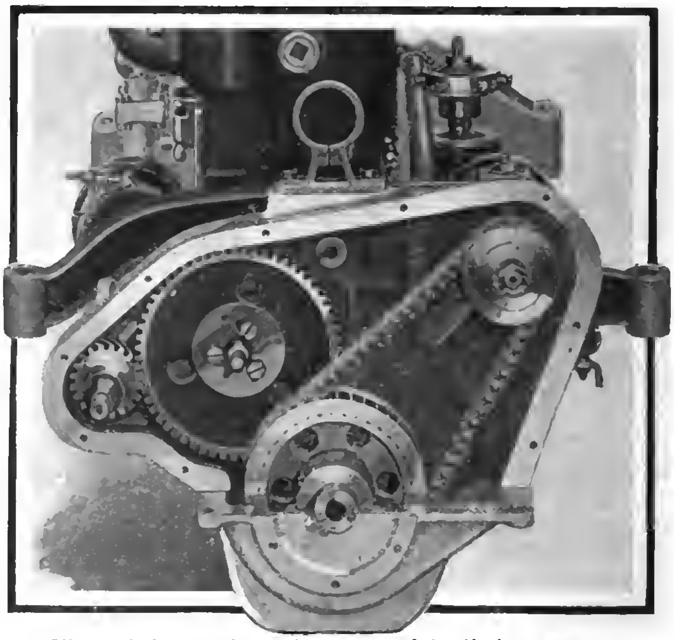
The motor has a bore of 3.75 inches and a stroke of 5.25 inches, giving a rating of 34 horsepower under the S. A. E rating. The cylinders are of the L-type cast in two blocks of three, giving a motor which is very short for a six-cylinder type. It will go under a 40-inch hood without crowding and the total weight, inclusive of flywheel and regular equipment, is but 600 pounds.

Three-point suspension is used with this power plant, thus avoiding any twisting strains on the crankcase. The pivot support is located at the front of the motor and is supplied with a bronze bushing and a lubricator so that there will be no chance of wear and noise at this point. The intake gas passage is cored inside each block cylinder and allows the use of a simple Y-shaped intake manifold.

To further carry out the idea of the designers in having a simple exterior, the valve action has been completely inclosed by two metal covers, each of which is held in place by a single wing nut. The covers can be quickly removed and act as a silence feature besides protecting the action from dirt and dust and permitting the stems and tappet rods to operate with plenty of lubrication.

Considerable latitude is allowed the car manufacturer in that any of the standard forms of equipment may be fitted. The motor can accommodate any type of magneto, dynamo or ignition and lighting device. It is also designed for either right or left drive and center control. The crankcase is built to accommodate any type of cranking motor mounting.

The oil is circulated by means of a gear pump, with positive multiple feeds, which forces the oil directly to the three main bearings, whence it is returned to the reservoir in the crankcase. The overflow from the front main bearings falls into a pocket in the timing gearcase, in which the large sprocket on the crankshaft and the silent chain is partly submerged. This carries oil up to the timing gears and lubricates all the bearings on the front end of the motor. In order that all the wells under the different connecting-rods be supplied with oil constantly and in equal amounts, the lubrication is forced by the gear pumps to each one of the wells in which the connecting-rods dip, so that an absolutely constant level is retained at any motor speed and under any condition of road travel.



Silent chain starting drive mounted in timing gearcase

Another noteworthy point is the silent-chain drive for starting purposes which runs in the timing gearcase. The chain runs in a constant bath of oil and is noiseless. It also drives the pump and commutator shaft and possibly an electric generator when not doing duty as an engine starter. The timing gears are helically cut.

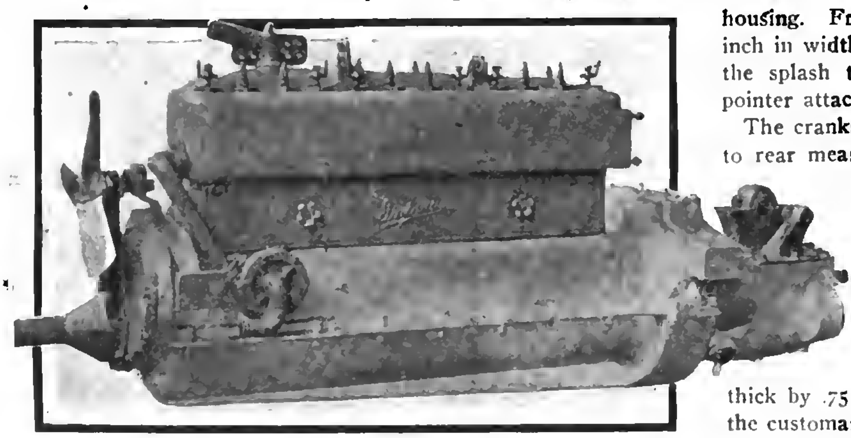
The water circulation is well cared for by a powerful centrifugal pump, which pumps the cooled water directly under the valves to the hottest point.

Milwaukee Casts Exhaust with Cylinders

THE Milwaukee Motor Co. has brought out something new in the way of a block motor. This motor is made in either the six or four-cylinder type, and has several new features of prominence. Important among these is the fact that the exhaust manifold is cast integral with the cylinders. This gives the motor an exceptionally clean appearance and great neatness, the only exterior moving parts being the fan and the pump and magneto shaft.

The motor has a bore of 4.125 inches and a stroke of 5.5 inches. The cylinders are cast in one block and are of the L-head type. The valves are all on the left side of the motor. The opposite sides of the motor are shown at the bottom of this page, and it will be noted that the intake manifold enters the cylinder casting on the side opposite the valves. The exhaust manifold is contained in the cylinder casting along the valve side of the motor, as may be seen in the smaller of the two accompanying illustrations. The manifold terminates in a flat flange at the rear end of the block casting and is at this point connected to the regular exhaust pipe. The terminating flange is rectangular in shape and a bolt is located at each of the four corners for the purpose of attaching the exhaust pipe.

The valve action is fully inclosed by a single cover plate which extends the entire length of the motor just below the exhaust manifold. It can be removed by turning two wing nuts, thus exposing the entire valve mechanism. On the same side as the valve cover plate and located just below it in the crankcase of the motor is the centrifugal water pump. The water enters the block casting at the forward end and is carried through by the pump action to the manifold, which is bolted on the top of the cylinder casting, as shown in the illustration.



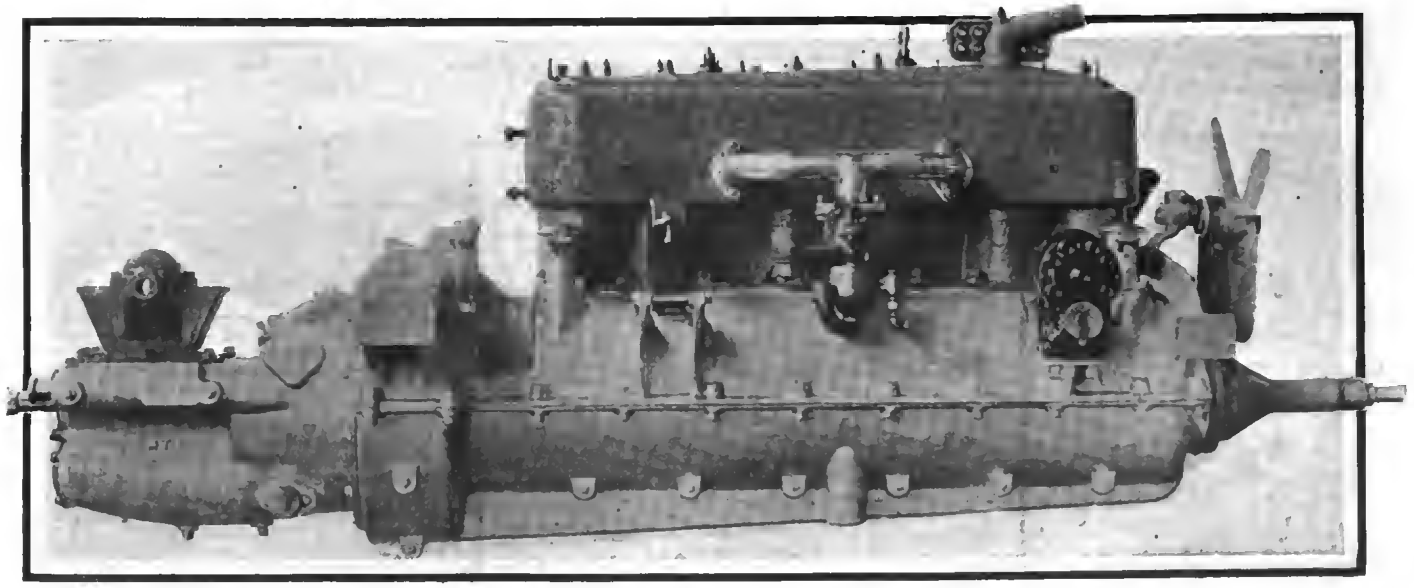
Left side of Milwaukee motor, showing pump

Three-point suspension is used on this motor, two supporting points being at the rear at either side of the crankcase and the third, a universal trunnion is located at the front of the motor behind the timing gearcase. This effectually protects the crankcase against racking strains due to the twisting of the frame. The pistons are 5.125 inches in length. Each carry three piston rings .25 inch wide. These are beveled at the end and are ground on the side to make a good joint with the piston. The piston pins are driven into the piston and oscillate in a bushing at the end of the rod. Above each boss is a small pocket to catch the oil that drips from the piston head.

The lubrication is by constant-level splash. When the motor is not running the oil in the crankcase is all in the bottom of the oil pan and the flywheel housing, except what remains in the four splash troughs under the lower ends of the connecting-rods. When the motor is running the oil in the flywheel housing is picked up by the wheel and carried to its top, where it is thrown off by centrifugal force into a pocket on the side of the housing. From this point it runs along a square channel .375 inch in width, which is cast in the crankcase and is deposited in the splash troughs. The oil level may be determined by a pointer attached to a float operating in a guide.

The crankshaft bearings are three in number, and from front to rear measure 2.75, 3.125 and 4.5 inches in length. They are all 2 inches in diameter. The rear bearing cap is held in place by four through bolts. The center and front bearings are held in place by two through bolts each.

The gearset and clutch are contained in a bell-shaped casting which is a unit with the aluminum crankcase. The clutch is made up of twenty-five large and twenty-four small steel rings .0625 inch thick by .75 inch wide, bent at an angle of 20 degrees. It is of the customary disk clutch design. The gearset is carried on ball bearings and has three forward speeds.



Right or intake side of Milwaukee block six motor, illustrating simple manifold, magneto drive and unit construction

Quadruplex Carbureter Has Four Jets

THE Quadruplex carbureter, as its name implies, has four means of mixing the gasoline with air. Carbureters of the multiple-jet type and each of the four points of mixture has a separate jet. The carbureter, in fact, might be called a multiple-venturi type because there is a venturi-shaped passage around each jet. Fig. 2 gives the sectional view of the carbureter and also a view through each of the four jets.

The carbureter has an eccentric-float feed. The float is not circular as is customary but only extends part of the way around the hemispherical bowl which forms the float chamber. Another unusual point is that the gasoline enters directly through the bottom of the float bowl at its central point. The needle valve controlling the flow of the gasoline is located on the axis of the hemisphere forming the float chamber and is controlled by the customary lever arrangement which keeps the gasoline at its proper level. This part of the mechanism is clearly illustrated in Fig. 2. In the main section of the carbureter is shown the number 1 jet, A. This is the primary point of mixture and constitutes the fuel feed at low speed. The gasoline passes from the float chamber up the vertical passage to the jet which is shown located in the venturi. This jet corresponds directly to the needle valve in the ordinary type of carbureter and is directly adjustable by means of the slotted-screw head at the top of the needle. The primary mixture is drawn directly through the cored passage to the intake manifold and is unobstructed, save by a web in the carbureter casting through which the priming rod passes.

At very low speeds or when running idle the primary jet takes care of the carburetion. When the throttle is entirely closed the gasoline passes through a bypass D just above the primary venturi. This leads directly to the intake and is designed to be sufficient to run the motor when the butterfly throttle is entirely closed.

After the motor reaches a low intermediate speed, the second jet B comes into play. This jet is regulated by gravity. The valve is lifted off its seat by the suction induced in the inlet passage when the throttle is opened. The weight of this valve is fixed and should not be changed except at the factory. The adjustment, however, of the spray nozzle at the number 2 jet may be regulated in the same manner as that of first jet. As will be seen by close study of the illustration, the needle valve governs the supply of gasoline coming up through a central cored passage. The gasoline, after flowing past the needle, goes through small holes pierced in the needle-valve retaining tube. These holes lead directly into the narrowest part of the venturi opening. In this manner gasoline is taken from several points in the venturi opening and an atomizing effect is secured. The other needle valves in the other three jets are arranged in the same manner. When the gravity-seated valves are lifted the suction falls on the small holes in the venturi and the gasoline spray is drawn from them and rushes through the intake passage and mixes with the fuel taken from the primary jet.

The supplementary jet B and the primary jet A are the only ones requiring adjustment when the installation of the carbureter is made. Auxiliary jets C and D are set at the factory and require no change. It will be noted that the weighted valves B, C and D each operate under a different suction on account of their different weights. The mixtures furnished by each of the jets vary in richness and the jets are so designed that the proper mixture will be formed for any given speed. The three gravity valves are of different weights and when giving

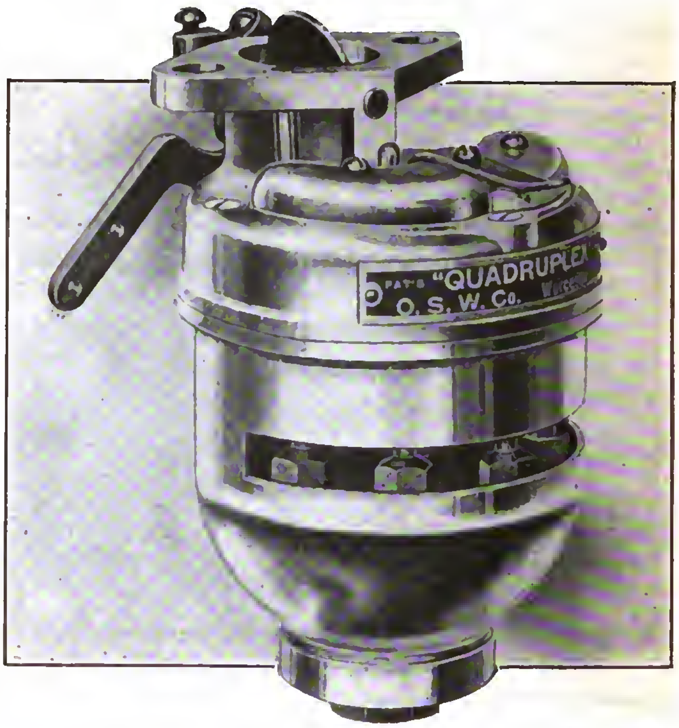


Fig. 1—Exterior of the quadruplex carbureter, showing hemispherical bowl

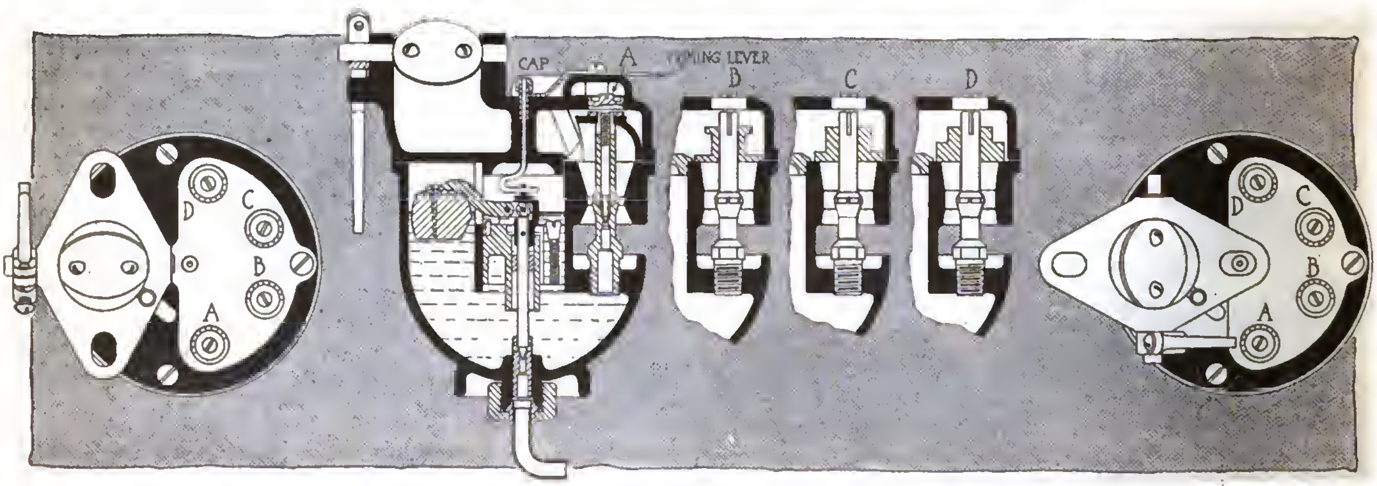

Fig. 2—Section through the Quadruplex carbureter illustrating the four venturi passages and jets

Side view of the Motokart, showing its size as compared to its driver

the maximum power of the engine all of them will be lifted.

The carbureter has no springs or cams and the only adjustment is for gasoline. Each of the four needle valves has numbered micrometer graduations operated from above by a screwdriver, and when once set the same adjustment can always be again reached by noting the numbers and recording them. The micrometer adjustments are shown in the plan views above the sections. The carbureter is furnished with a hot air intake mouthpiece clamped around the exterior of the carbureter and provided with a priming butterfly valve in the outlet to assist in starting in cold weather. The outlet is also arranged for the attachment of a flexible metal hose which can be led in almost any direction to the exhaust manifold upon which a hot air box is installed.

Paris Sweepers Save 12 to 60 Per Cent.

(*Continued from page 1065*)

control and very rapid action, so that it is possible for the operator to instantly cut off the flow of water to avoid splashing pedestrians.

The water pump is engaged by means of a short lever on the right-hand side of the driver's seat. Pivoted at the base of the dashboard are four levers. Two of these operate the piston valves at the inlet end of the main feed pipes, and the two others a similar pair of valves at the sprinkler end. These four being opened to the required degree, the operator confines his control to the guards.

The rotary brush is placed diagonally under the chassis. Diagonally across the frame from the differential housing to a point immediately to the rear of the dashboard, is a horizontal shaft driven by worm gearing from the differential, and having a bevel pinion at its forward end. The worm and worm wheel within the differential housing are constantly in mesh, but the horizontal shaft carries a dog clutch by which the movement can be interrupted through the operation of a side lever. This lever, which is placed immediately to the left of the driver, serves both to engage and disengage the clutch and at the same time to raise and lower the brush. The bevel pinion at the forward end of the diagonal shaft engages with another pinion having the same number of teeth on a vertical shaft just outside the frame member. At the base of this shaft is a second pair of bevel gears having respectively twelve and eighteen teeth, the driven pinion being mounted on the brush shaft. The relation of the sets of gears is such that the brush revolves at one-ninth the speed of the road wheels. As the brush has to be raised and lowered at frequent intervals, and has also to be regulated for height as the bristles become worn, the vertical shaft is telescoping and is also incased by a couple of telescopic tubes. As a final protection, a leather boot is placed around the entire shaft.

New Light Delivery Car

The Motokart Is the First Four-Wheeled Vehicle of This Type To Appear on the Market—It Is Designed for Use in Cities

ALTHOUGH there are a number of light, three-wheeled delivery motor vehicles on the market, it remained for the Tarrytown Motor Car Co., Inc., to bring out the first four-wheel light car especially designed for urban parcel delivery service. This car is adapted to the delivery requirements of butchers, grocers, dairymen, bakers, laundrymen, florists, milliners, etc. An idea of the size of the machine may be gained from the accompanying illustration, which also indicates the light but durable construction used. Seeking for a trade name for the vehicle which would be distinctive, the company adopted the original word "Motokart."

The power unit of the car consists of a two-cylinder motor with cylinders 3.625 by 4 inches which delivers 10.53 A. L. A. M. horsepower. Cooling is effected by the thermo-syphon system. The transmission of the power is by means of a friction drive which provides a wide range of speeds and at the same time precludes the possibility of stripping gears, one of the greatest troubles when inexperienced drivers are given charge of delivery cars using the gear type of transmission.

In appearance the car somewhat resembles the motorcycle or cyclecar types of motor delivery vehicles, the main difference from the motorcycle consisting in the use of four wheels instead of three. As may be seen in the illustration, the driver is seated at the rear of the parcel box directly over the rear axle.

The operation of the car is extremely simple and all actuating levers may be seen in the illustration, comprising the pedal for the clutch, the steering column and wheel and the lever for changing the speed on the friction disk mounted underneath the steering wheel.

Large Parcel Box

The machine has a pressed steel frame, the wheelbase being 65 inches while the tread is 44, the designers having given considerable attention to keeping the car as small as is logically possible in order to facilitate handling in crowded streets. However, the dimensions of the parcel box have been made as large as the size of the vehicle permits, being 48 inches long, 34 inches high and 32 inches wide, the cubical area of the box being 30 square feet. The load capacity of the vehicle is 400 to 500 pounds.

The body used is of metal and the spring suspension is designed to protect fragile merchandise, the springs themselves being of the semi-elliptic type 26 by 2.5 inches. The easy riding qualities of the car are enhanced by the use of wire wheels and pneumatic tires, the lightness of the vehicle insuring low tire and maintenance cost.

As may be seen from the illustration, the car is fitted with mud-guards over each wheel and with a step at the side for the entrance of the driver. The gasoline tank is carried under the seat, while the cooling water tank is contained in the upper part of the rear portion of the parcel delivery box. Access to the parcel box is through doors at the front, the interior of the box permitting of various shelf arrangements to suit the convenience of demands of various trades.

The company has established a factory at Tarrytown, N. Y., its New York office being at 1790 Broadway. It is expected that deliveries will be begun not later than June 15. The price of the machine is $400.

An interested gathering of engineers watched the conclusion of the 300-hour run of the Packard motor

Full Report of Packard Motor Test

Details of the Motor Performance During 300-Hour Run Given Out by A.C.A.

NEW YORK, May 20—The complete report of the 300-hour test of a Packard motor by the testing laboratory of the Automobile Club of America was given out this evening by Herbert Chase, laboratory engineer, and is printed in full herewith. This report shows that the motor made a non-stop run for 300 hours, the only stop that actually occurred during the test being one of 45 seconds caused by air in the gasoline feed pipe, but as this stop was not due to the motor the run must be considered a non-stop one.

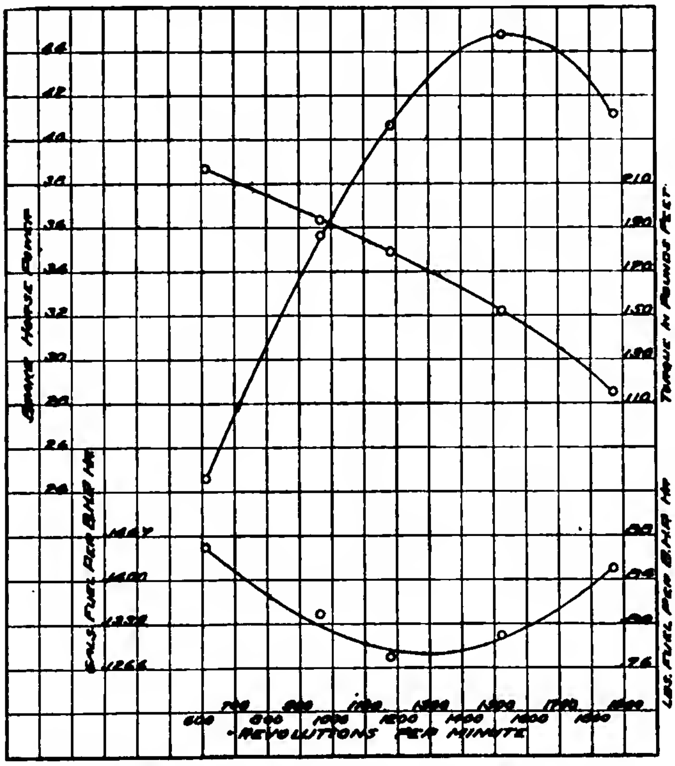

Chart of the brake horsepower run to determine maximum

During the test the motor showed an average horsepower of 35.7, the crankshaft speed averaging 1,208 revolutions per minute.

Fourteen hundred and thirty eight gallons of gasoline were consumed, or an average of 4.79 gallons per hour, this being equivalent to .134 gallon per horsepower-hour. In weight the gasoline consumed amounted to 8,671.4 pounds. It was of 63 Baumé gravity, or a specific gravity of .727.

During the 300 hours 321.9 gallons of lubricating oil were used, or 1.07 gallons per hour of test. By weight the oil amounted to 2,319.5 pounds. During the first part of the test Invader crystal medium oil was used and during the last part Polarine.

The average temperature of the water entering the cylinder jackets was 125 degrees Fahrenheit; the average temperature of the water leaving the jackets was 140 degrees. Instead of using the car radiator a water tank, as customary in all motor tests, was employed.

The report shows that two adjustments of the exhaust valve tappet on No. 1 cylinder, one at the 147th hour and the other at the 152nd hour. Two spark-plugs were replaced, one at 106th hour, the other at the 128th hour. The screw covers above certain of the valves were tightened. The screws which fasten the air valve cage of the carbureter were tightened once during the run.

The report shows that during the test the throttle was wired wide open from start to finish and the spark at the full-advanced position.

The motor was a Packard 1914 38-six, familiarly known as the Packard small six. Its bore and stroke are 4 by 5.5 inches, and has an S. A. E. rating of 38.4 horsepower.

According to the rules governing the test, printed in full in THE AUTOMOBILE May 1, page 926, a preliminary series of short tests of 3 minutes each was made to determine the maximum horsepower of the motor, which showed 44.9 horsepower at 1,533 crankshaft revolutions per minute. During the duration test of 300 hours the rules called for an average horsepower of more than 70 per cent. of this, in other words, the average horsepower for the 300 hours was to be somewhere above 31.43 horsepower.

The horsepower chart reproduced herewith shows the power curve for the entire 300 hours, the vertical lines marking the time off into 5-hour intervals. According to this chart the lowest horsepower mark appears at the 106th hour at which time the first spark-plug was changed. The changing of the second plug at the 128th hour does not show any drop in power on the chart. Slight downward projections on the power curve are shown at the 147th and also at the 152nd hour, when the tappet was being adjusted.

The official record of the tests shows that it began at 10:43 Saturday night, May 3, and was completed at 10:43 Friday afternoon, May 16, exactly 12.5 days. Running a motor at an average crankshaft speed of 1,208 crankshaft revolutions per minute gives a total of 21,744,000 revolutions. Were the motor running in the car at this speed and with the gear ratio used it would be averaging slightly in excess of 37 miles per hour and during the 300 hours would cover a mileage of 11,100. Roughly calculating it is 4,000 miles from New York to San Francisco, so that this test in mileage is equivalent to twice across the continent and from New York to beyond Salt Lake City on the third trip.

The complete report follows:

"This is to certify that the Technical Committee of the Automobile Club of America has tested the Packard motor, manufactured by the Packard Motor Car Co., with the following results:

"Endurance Run—The motor ran continuously with wide-open throttle and fully-advanced spark for a period of 300 hours at an average speed of 1,208 revolutions per minute. During this interval the average brake load at 1 foot radius was 155.1 pounds, giving a resultant average brake-horsepower of 35.7. The lowest horsepower reading for any 15-minute interval during the entire 300 hours was 28.7.

"The total fuel consumed during the run was 8,671.4 pounds, equivalent to 1,438 gallons, an average consumption of 0.81 pound (0.134 gallon) per brake-horsepower-hour.

"The total oil consumed was 2,319.5 pounds, equivalent to 321.9 gallons, an average of 1.07 gallons per hour. (See chart No. 1 and Table No. 1 for record of power variation.)

"Runs at Various Speeds—Prior to the endurance run a series of short runs, each of 3 minutes' duration, with throttle wide open and spark set for maximum power, was made to determine the maximum power of the motor.

"The maximum power developed was 44 horsepower at 1,533 crankshaft revolutions per minute. (See Table No. 2 and Chart No. 2 for record of torque and power at various speeds.)

"Particulars Regarding Motor—The motor, which is designated by the manufacturers as model 13-38, is of the four-cycle type having six cylinders of 4-inch bore. The stroke is 5.5 inches. The valves, which are of the poppet type, are all located on the same side of the motor and are actuated from a single camshaft.

"The weight of the motor, including flywheel, pump, fan, carbureter, all manifolds, magneto and complete ignition system, self-starter, motor, clutch and its casing, brake starter and clutch, pedal levers and half of universal joint, was 973 pounds.

"Lubrication—The motor was not taken down for examination, but the owners state the lubrication is accomplished as follows: A gear pump draws oil from the sump and delivers it to the main bearings under pressure. From these it flows through the hollow crankshaft to the big-end bearings and thence to the wristpins through pipes attached to the connecting-rods. The oil is also delivered to the cylinder walls for lubrication of the pistons passing through a valve which in the normal operation of the car is opened and close by the accelerator pedal. During this test the valve was wired wide open.

"The exhaust from the motor was smoky and considerable carbon deposits were observed on the exhaust valves after the test.

"Two different brands of oil were used during the test, namely, Invader crystal medium and Polarine.

"Fuel—The fuel used during the test was gasoline having an average specific gravity of 63 degrees Baumé, equivalent to .727 specific gravity.

"Carburetion and Ignition—The Packard carbureter was

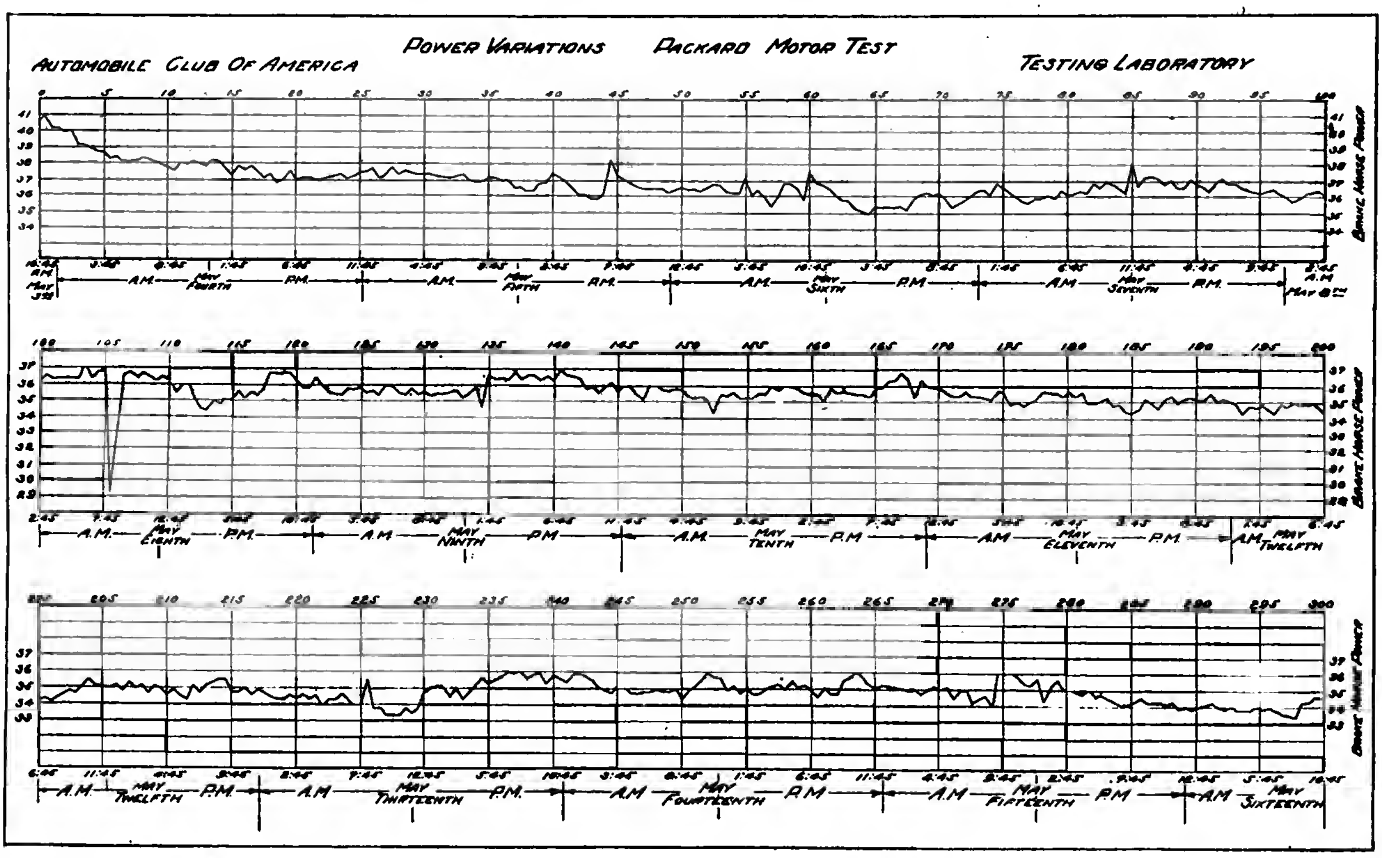

Chart showing the performance of the motor during the 300 hours, plotted on average horsepowers at each half hour during entire run

used, while the ignition was furnished by a Bosch model 5 DU 6 magneto.

"COOLING AND EXHAUST—The motor was cooled during the test by water circulated by a centrifugal pump. The average temperature of the water entering and leaving the motor was 125 degrees Fahrenheit and 140 degrees, respectively.

"The motor exhausted through a 30-inch length of 2-inch pipe into an expansion chamber having a 3-inch standard pipe outlet.

"During the endurance test a blower was used to direct upon the motor a blast of air having a velocity of about 30 miles per hour. The fan, which is regularly used with the motor, was also kept in operation.

"The average temperature of the air during the test was 68 degrees Fahrenheit; and the average barometer readings 29.19 inches of mercury.

"ADJUSTMENTS.—The following adjustments were made during the 300-hour run.*

"During the 147th hour the lock nut on the exhaust valve tappet of No. 1 cylinder was found to be loose and the tappet in such position that the valve did not seat properly. The tappet was screwed down and locked. It was later found that this tappet had been set for more clearance than it had at the start of the test. It was consequently reset at 152d hour, to its original position, where it remained to the end of the test. While this adjustment was being obtained the power fell momentarily, but aside from this the adjustments did not result in any greater variation in the power developed than were recorded during periods when no adjustments were made.

"Two spark plugs were replaced without stopping the motor. One during the 106th and one during the 128th hour.

"The screw covers above certain of the valves were tightened.

"The screws which fasten the cage containing the carbureter air valve in place were also tightened once during the run.

"A slight leak around the gland on the water pump was present during the greater part of the test, but no adjustment thereof was made."

F. R. HUTTON,
Chairman Technical Committee.
HERBERT CHASE,
Laboratory Engineer.

The table below shows the story of the endurance test and the preliminary power test. Pressure on the fuel was often required even while the strainer was absolutely clean. The pressure on the fuel varied between atmospheric and 2 inches of mercury during the 300 hours.

*Interruption of the gasoline supply due to air in the feed pipe during the 60th hour caused the motor to stop for approximately 45 seconds. Since this stop was not due to any fault of the motor the run is considered continuous under the rules.

Accessories for the Automobilist

Fig. 2—Use of Flexilyte lamp on the road

FLEXILYTE—A clever and useful accessory has been devised by the L. A. Williamson Co., 1790 Broadway, New York City. The device is known as the Flexilyte, Figs. 1 and 2, and is constructed to serve as a trouble-hunting and general search light for automobilists, both on the road and in the garage. Fig. 1 shows the appearance of the Flexilyte very well, it being composed of a gun-metal casing to which the holder H, formed like a steering wheel, is attached by means of a pin. The rim of the drum-shaped casing is cut at C so as to permit the wire-cord to pass through it which leads from the battery terminals to the hub-formed lamp socket arranged centrally in the drum-shaped casing of the device. On the back side of the casing there is a small pawl P engaging flat serrations in the rear wall of the socket-hub, so that if the latter is turned in one direction, the reversal of the movement is prevented by P. The piece Q, pivoted around a pin secured to and above the surface of the socket wall, is turnable around this pin; it is ordinarily held in engagement with a hole in the socket wall, its end carrying a ball which fits into the hole. If this end is free, the piece Q may be thrown over toward the casing periphery and the socket-hub may be so turned that the pawl prevents its return. By freeing the pawl from the serrations, the hub is permitted to turn by pulling the cord, so that any desired length of wound wire may be pulled out of the casing and rewound by turning the piece Q. The ends of the cord are fitted with spring-clip terminals which may be secured to any type of battery poles. Fig. 2 shows an obviously very useful application of the Flexilyte device, one of the many cases where the powerful tungsten bulb can be worked to advantage.

Packard Valve Cap Tool—Asch & Co., 1777 Broadway, New York City, handle the valve cap tool shown in Fig. 3, which is specially designed to fit Packard motors. The tool consists of a hexagonal steel prism into the side of which a steel rod is fitted to form a handle. The hexagon is so proportioned as to exactly fit the depression in Packard valve caps, so that it is extremely easy to remove the latter by inserting the tool and giving it a turn or two. Such a device is, of course, a great time saver in a repair shop. Tools to fit the valve caps of many other prominent makes will be brought out soon.

GO Motor-Speeder—Fig. 4 illustrates the GO Motor-Speeder, made by the Fudge Bros. Mfg. Co., Marion, Ind. This device has the purpose of supplying warm auxiliary air for preheating and completely breaking up the mixture, and supplying it in the correct amount, no matter what the throttle opening of the motor might be. To attain this end, the Fudge concern has combined the device proper, D in Fig. 4, which is a cup all closed with the exception of a screened air intake, with a valve contained in D and connected by C to the throttle rod R of the carbureter, so that any movement of the latter produces a corresponding adjustment of the speeder valve. The air taken in through the hole of D passed through the compressing coupling at the lower end of the device and through a tube C coiled around the exhaust pipe to the intake manifold, which it enters through a nozzle N formed with a number of small holes. To regulate the capacity of the auxiliary air lead, primarily, a cock is placed just ahead of the nozzle N. This device has the great advantage that when its capacity has once been adjusted by properly positioning the cock, it remains in the right adjustment and requires no further attention. It may be mounted in a very short time, being attached to the motor frame by means of the bracket seen in Fig. 4 and after this it serves for any length of time without demanding any attention.

Rust-No Graphite—The same company also handles the Rust-No graphite stick for preventing the tires rusting onto rims, Fig. 7. This article is composed of graphite powder held together by an oily binder and being formed in the shape here illustrated. The compound is dry and hardly blackens the hands; at any rate, one end is covered with paper which is printed with instructions for the use of it. It is used for rubbing the contacting faces of rims and tires before mounting the latter on the former. The graphite then forms a thin layer between rubber and metal and prevents the adhesion of the two materials. The stick may also be used for the lubrication of such parts as spring leaves by rubbing the latter with it, or shaving some of the graphite and squeezing it between the leaves.

Taylor Noil Tire Pump—The Taylor Mfg. Co., P. O. Box 485, Chicago, Ill., is the maker of a new engine-driven tire pump, which is permanently installed on the motor or chassis frame and is operated by a sliding gear which may be brought into engagement with a half-time or other pinion, the engagement and disengagement of the gears being controlled by means handled by the driver. The pump is of the reciprocating piston type. The piston is of mushroom design, somewhat similar in shape to a valve.

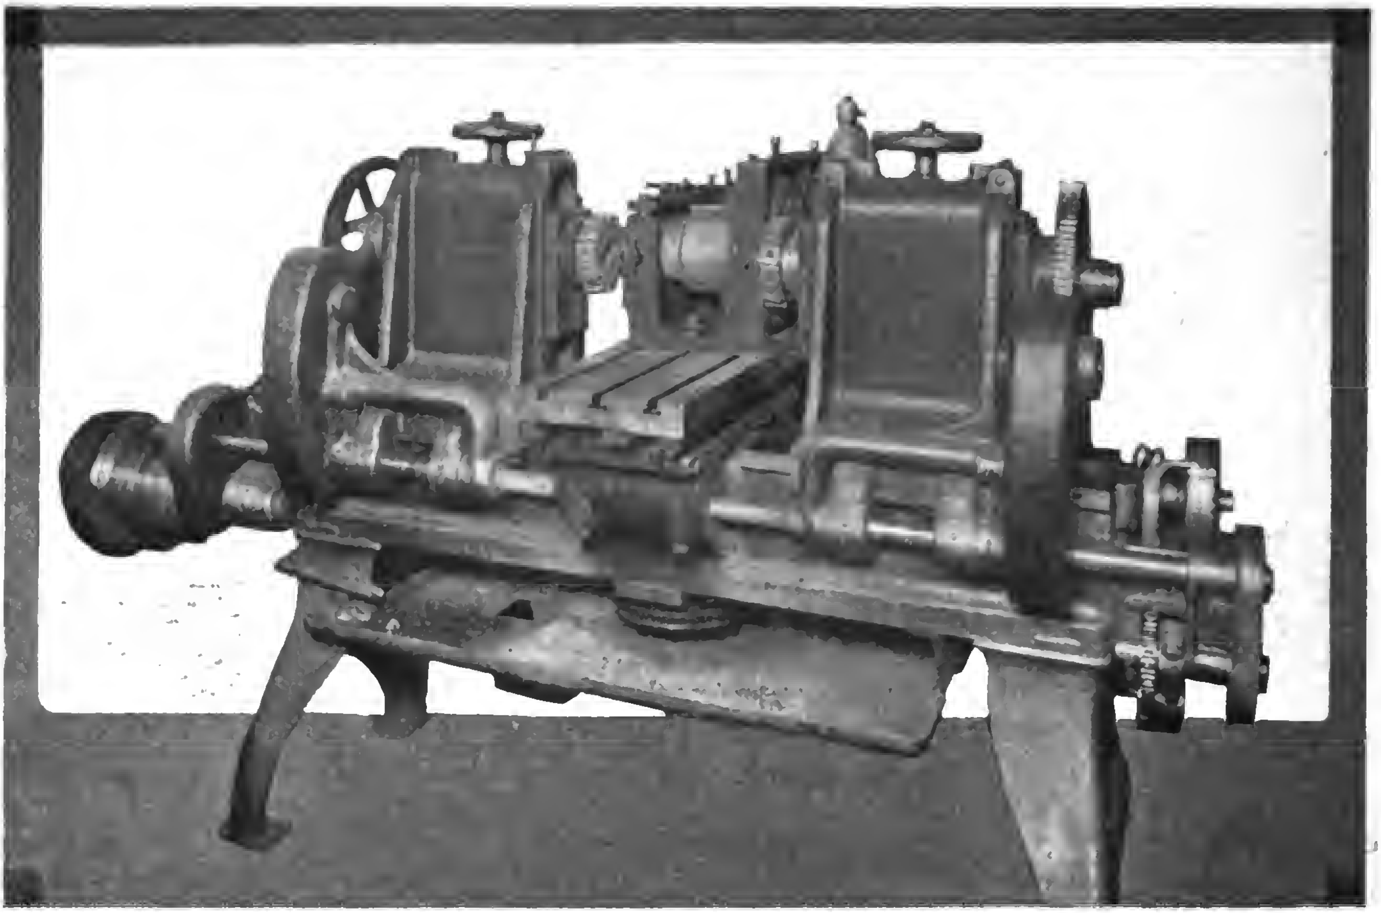
Factory Miscellany



Milling machine for finishing Moon cylinders employed in the factory of the company at St. Louis, Mo.

IN comparing the advantages of the T-head and L-head types of cylinders laymen frequently omit the consideration of machining. It is evident that it will cost more to do machine work on two sides of a casting than on one because there will be double the number of set-up jobs. Where a moderate-priced car uses the T-head type of cylinder it is evident that machines will have to be employed to keep the cost of labor on the cylinders down to the lowest possible point. The machine shown in the above illustration does this in the Moon factory at St. Louis. This machine is capable of handling eight cylinders at one time and all of the outside milling work on these cylinders is performed in two operations and by one man. The first operation consists in the milling of the tops and bottoms of the cylinders at the same time. After these are completed, the cylinders are turned upright and both sides are milled. This includes the milling of the intake and exhaust manifold bosses, the water connections and the valve covering plates. One man handles all the set-up work and no time is lost in this respect as he sets up one pair of cylinders while another pair is being milled. One man can turn out forty cylinder castings in a day. Naturally, this machine is an important economic factor.

NEW DUFF PLANT—The Duff Mfg. Co., recently moved into its new factory, located on Preble avenue, N. S., Pittsburgh, Pa. The main factory building is 550 feet long by 125 feet wide, affording an area of over 68,000 square feet. The entire factory building and office building is built fireproof, of steel, brick and concrete construction. The width of the building, 125 feet, is divided into four bays, 30 feet, 35 feet and then two 30-foot bays. The crane bay and side bays are designed to provide for a telpherage system and all roof trusses are so designed as to permit the operation of the crane and telpher hoist in connection therewith in practically every square foot of the building. Another feature is the central oil distributing system which comprehends all of the machine shop and which provides that all of the machines are fed from a central point by gravity, the returned oil being passed through a series of strainers into a large tank, from which it is electrically pumped to the gravity tank and again passed through the entire system. The floors of the main machine shop are constructed of asphalt block, which is mainly a limestone block of great durability. The floors of the heat-treating department and forge room arela id with a hard paving block, and floors of the warehouse, lavatories, tool supply departments, boiler and fan rooms are concrete. There are no solid partitions in the entire factory building, as heavy wire screening, 10 feet in height is used exclusively to separate the stock rooms, etc.

Hewitt Plans Factory—The Hewitt Rubber Co., Buffalo, N. Y., has filed plans for a new three-story brick factory at 240 Kensington avenue, to cost $175,000.

Gibson Will Build—The Gibson Motor Car Co., Pittsburgh, Pa., will build an automobile plant as soon as a site can be decided upon. The company will manufacture commercial trucks.

Automobile Plant for Louisville—The Crown Motor Car Co. is being organized in Louisville, Ky., with a capital of $500,000. It will make a cheap automobile, the intention being to market a two-passenger runabout to sell at $350.

Ausman Truck Factory Planned—A factory for manufacture of the Ausman motor trucks is to be established at Chattanooga, Tenn., with capital supplied by the Manufacturers' Assn. of that city. The plant will cost $100,000.

Big U. S. Tire Output—The April output of the Hartford, Conn., plant of the United States Tire Co. comprised 70,000 bicycle, 35,000 automobile and 150 tons of vehicle tires. The new power house, 108 by 68 feet, is nearly completed. The factory now employs about 1,700 hands.

Mansfield Tire Increases Output—The Mansfield Tire & Rubber Co., Mansfield, O., is increasing its tire output to 500 automobile tires a day.

Fourteen Plants Now—The home of the Detroit, Mich., Curling Club has been secured by the Studebaker Corp., and is now plant 14 in that company's system.

Detroit Top Company Builds—Meyers & Blackstock, Detroit, Mich., will soon open a factory at St. Louis, Mich., for the manufacture of automobile and buggy tops and similar articles.

Studebaker's $60,000 Assembling Plant—Plans were completed recently for a new two-story $60,000 building in St. Louis, Mo., for the Studebaker Corp. of America. This building will be an assembling plant. It will be of brick, concrete and terra cotta.

Buffalo Spring Company's Factory—The Buffalo, N. Y., Automobile Spring Co., recently incorporated, has leased for manufacturing purposes the two-story brick factory building at 146 Virginia street.

Painesville Citizens Want Factory—The citizens of Painesville, O., are agitating the question of securing an automobile factory for that town. The Vulcan Mfg. Co., recently incorporated to manufacture automobiles, is the concern which may locate in that city.

Heinz Electric Needs Men—Two hundred more men will be required for the factory of the Heinz Electric Co., Walkerville, Ont., this Lowell, Mass., concern having located there for the purpose of manufacturing spark coils and electric appliances for the Canadian and export trade.

Goodrich Purchases Land—The B. F. Goodrich Co. has secured some land on Chippewa Creek, Ont., 1 mile from Niagara River, on which it proposes to construct a large factory. The site was purchased from the Ontario Power Co. and that concern will supply the plant with electric power. The new rubber concern will manufacture rubber tires for automobiles as well as other rubber goods. Within a year 1,800 workmen will be employed in the plant.

Work on New Tire Plant—Owing to the fact that the ground on which they had planned to place their new building was wanted by the Pennsylvania Railroad, the members of the DeLion Tire and Rubber Co., Trenton, N. J., have changed their plans and will build their new factory about 300 yards from the original site. The building will be of the three-story type of brick and steel construction, which will render it practically fireproof. Cement floors will be used entirely.

Automobile Manufacturing in Canada—The manufacture of motor cars and trucks has made rapid strides in Canada. Windsor and Walkerville have already become the automobile center of that country. This is accounted for by the fact that it is extremely convenient for the Detroit, Mich., manufacturing firms to establish branches so close to the head offices. Among the latest to establish itself there is the Tudhope Motor Co., a branch of the Everett Motor Co., Detroit, Mich., which has purchased 10 acres in Windsor's factory district and has contracted to erect a $75,000 factory. The Tate Electrics, Ltd., financed by Canadian and American interests, has purchased a site in Ford City and is erecting a large automobile plant there.

General view of the main shop of the Duff Mfg. Co., Pittsburgh, Pa., taken prior to occupancy

The Automobile Calendar

Shows, Conventions, Etc.

May 20-23 .... Baltimore, Md., Spring Meeting, American Society of Mechanical Engineers.
June 2-7 .... Racine, Wis., "Made in Racine Exposition," J. I. Case Co.'s foundry.

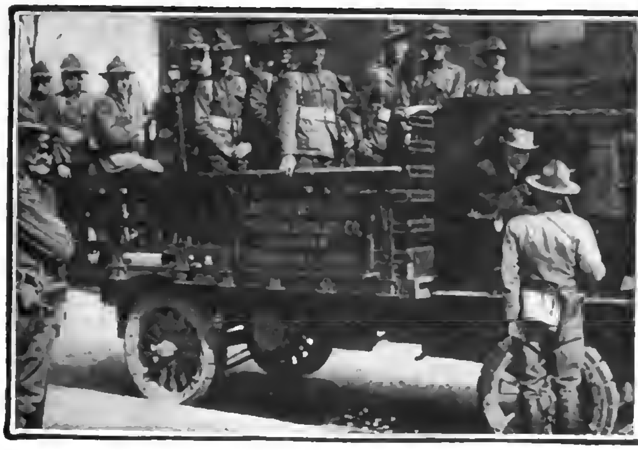
November .... London, Eng., Annual Automobile Exhibition, Olympia.

The Week in the Industry

Engineer — Dealer — Repairman — Garage



Men of Company C, N. Y. N. G., responding to hurry call for protection from rioting strikers and to guard a manufacturing plant in Syracuse, N. Y.

Scene at the recent car strike in Cincinnati, O., where the motor truck replaced the street car. The motormen and conductors were on strike for more pay; as a result all the lines were tied up and the motor truck proved a handy conveyance

TRUCKS IN LABOR STRIKE—Three companies of the New York National Guard were called out to subdue strike riots in Syracuse, N. Y., recently. For the first time in the history of such events in that city, motor vehicles, pleasure cars and trucks played an important part in the arrangements to preserve order. Several large motor trucks and half a dozen touring cars were kept at the Armory and when calls came from any part of the city asking for protection for non-union laborers, the soldiers were hurried to the spot in the trucks.

PROMOTION FOR MAXWELL—R. D. Maxwell has been appointed manager of the Studebaker branch retail store in Los Angeles, Cal.

WELDING FIRM IN VANCOUVER—Among the new industries established in Vancouver, B. C., is the new firm Oxo Welding & Machine Co.

NORMAN HEADS FORD BRANCH—F. B. Norman has been placed in charge of the branch of the Ford Motor Co., Detroit, Mich., in Portland, Ore.

DUNHAM DIAMOND TIRE MANAGER—C. A. Dunham has been appointed Pittsburgh, Pa., manager of the Diamond-Goodrich branch in that city.

PACKARD ADOPTS HARTFORD ABSORBERS—The Packard Motor Car Co., Detroit, Mich., will again adopt the Hartford shock absorber equipment.

LOZIER'S FRISCO BRANCH CHANGED—The San Francisco, Cal., branch of the Lozier Motor Co., Detroit, Mich., will move into larger quarters in the near future.

MCMARTIN PROMOTED—E. J. McMartin, of the Fisk Rubber Co., Chicopee Falls, Mass., branch, has been promoted to manager of the subsidiary branch at Butte, Mont.

TAKES MINNESOTA AIREASE RIGHTS—H. S. Waite, 1334 Nicollet avenue, Minneapolis, Minn., has taken the Minnesota rights for the sale of Airease. He will create agencies.

SHILAND RESIGNS FROM HAVERS—H. E. Shiland, sales manager of the Havers Motor Car Co., Port Huron, Mich., has resigned from that company, same to take effect June 1.

BUGBEE ASSISTANT GENERAL MANAGER—C. S. Bugbee, of Detroit, Mich., has received the appointment of assistant general manager of the Great Western Automobile Co., Peru, Ind.

ROCHESTER CLUB MOVES—The Rochester, N. Y. Automobile Club is moving its headquarters from the Hotel Seneca to Powers Hotel. The new clubroom will be 30 by 35 feet in size.

WALLACE FRANKLIN'S FRISCO MANAGER—W. D. Wallace, formerly of Seattle, Wash., has recently been appointed sales manager of the Franklin Automobile Co., in San Francisco, Cal.

HAYNES PUBLISHES HOUSE ORGAN—The Haynes Automobile Co., Kokomo, Ind., will publish a house organ. The initial number will be published on July 1. It will be a monthly publication.

DAWSON SUCCEEDS KEIP—A. R. Dawson has been made branch manager of the San Francisco, Cal., branch of the Lozier Motor Co., Detroit, Mich. He succeeds F. B. Keip, who recently resigned.

BUS LINE IN SCHENECTADY—An automobile bus line was started recently from Schenectady, N. Y., to Pittsfield, Mass., by Messrs. Welcome and Jordon. Two Packard cars constitute the service.

BULLOCK RESIGNS FROM HERRESHOFF—J. H. Bullock, assistant secretary and treasurer of the Herreshoff Motor Co., Detroit, Mich., has resigned and is in Houston, Tex., at present, having located there temporarily.

NEW INVADER OIL AGENTS—The Beck Corbitt Iron Co., St. Louis, Mo., and the Boyer-Campbell Co., Detroit, Mich., have taken on the full line of the products manufactured by the Invader Oil Co., New York City.

KEROSENE CARBURETOR ON HENDERSONS—The Henderson Motor Car Co., Indianapolis, Ind., announces that it will furnish a Harroun carburetor, using kerosene, at a slight additional charge on any of its second series models.

INDIANAPOLIS SHOW GIVES DIVIDEND—A dividend of 25 per cent. to those who exhibited at the automobile show held in Indianapolis, Ind., during the latter part of March, has been declared by the Indianapolis Automobile Trade Assn.

KELLY-SPRINGFIELD'S NEW QUARTERS—The Kelly-Springfield Tire Co., New York City, has moved into new quarters at Broadway and 57th street. The solid and block tire department will, for the present, remain at 243 West 47th street.

STERNSFELS ADVERTISING MANAGER—C. D. Sternsfels has been appointed advertising manager of the Abendroth & Root Mfg. Co., Newburgh, N. Y., with headquarters at 50 Church street, New York City. This company manufactures motor trucks.

AUTOMOBILE APPAREL FIRM BANKRUPT—A petition in bankruptcy has been filed against C. E. Hottum, a manufacturer of automobile and livery apparel at 12 West 33d street, New York City. The liabilities are alleged to be $7,000 and assets $1,500.

LARGE $40,000 GARAGE FIRE—Fire which broke out in the Lafayette Garage, Lafayette, La., recently, consumed the entire building, together with the contents, consisting of twenty-three automobiles. Estimates of the losses sustained range from $35,000 to $40,000.

Recent Incorporations in the Automobile Field

AUTOMOBILES AND PARTS

BOSTON, MASS.—Britton-Stevens Motors Corp.; capital, $50,000. Incorporators: William H. Britton, Geo. D. Stevens, Chas. F. Pinkham.

BROOKLYN, N. Y.—Lil's Motors Co., Inc.; capital, $4,000; to do a general automobile and taxicab business. Incorporators: Thos. J. Qualey, Ethel McDonald, Geo. H. Wendling.

BUFFALO, N. Y.—Buffalo Automobile Spring Co., Inc.; capital, $10,000. Incorporators: Earl Plants, W. Edward Slater, Harvey Etlinger.

CHICAGO, ILL.—Knight & Kilbourne Patents Co.; capital, $1,000,000; to manufacture automobiles, engines and motors.

CINCINNATI, O.—Queen City Motor Delivery Co.; capital, $50,000; to deal in automobiles. Incorporators: M. C. Heintz, Harry G. Hehman, Albert F. Hehman, Louis Hehman, William F. Ray.

CONNERSVILLE, IND.—Van Auken Electric Car Co.; capital, $10,000; to do a general automobile business. Incorporators: G. C. Babcock, A. K. Babcock, C. L. Millard, B. D. Millard, H. M. Wylie.

DETROIT, MICH.—Monarch Motor Car Co.; capital, $30,000; to manufacture automobiles. Incorporator: August J. Bloom.

GALENA, O.—Galena Auto & Machine Co.; capital, $2,500. Incorporators: C. C. Wilmerton, Kenneth V. Johnston, Roy W. Wilmerton.

HAMILTON, ONT.—Hamilton Cadillac Motor Co.; capital, $40,000; to manufacture motor cars and other vehicles. Incorporators: James Nixon, Frank R. Newberry, James A. Sauriol.

INDIANAPOLIS, IND.—Fisher Automobile Co.; capital, $25,000. Incorporators: Carl G. Fisher, Harry L. Hammond, F. Ellis Hunter.

JACKSONVILLE, FLA.—S. & B. Motor Co.; capital, $10,000. Incorporators: B. D. Spinney, Jos. Lockwood, J. Stewart, Bertram.

JACKSONVILLE, FLA.—White Sales Co.; capital, $100,000; to engage in an automobile business. Incorporators: James R. Collins, P. D. Oakley, N. A. Collins.

JERSEY CITY, N. J.—Model Garage Co.; capital, $25,000; to do a general automobile business. Incorporators: J. F. Autenrieth, H. Finke.

LOUISVILLE, KY.—Automobile Clearing House Co.; capital, $2,500. Incorporators: C. L. Holden, W. J. Welch, Chas. H. Welch.

NEOSHO, MO.—Neosho Automobile Co.; capital, $3,500. Incorporators: J. F. Wills, F. S. Biggs, E. R. Rudy.

NEWCASTLE, IND.—Maxwell-Newcastle Mfg. Co.; capital, $50,000. Incorporators: Russel Willson, Romney L. Willson, Frank C. Olive, Harry Wilder, James W. Wellington.

NEW YORK, N. Y.—Tarrytown Motor Car Co.; capital, $250,000; to deal in automobiles. Incorporators: W. Odell, B. J. Knerr, A. M. Levy.

NEW YORK, N. Y.—Gerleit Auto Spring Wheel Co.; capital, $200,000; to deal in wheels, parts, etc. Incorporators: A. Gerleit, M. Vath, H. Heil.

NEW YORK, N. Y.—Fulton-Post Co., Inc.; capital, $1,000; to deal in motor and motor vehicles. Incorporators: Regis H. Post, William H. Fulton, L. M. Dietrich.

NEW YORK, N. Y.—The Motor-Compressor Co., Inc.; capital, $10,000; to manufacture motors. Incorporators: G. J. Spohrer, Chas. E. Van Vleck, Robert L. Redfield.

SHELBYVILLE, IND.—Meteor Motor Car Co.; capital, $150,000; to do a general automobile business. Incorporators: M. S. Wolfe, F. P. Wolfe, M. E. Hester.

ST. LOUIS, MO.—Admiral Motor Co.; capital, $60,000; to manufacture a new one-thousand pound truck and a light farm tractor.

SYRACUSE, N. Y.—Stowell Motor Car Co.; capital, $30,000; to deal in automobiles and motorcycles. Incorporators: Harry E. Stowell, R. Burns Avery, Fred H. Mabey.

WILMINGTON, DEL.—Victor Motor Car Co.; capital, $100,000; to deal in automobiles.

WYANDANCH, N. Y.—Consolidated Gas & Gasoline Engine Co.; capital, $15,000. Incorporators: Geo. H. Scanlan, F. B. Knowlton, E. J. Forhan.

GARAGES AND ACCESSORIES

BOSTON, MASS.—Massachusetts Garage Association; capital, $5,000. Incorporators: Josiah Hathaway, Chester I. Campbell, Frederick W. Boynton, John E. Savell.

BUFFALO, N. Y.—Frontier Transportation Co.; capital, $200,000; to operate a motor bus line. Incorporators: Giles G. Meindell, Irving F. Cragin, Francis L. Hoff.

BUFFALO, N. Y.—Couch-Georger Tire Agency; capital, $20,000; to handle tires and accessories. Incorporators: C. A. Couch, E. E. Howell, Frank P. Georger.

CHICAGO, ILL.—Vincennes Garage; capital, $2,500. Incorporators: Albert E. Lucius, Edward B. Lucius, J. Scott Matthews.

CHICAGO, ILL.—Ferns Motor Livery; capital, $50,000. Incorporators: M. M. Franey, Asher J. Goldfine, Harry P. Munns.

CLEVELAND, O.—Cleveland Automobile Country Club; capital, $7,500. Incorporator: T. P. Cogwin.

DALLAS, TEX.—American Tire & Rubber Co.; capital, $25,000; to deal in automobile accessories.

DALLAS, TEX.—The Original Punturelfix Co.; capital, $5,000. Incorporators: A. Marks, Vincent L. Hughes, A. F. Weisberg.

DAVENPORT, IA.—Positive Tire Vulcanizer Co.; capital, $10,000; to sell tire vulcanizers. Incorporators: W. G. Sanford, Chas. Huber, J. Reed Lane, P. A. Bendixen.

EAST ST. LOUIS, ILL.—Southern Illinois Traction Co.; capital increased from $1,500,000 to $7,500,000.

HAMILTON, O.—Star Taxicab Co.; capital, $5,000. Incorporators: Geo. C. Skinner, A. M. Skinner, William Miller, Merle Flenner, Millikin Shotts.

INDIANAPOLIS, IND.—Shinauto Mfg. Co.; capital, $10,000; to manufacture motor car polishes and soaps. Incorporators: W. L. Bedford, J. C. Sharp, M. A. Seligman.

MILWAUKEE, WIS.—Economy Motor Fuel Adjusting Co.; to manufacture a new type of carbureter. Incorporators: John McFarland, Max Grass, John J. Handley.

NEW YORK, N. Y.—Multiple Jet Carbureter Co., Inc.; capital, $1,000. Incorporators: Chas. A. Singer, Austin B. Palmer, Chester U. Palmer.

NEW YORK, N. Y.—Auto Polo Corp.; capital, $10,000; to promote auto polo. Incorporators: Hicks A. Weatherbee, Richard R. Sinclair, Philip Huetwohl.

NEW YORK, N. Y.—Troy Auto Bus Corp.; capital, $20,000; to operate an auto bus line. Incorporators: John Burdick, Ernest L. Snyder, John McGlynn.

NEW YORK CITY.—Globe Rubber Tire Mfg. Co.; capital, $1,500,000; to manufacture rubber tires and all accessories for automobiles. Incorporators: Harry D. James, Joseph P. Hell, Spencer Weart.

NEW YORK CITY.—Gallagher Carbureter Co.; capital, $300,000; to manufacture carbureters. Incorporators: Richard W. Gallagher, William M. Ford, Howard A. Johnston.

NEW YORK, N. Y.—Allenhust Auto Van & Express Co.; capital, $1,000. Incorporators: Charles Drewes, William Bohn, Johanne Bohn.

NEW YORK, N. Y.—Interboro Delivery Co., Inc.; capital, $1,000; auto vehicle delivery. Incorporators: Max Altschuler, Isidore Levine, Martin Radican.

NEW YORK, N. Y.—H. H. H. Tire & Mfg. Co.; capital, $50,000; to manufacture and deal in automobile tires. Incorporators: J. H. Dravle, Wm. C. Burroughs, John J. Coyle.

SAN ANTONIO, TEX.—International Automobile School; capital, $4,000; to instruct pupils to handle automobiles. Incorporators: Thomas P. Price, Gus Leroy, John A. Kerr.

WILMINGTON, DEL.—Pneumatic Rim & Tire Co.; capital, $200,000. Incorporator: Harry W. Davis.

CHANGES OF NAME AND CAPITAL

MILWAUKEE, WIS.—Milwaukee Motor Co.; capital increased from $250,000 to $800,000.

SANDUSKY, O.—Suspension Roller Bearing Co.; capital increased from $250,000 to $800,000.

SPLITDORF BRANCH OPENED—The Splitdorf Electrical Co., New York City, has opened an Atlanta, Ga., branch, situated at 8 Harris street. O. J. Rohde, who opened the Atlanta, Ga., branch, will shortly open a Newark, N. J. branch. Toronto, Ont., will shortly have a branch.

SMALL RESIGNS—A. H. Small has resigned from the Oakland-Wisconsin Motor Co., Milwaukee, Wis., to become Wisconsin field representative for the Marion Motor Car Co., with headquarters in the E. F. Sanger Co. garage, Milwaukee, representative of the Marion and Stearns.

METALLURGIQUE AGENTS BANKRUPT—W. C. and H. N. Allen, doing business as the Metallurgique Motor Co., selling agents for automobiles at 1876 Broadway, New York City, have filed a petition in bankruptcy with liabilities of $67,928 and assets $8,070, consisting of accounts $7,556, stock $150 and cash in bank $364.

TIMKEN ENLARGES N. Y. BRANCH—Increase of eastern business has made it necessary for the Timken Roller Bearing Co., and the Timken Detroit Axle Co., Detroit, Mich., to double the size of their New York City branch at Broadway and 68th street. They have leased the store next to their former place, throwing the whole into one large room.

FORD'S HAMILTON GARAGE OPENED—The new three-story garage of the Ford Motor Co., recently completed at 74 John street, north, Hamilton, Ont., was recently opened. The ground floor is used as a showroom, office and garage, while the two upper floors are devoted to repair work, and stock room. The garage is one of the largest in the province of Ontario.

NEW BOSCH SUPPLY STATIONS—The following Bosch supply stations have been selected by the Bosch Magneto Co., New York City, in their respective territories: Reed Motor Supply Co., St. Paul, Minn.; W. D. MacMillan, Jr., Wilmington, N. C.; Kinston Garage, Kinston, N. C.; Cuskaden Auto Supply Co., Atlantic City, N. J.; J. T. Cox, Penn Yan, N. Y.; Wichita Garage Co., Wichita, Kans.; The Auto Supply Co., Hutchinson, Kans.; and the Severin-Lumbard Tire & Supply Co., Oklahoma City, Okla.

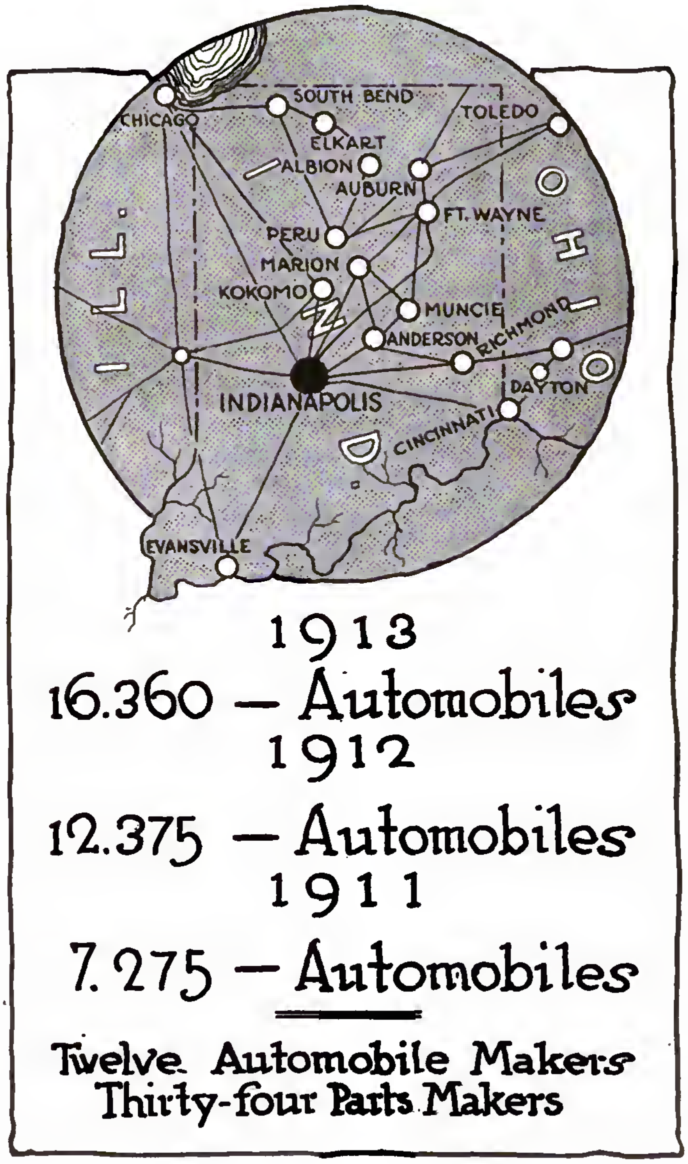
Vo. XXVIII NEW YORK—THURSDAY, MAY 29, 1913—CHICAGO No. 22

The AUTOMOBILE

Indianapolis

A City Where Pulling Together Has Brought Results

By L. V. Spencer



INDIANAPOLIS, first city of Indiana, enjoys the distinction of having within its boundaries more 18-karat boosters for the automobile than any one community in the United States. Its citizens have done more to make the whole subject of motoring and its allied topics widely discussed than have any other. They have promoted one automobile event after another until today, though not the largest city in the production of cars and their parts, the city is exceedingly well known by the automobile public as a manufacturing center.

Among cities of the United States, Indianapolis ranks third in the number of finished automobiles and their parts to be given to the world each year. Realizing that the Michigan city had several years the start of them in the matter of production, the Hoosiers set out to make their city equally prominent in the world of gasoline, sagaciously choosing other lines of endeavor which have netted big returns.

Just now the eyes of the motoring world are centered on Indiana's capital, for this week the cream of the world's speed creations will be piloted around the 2.5-mile Speedway in what bids fair to be the greatest 500-mile automobile race yet staged. Speed kings of this country and of Europe will vie for the rich prizes which the enterprise of a wide-awake city has posted as bait for the world's best. Fifty thousand dollars, which is to be split in ten pieces—the winner to get $20,000—has been offered and the Hoosiers feel that it is cheap, when the great amount of publicity which the city will reap and the thousands of spectators and motoring converts who will be drawn there for the race, are considered.

The Indianapolis Speedway project was announced in January, 1909, its plans originating with Carl G. Fisher, of Transcontinental Highway fame. An association was formed and the Speedway built at a cost of over $350,000 on the outskirts of the city, though being easy of access by two automobile roads, one traction line and two railroads. Its exact location is 4.5 miles northwest of the city.

The plot of ground on which the Speedway is located covers 328 acres and has on it forty-one buildings, including garages, aerodomes, hangars and the like. While the grand—

Panoramic view of part of the great Indianapolis Speedway, where the most daring and skilful racing drivers of Europe and America will strive

stands and boxes afford accommodations for 60,000 persons, the entire grounds will afford room for nearly 200,000 people. In addition, there is a parking space for 10,000 automobiles.

Since the holding of the International Sweepstakes races, the city has been the Mecca for motor car touring parties. One has to but examine the licenses carried by a part of the great collection of motor vehicles parked at one of these races to realize that nearly every state in the Union now has its motoring enthusiasts.

A word as to the actual construction of the track itself may be of interest. It has a surface of vitrified brick, 3,500,000 of these being required to cover the 2.5 miles. The turns, with a radius of 1,500 feet, are banked 16 feet, and a cement wall, 3 feet high and 11 inches thick, extends around the outer edge of these turns. Heavy wire mesh protects all stands from the track. Telephone lines connect all score-boards on the back stretch direct with timers' and judges' stands so that persons on any part of the track are told the standing of all participants in the events at any time. Thirty sets of telegraph instruments tell the outside world the progress of the speeding cars.

Yet the Speedway has not been the only agent Indianapolis has used to get into the automobile limelight. Through its Four-States tours, Coast-to-Coast runs, the activities of the Hoosier Motor Club, and the doings of an energetic Automobile Trade Association, the city has been placed upon the motoring map in big letters.

The idea of touring through four neighboring states each year was original with the city. The first tour of this sort was announced in April, 1911, and started July 16, covering a distance of 1,431.9 miles through the four states of Illinois, Iowa, Missouri and Indiana. The run was restricted to car manufacturers in Indiana and the object was purely a social and boosting affair. So much importance was attached to the affair that the then governor of Indiana, Thomas R. Marshall, pushed the button to start it. In this initial affair there were twenty-seven machines. The event is particularly notable from the fact that it was the first time in the history of the automobile industry that the automobile manufacturers of one state had banded together in such a movement.

The second of these tours, held last July, was made through the four states of Ohio, Kentucky, West Virginia and Indiana. Its mileage was 1,423. Thirty-three cars participated.

The 1913 tour, scheduled for July 1 to 25, will be replaced by a run to the Pacific Coast exclusively for Indiana manufacturers.

The Premier Coast-to-Coast run of 2 years ago attracted a great deal of attention. The participants were owners of these cars who started from Atlantic City on July 26, 1911, by dipping the wheels of their cars in the waves of the Atlantic. Twelve cars finished by dipping the wheels in the Pacific at Los Angeles on August 10, 1911.

It is just such events as these which are continually being originated and staged by a group of men who are pulling together to advance their city and to bring fame to their product.

There is a spirit of fellowship running through the long list of makers of cars and parts gathered together in the Hoosier city which is very evident to the outsider. There is a get-together-and-push atmosphere which is bound to work to the advantage of all concerned.

Another instance of the progressiveness of Indianapolis was the establishment last June of Speedway, the horseless city, a municipality unique in its ideas for thorough modernity both from the standpoint of the buildings, which it is planned to erect, and from the fact that it is to be horseless in every sense of the word. No horses will be permitted within the new town, the brain-child of Carl G. Fisher and James A. Allison. These men have long wanted to see a city built devoted entirely to the automobile industry which would be ideal in every respect. All dwellings must be of concrete. Factories are also required to be of concrete construction reinforced with steel and up to the latest architectural dictates. Cars and trucks only may traverse the streets.

The start of the second annual Four-States Tour, July 9, 1912, of the Indiana automobile manufacturers. It is

to lower the world's record in the great 500-mile race, May 30. The Speedway has done much to bring Indianapolis before the automobile world

During the early part of 1912 the two promoters of the project bought 1,000 acres of land, and after they had become thoroughly convinced of the feasibility of the plan of establishing a strictly motor car city it was made public to the world, attracting much attention.

The idea was not entirely a money-making proposition, but one which would further draw attention to Indianapolis and bring more power to it in a manufacturing way. Others have responded to the project and it has fast gained ground. The new plant of the Prest-O-Lite Co., consisting of twelve buildings, is located in Speedway, while half a dozen parts concerns and several motor car factories are to locate within its gates.

Industrially, Indianapolis may well be proud of its automobile and allied interests. There is a full dozen of the well-known motor car makers who have chosen the city for its many advantages. Situated at practically the center of population of the United States, it has an inexhaustible supply of cheap fuel, has competing steam and electric railroads in all directions, has plenty of labor of diversified character and plenty of room for this labor to live. In short, it has been characterized as the natural base from which to draw upon nearly all sources of raw materials. Its position is strategic as regards shipping to nearly all parts of the country.

Besides the twelve factories making motor vehicles there are thirty-four accessory and parts-making concerns identified with the city. This latter figure represents only those plants which are directly in the automobile class and devote either all or the greater part of their energies to the making of supplies and parts. It does not include such plants as those doing a more general business, such as the manufacture of bolts, nuts, screws and a hundred and one other articles which were just as necessary before the time of the motor vehicle as they are today when the making of such vehicles has grown to be one of the world's greatest industries. Were all of these added, the total would be swelled several fold.

The combined output of the dozen Indianapolis makers of all classes of motor vehicles for 1913 is approximately 16,400. This includes the electric output of the Waverley company—Indianapolis' only representative in the electric vehicle field—and the concerns making motor trucks. The total does not include the outputs of any concerns in the vicinity of the city, but exclusively those which may properly be regarded as belonging to Indianapolis.

During 1912 approximately 12,275 machines of all classes were produced by these same companies and for the year previous to this, 1911, about 11,000 machines were given to the world with the Indianapolis stamp on them.

It is difficult to estimate the outputs for the years previous to 1911 as no statistics of this nature were kept; however, an idea of the increase in production which has taken place since the early days of the industry in Indianapolis results from a search through old files.

These show that the 1906 output of the five factories then operating was approximately 2,100 machines, having an aggregate value of $4,105,000. This estimated production for that year did not include the then recently established American Motor Car Co. It included the number to be made by the Pope Motor Car Co., Waverley department; the National Motor Vehicle Co., the Premier Motor Mfg. Co., the Marion Motor Car Co. and Nordyke & Marmon, several of the city's leading firms.

Thus, in the making of motor cars the city has kept pace with the growth of the industry as a whole, having in 7 years increased its output of motor vehicles by 680 per cent.

Comparison of the total value of the motor vehicles produced by the Indianapolis concerns from year to year is rather difficult inasmuch as complete data along this line are not obtainable. However, from statistics received from five of the leading motor car concerns in Indianapolis it is shown that $9,461,500 worth of cars were made by them in 1912. All told the city's factories probably turned out machines to the value of $30,000,000 for this period. On the same basis, this year's output

largely to the energetic promotion of such affairs as this that Indianapolis owes her rapid rise as an automobile center should reach a market value close to $41,000,000, assuming that the price of the Indianapolis-made car averages $2,500.

It is apparent from these statistics that the Indianapolis motor car maker has not gone in for quantity production to any great extent. Nevertheless, the factories are large in size. The twelve have an aggregate floor space of approximately 1,714,000 square feet; add to this the floor space of the parts factories mentioned and the total reaches 5,000,000 square feet, 4,582,200 square feet, to be exact, according to the records at hand.

The working population of Indianapolis is well represented in the city's factories in the automobile industry. At the present time, 13,990 wage-earners are thus employed. Of this number, 6,650 earn their livelihood from the makers of cars, while the balance of 7,340 are paid by the producers of parts and accessories. There seems to be little opportunity for comparison with the motor car industry working population of previous years, since no such records are obtainable. However, the present population of Indianapolis is 267,000, while in 1900 it was 169,000, an increase of 98,000, or 58 per cent. It seems reasonable to assume that the number of automobile and parts factory wage-earners has increased about twice as fast, and we may, therefore, say that in a dozen years the industry has been responsible for the bringing to the city of at least 10,000 more men of the wage class, or one-tenth of the population gain. If every other industry could have done as well, the city's growth would have been unprecedented.

On the basis of the present population, the wage-earning class chargeable to the motor vehicle industry composes 5.2 per cent of the total persons in Indianapolis, the number in the car-making factories alone, 2.5 per cent., and in the parts and accessory plants, 2.8 per cent., as shown in the table:

1900 population	169,000	Percentage of present population	5.2
1913 population	267,000	Percentage of present population in car-making factories alone	2.5
Increase	98,000	Percentage of present population in parts and accessory factories alone	2.8
Increase—per cent.	58		
Total wage earners—automobile industry	13,990		

The automobile business in Indianapolis dates back to about the year 1900, although much experimenting had taken place before that year. Records show that an electric vehicle—the first built by the Waverley company, then known as the Indiana Bicycle Co.—was delivered to Charles Finlay Smith in January, 1907. In May, 1898, the Waverley was one of the four makes of electric vehicles exhibited at an electrical show held at the Madison Square Garden, New York. In 1903 the Waverley company built the first coupé body ever placed upon an electric vehicle chassis. Those prior to this had all been of the Stanhope design.

Among the gasoline car makers, Nordyke & Marmon are perhaps the oldest Indianapolis manufacturing concern, as it was established in 1851 as a machinery manufacturing business. In 1901 the company built its first motor car. In 1904 several more machines were made. A year later the Marmon was placed regularly upon the market.

The first of the Nationals came along about this time. The Premier Motor Mfg. Co. may also be numbered among the pioneers, it having been formed in 1902, when its first car was constructed. The American Motors Co., the originator of the underslung type of construction, began experimental work on its first underslung model in the summer of 1906.

The Marion Motor Car Co. was established in 1903. The present holding company took over the Marion interests on the first of last August. Later came the Cole Motor Car Co., which began making cars in June, 1909. The Empire Automobile Co., formerly the Empire Motor Car Co., was formed in 1909. The Motor Car Mfg. Co., maker of the Pathfinder, started business in 1911. The Ideal Motor Car Co., the name of which has recently been changed to the Stutz Motor Car Co., was established in 1911 also, and it was about this time that the Mais Motor Truck Co. came into being to manufacture a motor truck designed by a German engineer of that name. The Henderson Motor Car Co. was formed last year. Thus we have the following chronological table:

Waverley Co.	1897	Cole Motor Car Co.	1909
Nordyke & Marmon	1901	Empire Automobile Co.	1909
Premier Motor Mfg. Co.	1902	Motor Car Mfg. Co.	1911
Marion Motor Car Co.	1903	Stutz Motor Car Co.	1911
National Motor Vehicle Co.	1904	Mais Motor Truck Co.	1911
American Motors Co.	1906	Henderson Motor Car Co.	1912

In the parts and accessories making clan there are many names well known to every motorist. There is the Wheeler & Schebler concern which is the world's largest maker of carbureters, and which started in business in 1901. It employs from 500 to 800 men, has a floor space of 300,000 square feet and last year turned out 300,000 carbureters. The daily capacity of this plant is 4,000 carbureters.

The Prest-O-Lite Co. started in business in September, 1904, and has a floor area of 250,000 square feet, employing over 400 men.

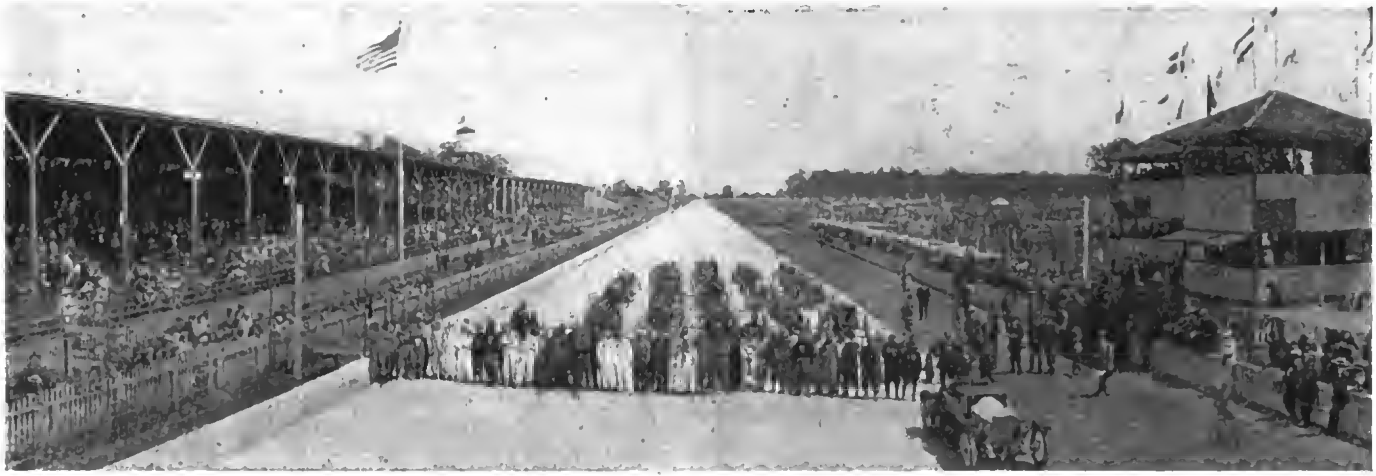
In the axle and transmission making field we find the Stutz Auto Parts Co. also claiming Indianapolis as its home. Maker of automobile machine parts is the Spacke Machine Co., formed in 1903 and now employing from 350 to 400 workmen on the average day.

High-speed chain makers are the Link-Belt Co., the Diamond Chain & Mfg. Co. and the American High Speed Chain Co., which furnish their product for automobile use as well as for other machinery constructions. The Keyless Lock Co., which recently moved into one of the most modern of bronze and aluminum foundries, is another of the many thriving concerns making specialties for the industry.

And so it goes on down the line. There is no end to the variety of motor car parts which bear the stamp of the Indianapolis-made.

These concerns and many others directly or indirectly connected with the automobile industry are operating on an enormous scale. Many others are not so large, but they are all thriving, each filling its niche in the great cycle of production.

A graphic representation of some of the most important factors which enabled Indianapolis to turn out 16,360 automobiles during 1912



Cars, drivers and mechanicians lined up before the start of the 500-mile race on the Indianapolis Speedway, May 30, 1912

Twenty-Nine Cars Ready for Big Race

ON Memorial Day, Friday, May 30, the third annual international Sweepstakes race will be staged at the Indianapolis Speedway. The entry list, which is limited to thirty cars, contains twenty-nine, and includes some of the fastest cars in the world driven by drivers of world-wide reputation. This classic speed event is indeed international in its scope, for no less than five nations are represented, including England, France, Germany, Italy and the United States.

In addition to the international flavor of this great speed event, this race will prove particularly strong for several of the following reasons: Among the eight foreign entries are the English Sunbeam and the French Peugeot which have been making such remarkable performances in Europe during the last 2 years. Another feature is that of the introduction of the Knight engine to American racing competition. Last, but not least, whereas in previous races cash prizes amounting to not more than $20,000 proved most attractive, the winner of this race, taking the value of trophies into consideration, has a good chance to win $35,000.

The qualifications for the race are that cars must not exceed 450 cubic inches piston displacement, must have a minimum weight of 1,600 pounds and shall be able to do 75 miles an hour. In last year's time trials all of the cars but one succeeded in making this speed and, barring accidents, in practice it is reasonable to expect that all of the twenty-nine cars entered this year will line up at the starting point.

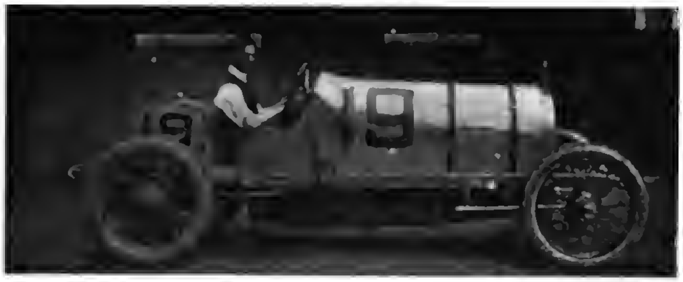
Considerable interest is being taken this year in the Sunbeam and Peugeot cars. The Sunbeam six-cylinder car now holds the world's records for 600 miles, 700 miles and 800 miles, all of which were made in 1911 on the Brooklands track at an average speed of a little more than 75 miles an hour. This car also holds the 7, 8, 9, 10 and 11-hour records, also established in 1911 on the Brooklands track. This car will have to increase its speed considerably, however, in order to win the Speedway race this year, for it is predicted that even greater speed than that of 78 miles per hour made in last year's race will be required to win this race of 1913.

SUMMARY OF CARS ENTERED IN 500-MILE RACE

No.	Car	Driver	Cylinders	Horsepower
1	Nyberg	H. Endicott	6	38.40
2	Stutz	Charles Merz	4	38.25
3	Stutz	G. Anderson	4	38.25
4	Keeton	Burman	4	42.20
5	Mason	Evans	4	30.65
6	Mason	Tower	4	30.65
7	Deltal	E. H. Delting	4	44.20
8	Stutz	Herr	4	38.25
9	Sunbeam	Guyot	6	29.45
10	Henderson	Knipper	4	29.00
12	Fox	Wilcox	4	36.15
15	Peugeot	Zuccarelli	4	29.00
16	Peugeot	Goux	4	29.00
17	Anel	Liesaw	4	32.40
18	Schacht	Jenkins	4	38.25
19	Mercer	Bragg	4	38.25
21	Mercer	De Palma	4	38.25
22	Mercer	Wishart	4	30.65
23	Mercedes-Knight	Pillette	4	16.92
24	Pennebaker	Pennebaker	4	42.20
25	Tulsa	Clark	4	36.15
26	Isotta-Fraschini	Grant	4	36.15
27	Isotta-Fraschini	Tetzlaff	4	36.15
28	Isotta-Fraschini	Trucco	4	36.15
29	Mercedes	Mulford	4	32.40
31	Case	Disbrow	4	42.20
32	Case	Nikrent	6	46.00
33	Case	Endicott	4	27.20
35	Mason	Will Haupt	4	29.00

As for the Peugeots, they have indeed everything in the way of prestige as a result of the world's records established by the Peugeot car driven by Boillot and Goux at Brooklands during the last few months. In April of this year several interesting records were established by Goux in a Peugeot car. The Talbot record for 50 miles in 29 minutes 2.5 seconds, which is equivalent to 103.3 miles per hour, was beaten by Goux's Peugeot which negotiated the 50 miles in 28 minutes 18.65 seconds, which is equivalent to 105.97 miles per hour. On the same day the Talbot records for 100 miles and the hour also were beaten. The Talbot's record of 100 miles in 57 minutes 49.38 seconds, or 103.76 miles per hour, was lowered by the Peugeot, which made the distance in 56 minutes 29.93 seconds, or 106.20 miles per hour.

These are indeed remarkable records, but it must be borne in mind that these records are only for 100 miles and were established on a track which is much easier on tires than the Indianapolis Speedway. Soon after these results were achieved at Brooklands these cars were forced to stop to make tire changes; and it is a well-known fact that numerous tire changes in the



Ralph De Palma in the special racing Mercer in which he will endeavor to overcome his frequent hard luck at Indianapolis this year by hard and consistent driving

George H. Clark mounted on his Tulsa racer, as he will appear in the annual 500-mile race on Memorial Day. The Tulsa is an Oklahoma car and is named after its native city

Spencer Wishart in his special Mercer ready for the 500-mile grind. Wishart's car differs from the other two Mercers in that the exhaust line is carried outside of the hood on the right side

Ralph Mulford in his big Mercedes all ready for the 500-mile contest, smiling his famous smile, which is unassuming in victory and undaunted in defeat

Don Herr and his Stutz, one of the team of three cars of this make which will strive to capture first place and as many other places as possible in the big Indianapolis classic

Indianapolis Speedway race of 500 miles are apt to prove fatal to almost any car as far as the grand prize is concerned.

This race will provide the first opportunity that the American public has had for judging the capabilities of the Knight engine when pitted against well-known exponents of the poppet-valve engine in a speed event, and it is needless to say that its performance will be watched with great interest. To add to the interest in this respect one of these cars, the Mercedes-Knight, has a four-cylinder engine, while the other is an exponent of the six-cylinder idea.

A substantial increase in the cash prizes offered for the first ten most successful cars in this event, has resulted in bringing together most of the best drivers in the world, and considering, both drivers and cars, it is very reasonable to believe that Joe Dawson's record of 78.7 miles per hour will be lowered and a speed of 79 or 80 miles per hour attained.

To the first man to cross the finishing line will be given the grand prize of $20,000, while the second man to cross the line will receive $10,000. For the next eight to follow him prizes of $5,000, $3,500, $3,000, $2,200, $1,800, $1,600, $1,500 and $1,400, respectively, will be given. In addition to these, the Motsinger company offers $1,000 to every driver who finishes within the first ten having a motor equipped with Motsinger carbureter. Findeisen & Kropf offer $1,000 in gold to the winner if his car is fitted with the Rayfield carbureter, and also the Rayfield cup, which is valued at $2,000; the Wheeler & Schebler Co. also offers $1,000 to the winner providing he uses the Schebler carbureter. As in previous years, the Bosch Magneto Co. will give three prizes of $500, $300 and $200 to the winners of first, second and third places, respectively, providing the cars are equipped with the Bosch magneto. Emil Grossman & Co. offer $500 to the winner, providing he uses Red-Head spark-plugs and the Hartford Suspension Co. will give prizes of $250, $150 and $100 to the winners of first, second and third places, respectively, providing Truffault-Hartford shock-absorbers are used on their cars. In addition to these cash prizes, the great Wheeler & Schebler cup, which is valued at more than $10,000, is offered for the first car to finish 400 miles. The Prest-O-Lite solid silver brick will be given to the first to finish 300 miles, and for the first to finish 200 miles the Remy Brassard will be given with a salary of $50 a week for 6 weeks. Altogether, it is possible for the winner of the race to come away with cash and trophies valued at more than $35,000.

Five Three-Car Teams

In this race there will be five teams of three cars each, which include the Stutz, Mason, Mercer, Isotta and Case, while the Peugeot has two entries. The Stutz team will be represented by a veteran Stutz driver in Gil Anderson and two excellent drivers in Merz and Herr, who have been recruited from the ranks of National pilots. Anderson has been handling racing cars since 1909, when he participated in the Crown Point and other races, but it was in the 500-mile race of 1911 that he earned a reputation for himself and the Stutz when he finished the 500 miles in the eleventh place. He also was a starter in the 500-mile race of 1912 in a Stutz car, so he should really know his car and the peculiarities of the track better than any other driver, for there are no others who have driven the same car in the two previous races.

Burman, who came into prominence in 1909 as a driver of the Buick cars and as winner of the Prest-O-Lite trophy at Indianapolis, afterwards became one of the best-known racing drivers in America as a result of his many remarkable performances with the Blitzen Benz. With this car he established and still holds all the A. A. A. records from the quarter mile, half mile kilometer and mile straightaways and speedways and the 1-mile for the dirt track.

Evans, who has never had an opportunity of driving a really fast car, nevertheless has a good record for consistency as a pilot for small cars and has won quite a number of competitions among the small car events.

Tower is another driven in Evans' class who has driven small cars for some time and came into prominence during the Beach races at Jacksonville in 1911, when he succeeded in winning three events.

Merz is well known on the Indianapolis Speedway, for it might be said that he was practically born and raised with it. He came into prominence in 1911 as a driver of the National car when he won a class event and was second in the free-for-all of the Panama-Pacific Race and Carnival at Oakland, Cal. Since then he has added to his laurels by coming in second in the Illinois Trophy race of 1911 and in winning the same race at Elgin in 1912. His team-mate, Herr, is also driving a Stutz in this year's event. He became famous as a racing driver in 1911 when he succeeded in piloting the victorious National in the Illinois Trophy event of the Elgin National Stock Chassis Road Race.

The Mercer team comprises three of the best racing drivers in America. De Palma is the most famous of this trio, having been the champion all-around-race driver of 1912 and being the holder of the 50-mile record for 1-mile circular dirt tracks and the 20-mile Class B Speedway record. He is one of the most sensational drivers in the world and perhaps the most capable in getting the maximum speed out of a car and holding it on the road at terrific speeds. In last year's 500-mile race, after leading up to the second from the last lap, he was forced to drop out of the competition as a result of engine trouble and he should be a very strong contender in this year's event.

Bragg, as winner of the Grand Prix in 1912, also occupies a prominent place among the most reputable drivers. He also has to his credit all of the American speedway records of from 2 to 5 miles, which were made in a Fiat at Los Angeles in 1910 and 1912.

Wishart, whose principal victory was at Fairmount Park, Philadelphia, in 1911, has won considerable prestige as a driver of Mercedes cars, having made most consistent performances with this machine in previous Speedway events and many other events throughout the country during the last 4 or 5 years. He also has to his credit the 75, 100 and 150-mile records for the 1-mile circular dirt track in a Mercer.

Isotta Has Formidable Team

The Isotta team also has two of the greatest drivers in America in Grant and Tetzlaff. Grant, who has twice driven the Alco car to victory in the Vanderbilt Cup Race, and who in the same car was second in the big race at Elgin in 1911, is recognized as one of the most competent drivers in the world and his performance in this year's 500-mile race will be watched with considerable interest.

Tetzlaff has never had anything but hard luck in his Middle West and Eastern competitions, but in the Far West he reigns supreme. He was winner of the most important event at Santa Monica in 1910 and also at Tacoma in 1912, while three events went to his credit at the Motordrome in Los Angeles in 1911. Tetzlaff also holds the 25, 50, 75, 100, 150, 200 and 250-mile American speedway records, regardless of class, the first three of these having been made in the Lozier and the last four in the Fiat.

The Case is well represented. Disbrow has been a most consistent driver for several years, having won many small events, the most important of which was at Philadelphia in 1911. Disbrow has many records to his credit. Among these are the straightway free-for-all records, regardless of class, for 150, 200, 250 and 300 miles and the 1-hour race which were made in a special car at Jacksonville in 1911, and the 3, 4 and 5-mile records for the 1-mile circular dirt track, which were made in a Simplex at Cleveland. Disbrow also won four events at Jacksonville, Fla., and four more at Old Orchard, Me., in 1911.

"Bill" Endicott has been a consistent small car pilot for a number of years. His principal victories include one event at the Los Angeles Motordrome in 1911 and the Wisconsin Trophy, which he captured in Milwaukee in 1912.

Nikrent also has won several prominent victories at Bakers-

Louis Disbrow and mechanician on his chain-driven Case as they will appear in the big race at Indianapolis on Memorial Day. Note how closely the chassis is stripped to reduce weight

The Henderson contingent. Left to right, they are Harry Goetz, the team manager; Frank Jones, mechanician and relief driver; Billy Knipper, driver, and R. P. Henderson, vice-president of the Henderson Motor Car Co.

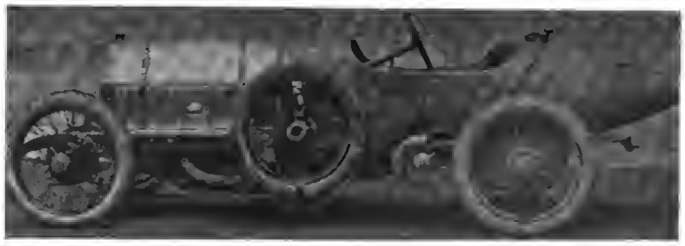
Harry Endicott in the Nyberg special racer which will be his mount in the big Indianapolis race. This is one of the three sixes entered in the contest



One of the three Isottas entered in the race. The drivers nominated for these cars are Harry Grant, Teddy Tetzlaff and Trucco, the latter from the factory in Italy

The three cars comprising the Case team are somewhat different in mechanical details. They are stripped very closely

field, Cal., Santa Monica, Los Angeles and at the Los Angeles Motordrome in 1911.

Aside from the American team drivers, Mulford is perhaps the most prominent among the single entries. Mulford became famous in 1910 when he won the Elgin National and Fairmount Park races and was second in an important event at Philadelphia. He added considerably to his laurels in 1911 when he won the Vanderbilt and was second in the Elgin National. His chief performance in 1912, however, was the second place which he won in the Elgin National Road Race.

Billy Knipper came into prominence when he won the Cobe trophy race at Crownpoint, Ind., in 1909 in a Chalmers car and again when he won the small-car race at Savannah in 1910.

Wilcox became prominent as pilot of a National car and has had considerable experience on the Indianapolis Speedway, particularly in the 500-mile race as he competed in both of the previous ones. In 1911 Wilcox added considerably to his laurels at the Beach Races in Jacksonville, Fla., in which he won five events, and at the Los Angeles Motordrome, where he carried off the first prize for four events. Wilcox also holds the 1 and 5-mile record in the 301 to 450 cubic inch class.

Jenkins is a well-known driver of small cars, having made consistent performances in many of the country's important events during the last 4 years. He has driven in both of the previous 500-mile races at Indianapolis and is credited with the first place in one event at Fernbank Dam, Cincinnati, O., in 1911.

If car quality is any criterion of a race meet, the Memorial Day 500-mile international race will be the most closely-fought battle of speed kings America has witnessed. In spite of the fact motors are smaller this year than formerly has been the rule at the Speedway on account of the piston displacement limitation of 450 cubic inches, it is a safe prediction that a faster pace will be set than ever before. Not alone are the cars lighter, which to an extent makes up for the difference in cylinder dimensions, but, judging from construction and design, the engines will develop more power in proportion to their cylinder volume, and more of that power will be used in turning the rear wheels. Unless indications are at fault there are going to be fewer stops for tire changes and the cars are going to run longer without halting for fresh supplies of fuel and oil.

High engine speeds are the rule; such speeds as 2,800 and 2,900 revolutions per minute are common talk among the railbirds and in the racing camps. Greater attention is being paid to lessening the wind resistance; streamline bodies and small head-on area seem to be as much the ideal as great motor power. More attention has been paid to distributing the weight of the various parts of the car in such a way that skidding and bouncing over the brick track will be reduced to a minimum and thus tire wear reduced.

So far as the motors themselves are concerned, the American public will have an opportunity to see a greater variety of engine designs than ever has been offered. Not only will there be a

*Nos. 15 and 16 have valves in head at angle each side. No. 35 has L head. **Double valves.

The three Stutz cars form a strong team. They are stripped as cleanly as possible to minimize weight and wind resistance

competition between the poppet-valve and the sleeve-valve designs, but among the poppet-valve designs there will be a great variety. In addition to the familiar L and T-head and the still-older valve-in-the-head constructions, there appear two valve arrangements new to the Speedway, Dusenberg's combination of horizontal valves in the side and in the head, which made its début at Elgin last year, and the diagonal arrangement of the valves in the cylinder head of the two Peugeots, which are to make their initial American appearance.

Knight-type motors appear in Pilette's Mercedes-Knight and in the Pennebaker Special. The Belgian's mount is the smallest car in the race, having a displacement of only 250 cubic inches. The sleeve valves have two inlet and two exhaust ports, each 2.125 by .5 inches. The car weighs 2,380 pounds with driver and mechanic and full tanks. Pilette relies on continuous running rather than high speed to make a showing in the race. He believes that he will be able to run the entire distance without a stop except for tires. This is on account of his exceptionally low consumption of fuel. He finds that at the speed he will endeavor to average he gets 21 miles per gallon of gasoline and the 40 gallons he carries will take him 720 miles. He believes his 10 gallons of oil will carry him the full distance. He does not attempt to account for this economy. His combination of light weight and wire wheels, together with the fact that the weight is evenly distributed over the wheels he believes will reduce tire wear to a minimum. The car has a special oil tank on the dash, feeding to the rear end. A novel feature is the use of a V-shaped wooden shield on the front axle to cut the wind. Other features are a sharp nose and a V-radiator.

A combination of old favorites appears in No. 20, Ralph Mulford driving the Mercedes. This is a chain-drive car with 108-inch wheelbase. It weighs about 2,850 pounds, the motor has valves in the head. The brake connections are cables.

Pennebaker's motor is much larger than the others, having within 7 inches of the limit in displacement. It weighs about 2,500 pounds empty and carries the same quantity of supplies as does the other. The motor weighs 812 pounds.

The three Isottas to be piloted by Tetzlaff, Grant and the Italian Trucco, are alike so far as motor construction is concerned. They are unique in that there are two exhaust and two inlet valves in each cylinder operated by a camshaft which is above the cylinder heads. Pistons are of pressed steel and are very light. Knipper's Henderson and the three Mason cars have the Dusenberg design of motor which did so well at Elgin and Milwaukee last year. In this the valves extend horizontally into the side of the cylinder, the push rods and rocker arms working in and out instead of up and down. These cars have both pump and thermal cooling, water being taken from the bottom of the radiator in two separate pipes, one to the radiator and the other for the thermal system. The gasoline tank used by the Masons is part of the frame to prevent the breaking of connections from vibration. The Masons have turtle backs.

Bob Burman at the wheel of the Keeton entry

Showing the wind cutting lines of the speedy Sunbeam

Exhaust side of the engine on Burman's Keeton

Massive exhaust manifold of De Palma's Mercedes

The Peugeots have two camshafts on top of the cylinders driven by vertical shaft and worm from the crankshaft. The valves are in the head, but are set into the cylinder diagonally. Valves are in duplicate throughout and the seats are on the under side of the cylinder casting, so that the valves are closed when they are pushed up. Oil is forced into the cylinders at a pressure of 30 pounds per square inch. The pressure employed in most of the American racers is in the neighborhood of 2 pounds. Pistons are cut from solid blocks of steel.

The car having the most features of interest to American eyes is the English Sunbeam. The motor is one of the three sixes in the race and is of the L-head type cast in blocks of three. Though all the valves are on the left side of the cylinder, the carbureter is on the right, the inlet manifold passing between the two cylinder castings. One of the novel features is the method of cooling the oil through a series of 1.5-inch copper tubes arranged outside of the body and running from the motor to the tail. The oiling system is a circulating one under a pressure of 25 pounds per square inch. After the oil has been used in the motor it is sent through these cooling tubes before it is returned. Another evidence of thoughtfulness is the way the waste of water from a steaming radiator is prevented. Instead of allowing the steam to shoot out the overflow pipe, the latter is attached to a coil of small copper tubing in the form of a spiral which acts as a condenser, returning the evaporation in the form of water to the radiator. Pistons are bored from a solid steel block and are very light.

The three Mercedes to be driven by De Palma, Bragg and Wishart have very much the same features that characterized this car last year. The motor is of the T-head type cast in pairs. The transverse shaft in front of the motor and carrying the pump and magneto is a feature still, but the chain timing-gear drive is supplanted by a spur gear with skewed teeth. The pistons are cast steel.

Disbrow and Nikrent's two four-cylinder Cases are similar in size and make-up. This involves a T-head motor cast in pairs and a double chain drive. There is a difference in wheelbase, Nikrent's being 4 inches longer than Disbrow's. The six-cylinder Case which Endicott is to pilot is an L-head motor with valves in the head. Two sets of exhaust valves are used. This car has shaft drive. Both Nikrent and Endicott have their balance well worked out so far as weight distribution between front and rear wheels is concerned. The four weighs only 150 pounds more in the rear than in the front, while there is only 40 pounds difference between front and rear on the six. Steel forged pistons are used on all three Cases.

Nyberg One of the Sixes

Harry Endicott's Nyberg is the other of the three six-cylinder cars entered in the race. The car has an L-head motor cast in pairs. The valves are comparatively small, being 1.875 inches in diameter and .375-inch lift. Endicott has gone in for reducing wind resistance, giving the body a streamline effect by a sharp nose and tail and a flaring shield in front of the steering wheel. The nose has fins in front of the radiator to direct the air upon it.

Burman's Keeton is one of the spectacular cars in looks as well as speed. The oddity in looks is due to the radiator location back of the motor. The motor is covered with the sloping European type of hood, which is simply a screen. The engine has T-head cylinders cast in pairs. Burman has a special brace for the steering column, illustrated in one of the sketches on this page. A vertical rod is bolted to the side frame member and attached to the column by a T. Another brace of strap steel runs from that point to the transmission. It is curved and carries the shaft of the speedometer.

The three Stutzes driven by Merz, Anderson and Herr are alike in every respect so far as can be told from the outside appearance. The motors at least are the same size, 4.814 by 5.5 inches. The Stutz company does not care to have all the details published at this time. It may be stated, however, that the motors are T-head, cast in pairs. The cars can carry 25 gallons of gasoline and 14 gallons of oil. The gear ratio is 2.25-1. There has been little attention paid to getting streamline body effects.

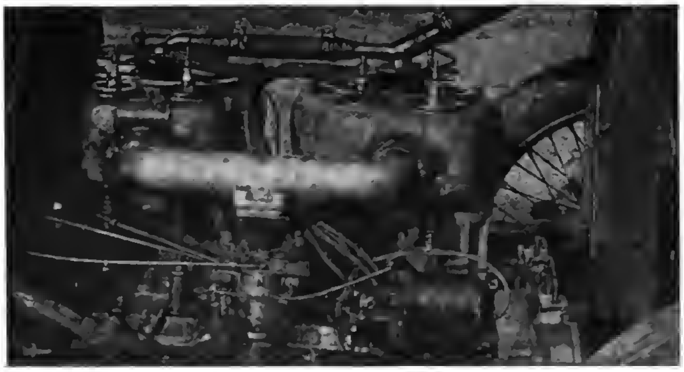
Novel Features in Fox

Wilcox's mount, the Fox Special, was built by Frank Fox, of Indianapolis, and has some novel features. The motor is a valve-in-the-head design made with 2.25-inch valves made of chrome vanadium steel lifting 9-16 inch. Empty there is 16 pounds more weight over the front wheels than over the rear, but with load the rear wheels carry 240 pounds more than the front. The wheelbase is 104.5 inches. Special pains have been taken in the balance, but Fox relies more on his own special spring suspension to prevent tire wear.

Liesaw's Anel gets its cognomen from the name Lena spelled backwards. It has a familiar type of valve-in-the-head motor with the spark-plugs stuck in the side. This car is unique in two respects. So far as known at this time it is the only one that will attempt the race without differential action and the only one not having an aluminum crankcase. Liesaw finds the bronze crankcase holds up better. There is no exhaust manifold, the exhaust being led from each cylinder directly through the hood to the air. The steering column is supported in a manner similar to Burman's, and illustrated herewith.

The Schacht which Jenkins is to pilot is the only car which has appeared so far with the sheet metal guards on the wheels which were so common last year during the tryouts.

Clark's Tulsa is an Oklahoma entry and takes the name of its home city. It has a T-head motor with the cylinders cast in pairs. The car weighs 2150 empty and has wire wheels.



Intake side of the Tulsa motor. Note the absence of fan

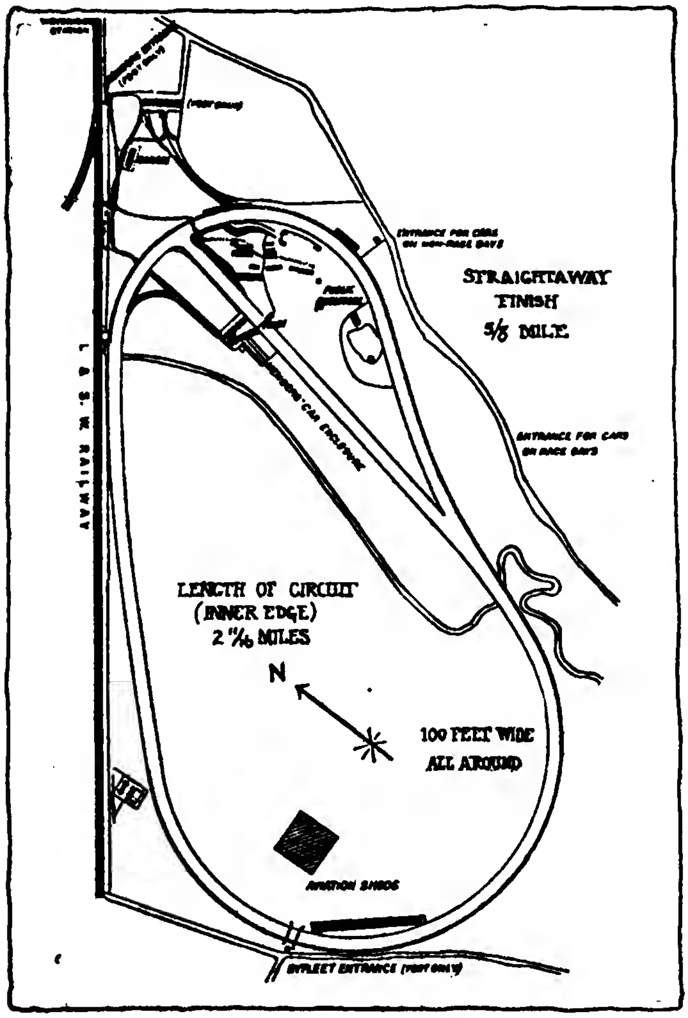
Brooklands Is World's Fastest Speedway

THE Brooklands motor course, which is situated at the Weybridge Station of the London & Southwestern Railway, in England, is the fastest speedway in the world, its superiority over the Indianapolis Speedway from a speed-producing standpoint being obtained by means of the design and construction of the course as regards the greater radius of its curves and its more efficient banking. The track surface is of concrete laid to a depth of from 6 to 8 inches.

The Brooklands Speedway was constructed during 1906 and the spring of 1907 by H. F. Locke King, the owner both of the track and of the property on which it stands. It is the first of the really great speedways designed particularly for automobile competition, and the aim for constructing the track was not only to give English manufacturers an opportunity of competing in motor races on equal terms with their rivals on the Continent, but also to provide a testing ground whereon the efficiency as well as the speed of cars could be improved.

Until the Brooklands track was opened Continental European manufacturers had an enormous advantage over their English rivals, owing to the fact that important road races were held yearly on the Continent and nothing of a similar nature was possible in England. Now all this is changed. Brooklands track is always available, whereas Continental motor races can only be held once, or at most, twice a year. The advantages which English manufacturers have gained thereby have been so marked that projects for the construction of similar tracks are on foot both in France and Germany.



Plan view of the grounds at Brooklands track

The Brooklands track is somewhat of the shape of a pear; the complete circuit is 2 miles 1,350 yards. Across one corner is an internal portion of the course known as the straight which leads from the circuit of the track to the finishing lines and official buildings, the latter being situated on a space known as the paddock. Between the straight and the northeastern corner of the track are the inclosures, which, being on a natural hill, enable the spectators to obtain a magnificent view of the track. In these inclosures are erected covered stands for viewing the races, in addition to lunch rooms, refreshment rooms, cloak rooms, etc., all of which are capable of accommodating a very large number of spectators.

As for the curves of the Brooklands track, there are only two when the Straight is avoided, both of which are of a greater radius than those of the Indianapolis Speedway. The sharpest curve on the northern end being struck at a radius of 1,000 feet, while the mean radius of the longer curve is 1,550 feet. This is one of the chief reasons why the Brooklands track is faster than the Indianapolis Speedway, which really has four curves having a radius of 840 feet. The curves of this track have been scientifically banked so that even at speeds of 100 miles an hour a car driven at the proper height on the banking has all four wheels pressing equally on the track and there is no tendency to skid. One circuit of the track on the center line gives a distance of 2 miles 1,350 yards. One circuit at 10 feet from the inner edge gives a distance of 2 miles 1,263 yards. The width of the track is 100 feet. The length of the level Finishing Straight is 991 yards and the maximum height of banking on shorter curve is 28 feet 8 inches.

Track Measured for Testing Work

To enable manufacturers to carry out careful tests of their cars the track has been most accurately measured and various points marked thereon, so that with the assistance of any of the staff manufacturers can, if they wish, take accurate note of the distance traversed and for their own purposes ascertain the speeds of their cars, fuel consumption and any other details they wish to observe. A special test hill has also been constructed on accurate gradient; and with the combination of the track and the hill practically every detail of a motor car can be carefully worked out. The average gradient of the test hill is nearly 1 in 5 whilst the maximum gradient is 1 in 4.

In addition to the scientific work which goes on at Brooklands and the regular testing, the sporting side is by no means overlooked and regular race meetings held at the track are now a feature in the sporting calendar. During 1913 five large race meetings will be held in addition to numerous small ones inaugurated by county motor and cycle clubs.

Specifications of the Brooklands Speedway Construction

Length of circuit once round with finishing straight, 3.25 miles.
Length of circuit once round with finishing straight, 3.25 miles.
Mean radius of shorter curve, 1,000 feet.
Mean radius of longer curve, 1,550 feet.
Length of level finishing straight, .625 mile.
Length of level in one circuit, 2 miles.
Up gradient of the approach to shorter curve, 1 in 30.
Down gradient from shorter curve, 1 in 25.
Width of course, 100 feet.
Maximum height of bank on shorter curve, 28 feet 8 inches.
Maximum height of bank on longer curve, 2 feet 10 inches.
Number of bays or stopping places for cars, seven.

Brooklands was officially opened in June, 1907, and until near the end of 1909 it was devoted almost exclusively to motor car and motorcycle tests and competitions.

Indianapolis Speedway as 500-Mile Course

THE Indianapolis Speedway was constructed in the spring of 1909 by the Indianapolis Speedway Co., headed by C. G. Fisher, A. C. Newby, F. H. Wheeler and J. A. Allison and with P. J. Andrews of New York as construction engineer. The first races upon it were run in August of that year, while the track was still in a rather incomplete condition. As a result of the premature opening, however, several regrettable accidents occurred and fault was found with the surface of the track. Immediately after the races, therefore, the original taroid macadam surface was covered with vitrified brick, and these improvements were completed for a meet held in the fall of the same year.

The course of the Indianapolis Speedway is 2.5 miles long, 50 feet wide on the straight stretches, 60 feet wide on the curves, and is located on a plot of ground 1.5 miles long, .5 mile wide, containing 320 acres. The straight stretches are 3,301 feet long, while the ends are 660 feet long. The curves are each a quarter of a circle of 840 feet radius on the course line or 90 degrees of a 6 degree 49 foot 30-inch curve, no easement curves or spirals being used. The curves are banked to an angle of 16 degrees, 40 inches in cross-section for 50 feet of their width, the remaining 10 feet of width being banked to an angle of 36 degrees, 40 inches.

The approaches and releases to and from the bank curves are limited to a 2 per cent. grade in sections parallel with the measured course line and the maximum variation from a level plane at the course line is a 2 per cent. grade. The straight stretches are given a pitch of .8 inch in 50 feet toward the infield for drainage, thus presenting a fine flat track. In constructing this speedway, after being properly graded the whole course was resurfaced and rolled with a 15-ton three-wheel steam roller until the surface presented a smooth, firm and uniform plane. Two inches of thick gravel was then spread uniformly over the entire surface and rolled with a 15-ton roller. This was followed by a 2-inch layer of crushed limestone rolled with an 8-ton tandem roller, over which was poured 2 gallons of taroid to the square yard. This surface was then overcast with ½-inch crushed stone chips filling the voids between the larger size stone and given another coat of taroid of a lower melting point than the first part. Over this was spread a thick layer of crushed stone from .5 inch to dust in size and given a final rolling with a 3-ton tandem steam roller.

3,200,000 Paving Bricks Required

This surface, which presented the original idea, did not prove to be satisfactory, and the idea of paving over this surface with brick was evolved and carried out. In preceding with the brick paving it was decided to accept the specifications of the National Paving Brick Manufacturers' Association, and 3,200,000 pressed paving bricks were ordered for the purpose.

Two reinforced concrete bridges were built to support the track over a stream running diagonally across the southwest corner of the grounds. These bridges are 30 feet wide and 90 feet long and of a permanent character.

The main grandstand, a commodious covered structure, seats approximately 10,000. Ranging around the south turn are thirteen miniature grandstands intended for private parties, each of which will hold twenty-eight people. Then in about the middle of the south turn is another big stand, the bleachers, which will hold 4,200 more. The main grandstand is 82 feet wide and 500 feet long and there are two bleachers, one 500 by 60 feet and the other one 350 by 65 feet.

Three miles of tight board fence 8 feet high, surmounted with barb wire surrounds the grounds, the posts being set in concrete. There are 7 miles of wire fence in the infield and around the track and 1.5 miles of 8-foot picket fence, two suspension bridges for foot traffic cross the track, giving egress from the infield during the races. A truss bridge for vehicles also is provided which affords entrance and exit to and from the infield.

Boillot, in Peugeot, Star at Le Mans

Covers 5 Kilometers in 1 Minute 56 2/5 Seconds—Average Speed 96 Miles per Hour—Two Americans Entered in Meet

PARIS, May 14—Georges Boillot, piloting the racing Peugeot with which Goux set up world's records at Brooklands recently, was the star performer at the Le Mans Whitsuntide meeting. The 5 kilometers straightaway was covered in 1 minute 56 2/5 seconds, being at the rate of 96 miles an hour. No other car came anywhere near the Peugeot's time. In the kilometer hill climb, with a flying start, over an average gradient of 5 per cent, Boillot's time was 35 2/5 seconds, being at the rate of 62.8 miles an hour. America was represented in this meeting by two Buicks, one running as a racer, the other as a touring car. In the racing section the Buick was fastest in its class, putting up 2:58 2/5 for the 5 kilometers (3.1 miles) and 48 seconds for the kilometer hill climb. The touring Buick, driven by Repusseau, showed 3:26 for the 5 kilometers and 56 seconds for the kilometer hill climb. The best time made in the touring sections, irrespective of size, was 2:36 1/5 for the 5 kilometers and 44 4/5 for the hill climb. These times were made by a new model Rolland-Pilain carrying six passengers. For the kilometer an Isotta-Fraschini tied with the Rolland.

5 kilometers—3.1 miles—Racers

Grand Rapids Run Sanctioned

GRAND RAPIDS, MICH., May 24—Official sanction No. 577 has been allotted by the contest board of the A. A. A. for the second annual reliability run for Grand Rapids automobile dealers and private owners, promoted by The Grand Rapids *Herald* and given under the auspices of the Grand Rapids Automobile Club.

The tour will occupy the dates of July 21 to July 25, inclusive. The route will be the central highway to Mackinaw, returning via the Lake Michigan coast semi-boulevard trail. Each day's drive will be a hammering run, early into night controls, each of which will be in some one of Michigan's famous resort cities, with a whole afternoon and evening at historic Mackinaw. The only portion of the route to be twice traversed will be the main street in Petoskey.

Wolseley Wins Canadian Climb

HAMILTON, ONT., May 24—*Special Telegram*—The first hill-climbing contest ever held in Canada took place on Saturday, Dominion Day. It was won by A. Sharp, of Toronto, in a Wolseley car in 2 minutes and 42 seconds. Other cars of 35 horsepower and over scoring victories included the Hudson, Stearns, Overland and Russell.

Plan 6 Day Tour into Virginia

PHILADELPHIA, PA., May 24—Starting next Thursday morning, the Automobile Club of Delaware County will conduct a 6-day tour of Virginia. The start will be made from Newtown Square and participants will be picked up *en route* through Paoli and

Pierron, in Rolland-Pilain, made fastest touring car time

Georges Boillot making 96 miles an hour in his Peugeot

Baby Peugeot car which took part in Le Mans meet

Buick car on a straightaway in the Le Mans meeting

Downingtown, with a noon stop at Lancaster, Gettysburg being the objective point for the first day. Various points of interest in Virginia will be visited on the second, third and fourth days, the return trip being scheduled to start on Monday.

—

Sixteen Cars for Indiana-Pacific

INDIANAPOLIS, IND., May 24—The participants of the Indiana-Pacific tour which will last 33 days and cover 3,549.1 miles, will travel through eight states, following the route shown on the map herewith. Starting from Indianapolis on July 1, they will pass through St. Louis, Kansas City, Colorado Springs, Denver, Salt Lake City, Goldfield, Sacramento and San Francisco, to arrive in Los Angeles on August 2. There will be no path-finding tour, but an official pilot will travel in advance of the tourists, marking the trail. So far sixteen entries have been received.

—

INDIANAPOLIS, IND., May 26—The Indiana Automobile Manufacturers' Association has received two entries from Apperson Brothers, Kokomo, for the Indiana-to-the-Pacific tour, which starts from Indianapolis on July 1. Elmer and Edgar Apperson have announced they will alternate driving one of the Apperson entries. The total number of entries for the tour is now eighteen. The route of the tour has been announced and is shown on the accompanying map.

—

NEW YORK CITY, May 26—The L. I. A. C. will hold, on May 30, a run from its home in Brooklyn to the Edgewood Inn, Greenwich, Conn., which must be done in a specified time. Penalization will be for lateness, and the least penalty in combination with a secret mileage over which the trip is to be made will decide the winner of the Frank H. Newcomb trophy. Every contestant will have a chance of deciding whether he will make the trip over a short road slowly, or quickly over a long one.

—

WASHINGTON, D. C., May 26—The newly organized Washington Motorists' Association will give its first run Memorial Day, to Hagerstown, Md. The event is to be a free-for-all affair, with no rules or restrictions, and it is expected at least 100 members of the association will take part.

—

$2,500,000 Cement for Transcontinental

INDIANAPOLIS, IND., May 26—The Ocean-to-Ocean Highway movement, projected by Carl G. Fisher and James A. Allison, has received a material boost by the offer of the Association of American Portland Cement Manufacturers to furnish cement valued at approximately $2,500,000 for the road. The offer is conditioned on the road being of concrete construction.

This brings the total subscriptions to the movement up to about $5,000,000, or approximately half of the $10,000,000 the promoters have undertaken to raise for the purchase of material. It is believed the offer will bring renewed interest in the project.

—

France to Allow $6,800,000 for Roads

PARIS, FRANCE, May 14.—Probably a credit of $6,800,000 will be allowed this year for the upkeep of the 38,337 kilometers of national highway existing in France. This will represent an increase of $400,000, compared with a year ago, and will be an allowance of $243.6 per mile per annum for maintenance only. For 1914 it is proposed to grant the sum of $7,200,000 for the national highways, this being at the rate of $302.25 per mile per annum. These figures deal only with the national highways of France, which have a total length of 23,831 miles, and are entirely under the control of the central government. The three other classes of roads, which are more or less under local control, have a mileage of 339,867, giving a total for all classes of made roads in France of 363,698 miles.

Recent events have shown that the credit for the upkeep of French national highways is insufficient, not having kept pace with the increase of traffic and particularly automobile traffic. Even the progressive increases made since 1910 are hardly sufficient to cover the increasing wear and tear. A proposal is now before Parliament to make a special allowance of $1,600,000 for the reconstruction of roads in most urgent need of repair. With a grant of this proportion and the projected increase for maintenance expenses the roads can be got back to their original perfect condition.

Members of the American Society of Automobile Engineers and of the English Institute of Automobile Engineers just before setting out from the steamship pier for the Hotel McAlpin

S. A. E. Enthusiastically Greets English Engineers

Members of American Automobile Engineering Society at Pier To Meet British Delegation—Many Social Activities

NEW YORK CITY, May 27—The party of twenty-five English automobile engineers arrived here yesterday at 6:30 p. m. and were met by a large gathering of members of the Society of Automobile Engineers who had gathered in this city to greet their British guests. Three rousing cheers hailed the party as they made their way down the gangplank and the waiting automobiles whirled them to their quarters at the McAlpin Hotel.

After a rest of about an hour the male members of the party were conducted to Healy's restaurant, where a beefsteak dinner awaited them in the Jungle Room. Here the members of the party were initiated into the intricacies of the American beefsteak dinner which had been discussed frequently during the voyage. It is even stated that the members of the party persuaded the captain to closely approach the record day's passage of the Minnewaska in order to get the party to New York in time for the affair. At the conclusion of the dinner speeches of welcome were made by Toastmaster Anglada, President Marmon, P. D. Wagner, H. M. Lloyd and C. W. Spicer, the members of the New York committee and the general committee to which Messrs. Brown, Joy, Clarkson and Wheeler responded with an expression of appreciation for their hearty welcome.

The party assembled again at the McAlpin Hotel at 8:30 this morning and in spite of a drizzling rain and raw wind enjoyed an automobile trip around the city. During the forenoon the Woolworth Building was visited as well as the Battery, Brooklyn, the East River bridges, the Aquarium and the service plants in Long Island City. At the conclusion of the morning's run the party assembled at the Automobile Club of America where a buffet luncheon was served. Owing to the bad weather the baseball game had to be omitted from the program and trips to local points of interest were made instead. The New York City Fire Department has promised a drill to exhibit the working of the Metropolitan apparatus.

The program calls for a stay in New York until 9:25 tomorrow morning when the party will board the train for Pittsburgh. Two special cars have been set aside for their use and these will be sidetracked during the stay at Pittsburgh and Indianapolis.

Tire Makers Oppose Tariff

NEW YORK CITY, May 24—The tire manufacturers have filed a brief with the Senate committee under whose consideration is the Underwood tariff objecting to the proposed reduction of duty on guttapercha or india rubber, from 35 to 10 per cent. ad valorem. The makers state that the duty should be at least 25 per cent. The reasons given for the objection are the high labor cost in this country and the unconditional competition among the tire makers. It is also stated that if the reduction goes through the Goodrich company, having a factory in France, would be able to produce enormous quantities of tires for the American market, paying for cheaper labor in France; so that it would be possible for this company by the use of its French factory to "beat the Akron manufacturers off the face of the earth," according to the language of the protest.

Electric Men Object to Truck Fee Raise

BOSTON, MASS., May 24—The New England section of the Electric Vehicle Association of America, the Electric Motor Car Club of Boston and the Electric Light Companies of Massachusetts held a joint meeting here on May 20 and 21 at which the general and local problems facing the electric-car maker, dealer and user were taken up. The attendance was large, and besides listening to a series of papers, the visitors held an outing at Relay House, Bass Point, Nahant, situated on the north shore of Massachusetts Bay. The plant of the General Electric Co., West Lynn, was visited.

The following resolution was passed by the members of the three bodies present at the meeting:

RESOLVED: That the passage of any bill arbitrarily increasing the registration fees on motor trucks would be injurious to the industry as a whole, would tend to retard the industrial development of natural resources and the manufacturing growth of this state, and would seriously restrict commercial progress. Such action would be contrary to the traditional spirit of progress which has always distinguished this commonwealth and its great and general court;

RESOLVED: That such a discriminating tax would be an unfair burden upon a growing industry which is assisting to promote commerce and improve fundamental conditions in the commonwealth's industrial life;

RESOLVED: Should it be found necessary to secure additional funds for building and preserving the state highways, that a scientific investigation of actual traffic conditions should be made, which we believe would show that horse-drawn wagons and trucks tend to destroy the highways by reason of the sharp steel shoes of the horses and the narrow steel tires to a much greater degree than the broad yielding tires of the motor truck and that fees should be proportionately charged on all vehicles using the highways.

Truck Club Members Discuss Docks

NEW YORK CITY, May 26—The Motor Truck Club of this city held its monthly meeting here on May 21, when the questions of trucks and the New York docks were discussed. Steps were proposed to influence the construction of new docks, now under way, which are to be erected between Forty-second and Fifty-ninth streets, so that there be better provisions for trucks than there are at the old docks now in use.

Majority Vote To Settle Accessory Show

M. & A. M. May Hold Separate Exhibition

NEW YORK CITY, May 27—The question whether the interest of the members of the Motor and Accessory Manufacturers would be best preserved by participating in the 1914 show at Grand Central Palace or by conducting a distinct and separate show at the Madison Square Garden—an option for which has been taken by the M. and A. M.—busied the members present at today's meeting of the board of directors. If the majority of members, among whom a vote is now being arranged, are in favor of a separate show in the Garden, the latter will be held at the same time with the Palace show of the Automobile Chamber of Commerce. In case of a separate show manufacturers of motorcycles and parts of the same will be offered a chance to share in the Garden show. However, no matter what may be the vote of the majority of the members, and the consequent decision upon the course to be taken, the situation in Chicago will remain as before, so far as can be seen now, the M. and A. M. expecting to participate in the show to be held in the Coliseum, Annex and Third Regiment Armory.

This is by far the most important question now faced by the members of the M. and A. M. The body includes now a number of new members who became such since the 1913 show, after which William S. Sweet, general manager, made a trip to the West.

Light and Heating Strike Over

NIAGARA FALLS, N. Y., May 27—The strike in the plant here of the United States Light & Heating Co., which started on March 2, was settled last Friday afternoon, and yesterday mornthe 1,700 strikers returned to their places in the North End concern. The settlement was reached when Superintendent Engel of the plant agreed to reinstate all men who had been discharged because they were affiliated with labor organizations and those who voluntarily went on strike three weeks ago. Before the strike the company offered its employees a 9-hour day with 10 hours pay or a 10 per cent. increase in wages for a 10-hour work day. The men decided to return to work with a 9-hour day with the same wages they formerly received for 10 hours. No new men will be employed until all the strikers have been reinstated.

Germans Buy 300 Cars in 8 Months

BERLIN, May 16—During the 8 months ending with May 1, 1913, there were 300 American cars, worth $280,000, sold in Germany. During the corresponding period a year ago only eighty-nine cars which, however, aggregated a considerably higher value were disposed of in the empire. Similar advances of the American trade are reported from other Continental countries and Great Britain, which during the year ended with April imported 2,000 cars more than during the preceding 12 months.

Bennett General Manager for Willys

TOLEDO, O., May 24—John North Willys, president of the Willys-Overland Co., the Garford Co., the Gramm Motor Truck Co. and a number of other concerns, has announced the appointment of George W. Bennett, vice-president of the concerns named, as their general manager.

This step of John N. Willys shows the great confidence he has in Mr. Bennett as well as the appreciation of the latter's work in the past. Indications are that Mr. Bennett will now have a larger hand in the affairs of the company than ever before.

Before affiliating with the Overland interests, Mr. Bennett had been on the sales organizations of the White and Rambler concerns.

Treasury's Drawback Allowances to Makers

WASHINGTON, D. C., May 25—The customs division of the treasury department has been busy during the past week issuing drawback regulations to motor car companies. One prescribes that drawback of duties shall be allowed under section 25 of the tariff act of August 5, 1909, on motor cars designated as model T, manufactured by the Ford Motor Co., of Detroit, with the use of imported aluminum and Scandinavian brake lining. The drawback allowance is not to exceed the quantities of imported materials appearing in the exported cars, as shown by the maker's sworn statement, filed with the collector of customs at Detroit.

A similar regulation has been issued allowing drawbacks to the Abbott Motor Car Co., of Detroit, on motor cars and motor car real axles manufactured by that company with the use of imported ball bearings. The regulations stipulate that the allowance shall not exceed the number of imported ball bearings appearing in the exported cars or axles as shown by the manufacturers' sworn statement, also filed with the collector of customs at Detroit.

Drawback allowances will also be given the Stegeman Motor Car Co., of Milwaukee, on exportations of motor trucks manufactured by that company with the use of imported magnetos and ball bearings.

The American Ever Ready Co. is to receive drawback allowances on exportations of Ever Ready ignition batteries.

Chicago Subway Garage Held Up

CHICAGO, ILL., May 27—*Special Telegram*—At the meeting of the Chicago South Park Board held last week the commissioners rejected the plans for the proposed subway garage under Grant Park, on the ground that such a structure was not feasible. What action Mayor Harrison, who is sponsor for the underground garage plan, will now take is not known, although it is reported that he will request a reconsideration. Unless the park commissioners adopt the plan, it will have to be abandoned, as they alone have jurisdiction over Grant Park, which is the property of the state and not of the municipality.

A group of S. A. E. and I. A. E. members leaving the pier

Beefsteak Dinner at Healy's, where S. A. E. and I. A. E. made merry Monday evening

Cannot Fix Retail Price

Federal Supreme Court Deems the Payment of Maker's Price Enough Protection

WASHINGTON, D. C., May 26—*Special Telegram*—One of the most important patent decisions handed down by the United States Supreme Court in many years was rendered today in the case of Bauer Chemical Co. and others against James O'Donnell, a druggist of this city. While the case primarily relates to a proprietary medical preparation, it affects many patent owners, including those in the motor-car-supply trade. Justice Day delivered the court's decision, which was decided by a five to four vote.

"Is this an attempt to restrict prices within the statutory patent right to vend?" the court said was the principal question. "To vend means to sell, of course. The difference between the copyright and patent right is that the latter gives the right to use patented articles. The thing really gives the right to use patented articles. The thing really done here is to sell, not to use, this article. When an article is sold to a jobber, the manufacturer receives his price and all the protection and immunity of the patent law to which he is entitled. He cannot further restrict the retail price at which it is to be sold to the public.

"The case is brought within that line of cases in which this court from the beginning has held that a patentee has parted with a patented machine by passing title to a purchaser."

Oldfield Patent Bill to Come Up

WASHINGTON, D. C., May 25—Insisting upon a reform in the patent laws, Congressman Oldfield, of Arkansas, is scheduled to remain at the head of the house committee on patents and when organized the committee will begin immediate consideration of the Oldfield patent bill. The bill will provide a complete revision of the existing laws relating to patents and will seek to prevent the monopolistic control of patents.

One of the objects of the measure will be to circumvent the recent supreme court decision in the Dick mimeograph case, which gives the patentee of the article control over its use and selling price. As the bill will be radical in its nature it is expected the committee will give exhaustive hearings.

Grant a New Detroit Cycle Car

DETROIT, MICH., May 24—The Grant Motor Co. has been incorporated in this city for $100,000 to manufacture a small type of car of the cyclecar class. The officers of the company are George D. Grant, president; C. A. Grant, vice-president and sales manager; David Shaw, secretary and treasurer; G. F. Salzman, factory manager, and J. M. Howe, engineer.

The car, the first model of which may be seen on the streets of Detroit now, is to be known as the Grant. It is really a miniature motor car, having seating accommodations for two people side by side. It has a 20-horsepower, four-cycle motor and a cone clutch, left drive and center control. Wire wheels are used. The tread is 56 inches and the wheelbase 90 inches. The total weight of the machine is 930 pounds and it is designed to sell at $495.

As yet no factory location has been decided upon, but the new company is very active in getting started, and will be in a position to manufacture before long.

SEATTLE, WASH., May 23.—A plant for the manufacture and distribution of the Schram car, a Seattle-made automobile, is to be established within a few miles of the city in the near future. F. A. Mitchell is secretary of the company, the other officers of which are: F. J. Carver, Seattle, president; A. J. Schram, vice-president of the California Motor Car Co., maker of the Sunset car, designing engineer, and W. R. McClelland, treasurer. The concern is incorporated at Olympia with a capital of $500,000.

The Schram will be built in four and six-cylinder models. The six, which will sell on the Coast for $2,200, will have a wheelbase of 135 to 140 inches. The four-cylinder, in touring car and roadster models, will have a wheelbase of 129 inches and will sell at $1,500.

Automobile Securities Quotations

QUOTATIONS of automobile securities on the New York Stock Exchange were subject to irregular changes this week, but due to a strong undercurrent the majority of changes was of an upward nature. However, all changes were very small, being caused by the varying relation of supply and demand.

problems now faced by the companies they stand for, as well as by the users of electric passenger and commercial cars

Motz Tire Is Infringement

Cadwell Patent Anticipates It—Searchlight Cannot Refill Prest-O-Lite Tanks

NEW YORK CITY, May 26—Motz clincher rubber tires, made by the Motz Clincher Tire & Rubber Co., which is owned by the Goodyear Tire & Rubber Co., are an infringement upon the patent rights of Edwin B. Cadwell, the number of the patent being 887,997. This decision was rendered by Justice J. M. Mayer of the U. S. District Court, Southern District of New York, in a suit of Edwin E. Cadwell, Frank P. Johnston, Frank M. Ashley and the Swinehart Clincher Tire & Rubber Co., against the Rapid Safety Filter Co., of New York.

The most important passages of the decision read as follows:

Ordered, adjudged and decreed as follows:

That the letters patent of the United States dated May 19th, 1908, numbered 887,997, issued to Edwin B. Cadwell, of Detroit, Michigan, assignor of one-third to Frank M. Ashley and one-third to Frank P. Johnston (the said Edwin B. Cadwell, Frank P. Johnston and Frank M. Ashley being complainants herein), being the letters patent mentioned and described in the bill of complaint, are good and valid in law as respects claims numbers 7, 9, 10, 13, 14 and 15 thereof.

That the defendant, The Rapid Safety Filter Co., of New York, is a corporation organized and existing under the laws of the State of New York, having its principal place of business in the Southern District of New York.

That the defendant, The Rapid Safety Filter Co., of New York, subsequent to the date of issue of said letters patent numbered 887,997 and prior to the commencement of this action infringed upon claims numbered 7, 9, 10, 13, 14 and 15 of said letters patent numbered 887,997, and upon the exclusive rights of the complainants under the same, by the use, without right or license, of four rubber tires, and which said tires were substantially as described in said letters patent and the claims thereof above enumerated.

That the defendant, The Rapid Safety Filter Co., of New York, in transporting its filters used an automobile equipped with the said four rubber tires; and which said four rubber tires were manufactured by The Motz Clincher Tire & Rubber Co., of Akron, Ohio, and known as the Motz tires.

That a perpetual injunction issue out of and under the seal of this court, enjoining and restraining the defendant, The Rapid Safety Filter Co., of New York, its officers, directors, associates, attorneys, agents, salesmen, clerks, servants and workmen, and each of them, from in any manner, either directly or indirectly, using or causing to be used the said four rubber tires or any of them on any automobile or otherwise or any other similar tires containing and embodying the invention described in the aforesaid claims numbers 7, 9, 10, 13, 14 and 15 of letters patent numbered 887,997.

Motions Denied in Hartford Suit

NEW YORK CITY, May 26—The motion of the Hartford Suspension Co., in U. S. District Court, Southern District of New York, praying for an injunction against the Concrete Bumper Co., has been denied by Justice Lacombe, as was the motion of the defendant to dismiss the bill of complaint. The latter refers to the making of bumpers, the bars of which are filled with concrete. The answers will be filed in the near future.

Abbott Reorganization Completed

DETROIT, MICH., May 27—*Special Telegram*—The complete reorganization of the Abbott Motor Co. by which the control of the business virtually comes into the hands of its creditors has now been effected. Nearly all of the concern's indebtedness is represented in the new directorate which provides a long extension of time on outstanding indebtedness and gives additional money for the proper carrying out of the business.

In addition to the officers announced in THE AUTOMOBILE for last week, A. E. Shaefer, formerly of the Ohio Motor Car Co., vice-president and treasurer, Wade Millis has been made secretary, completing the management. The Board of Directors consists of nine, all except two of the members of which have been named. In addition to the officers, A. W. Lewis, of the Timken company; H. I. Mallory, Weston Mott company; G. W. Rogers, of the Goodyear company, and H. M. Preston, who was heavily interested in the Olds company, have been chosen.

Not to Refill Presto-O-Lite Tanks

INDIANAPOLIS, IND., May 26—In the United States court here last week, Judge Albert B. Anderson handed down a decision in the suit brought by the Prest-O-Lite Co. against the Searchlight Gas Co., in which an injunction to prevent the refilling of Prest-O-Lite Co. by the Searchlight company, together with an accounting and damages, was asked.

Judge Anderson issued a permanent injunction, enjoining the Searchlight company from refilling the Prest-O-Lite tanks before the Prest-O-Lite name plate has been removed. He denied the accounting and damages that were asked.

Market Changes of the Week

SHARP breaks accompanying sluggish markets occurred this week in Bessemer and open-hearth steels, the former dropping $2 per ton and the latter $2.50. Lead was more active and firmer, rising $0.05 per hundred pounds. Tin experienced a rise of $0.18 per hundred pounds, in anticipation of higher rates after the Banca sale in Holland, when 2,500 tons will be offered there. The principal development of interest in the petroleum markets was the announcement of further chartering for exports of petroleum to Norway and Sweden. About 15,000 barrels will be shipped. Both petroleums from the Pennsylvania and Kansas wells remained constant holding their former prices of $2.50 and $0.88 per barrel, respectively. The cotton-seed oil market again promptly responded to the strength in lard with a slight gain of $0.07 per barrel in price. A moderate demand is reported from the dealers in automobile scrap rubber, the market is steadily holding its own and future trading has a promising outlook.

California Has Model Law

Raises Speed Limit from 20 to 30 Miles Per Hour and Overrules All Local Ordinances

SAN FRANCISCO, CAL., May 23.—The new motor bill passed by the California legislature is the most advanced and comprehensive automobile statute that has been enacted. The bill in general follows the draft of the measure prepared by the Automobile Club of Southern California and except for the amendment providing for the collection of an annual license fee based upon horsepower, it is in all essentials the one fathered by the club.

It also raises the speed limit on country roads from 20 to 30 miles per hour and unifies the speed laws of the various towns and cities within the State by establishing minimum speed limits which cannot be abrogated by local ordinances.

The state has also decided that the annual license fees will be as follows:

For cars of less than 20 horsepower	$5
Between 20 and 30 horsepower	10
Between 30 and 40 horsepower	15
Between 40 and 50 horsepower	20
Between 50 and 60 horsepower	25

Annual Licensing Proposed for D. C.

WASHINGTON, D. C., May 26—*Special Telegram*—Annual registration of all motor vehicles, the payment of an annual license fee and the repeal of the wheel tax on automobiles are provided for in a bill framed to regulate the licensing, registration and operation of motor vehicles in the District of Columbia, forwarded by the commissioners to Congress today with a request for its early enactment.

The object of this bill is to vest in the commissioners complete authority to regulate automobile traffic in the district. Section 5 provides for the repeal of all existing laws and regulations on the subject and authorizes the commissioners to make all the necessary regulation anew, to impose all necessary license fees and penalties for violations of the regulations, and to prosecute such violations. It is further provided that all existing motor licenses shall be made to expire December 31, 1913. On and after January 1, 1914, owners of motor vehicles shall be required to obtain new licenses based upon regulations to be adopted by the commissioners. The existing rules governing the operation of motor vehicles in the district are included in special acts of Congress regulations promulgated by the commissioners under special authority delegated to them by Congress and regulations made under their general police authority. The commissioners' views regarding the proposed legislation are set forth in the following letter addressed to Senator Smith, chairman of the Senate Committee on the District of Columbia:

"The commissioners believe that the present speed limits fixed by an act of Congress should be amended and the matter of speed should be left to them to adjust by regulation as the necessities of the case may require. They believe that there should be an annual registration or license fee for motor vehicles and that the existing act of Congress which has been construed as requiring the fee to be paid but once should be repealed. They believe that the imposition of an annual wheel tax against motor vehicles should be repealed. There is no necessity for such a wheel tax, if the proper annual registration of license tax is imposed. At present the owner of a motor vehicle has to pay a registration or license fee, an annual wheel tax and an annual personal tax on a motor vehicle as personal property. The whole matter of the proper annual license fee to be paid should, in the commissioners' judgment, be under their control.

"The commissioners believe it more advisable for Congress to delegate to them the authority of handling the question of automobile traffic than that it should be handled directly by Congress. Conditions change, especially as to the matter of speed and traffic regulations, and if conditions should arise which would warrant changes, the commissioners are not free to bring about the change without the delay incident to a modification in the law by Congress.

"If the commissioners handled the matter, such changes could readily be made by a change in a regulation. The matter is one coming within the general police power, such as has been delegated to the commissioners by Congress and there seems to be no reason why motor vehicles should be exempt from the general police power of the commissioners as is now the case.

"It would be the intention of the commissioners in exercising the authority proposed to be conferred upon them by the bill, to prepare and adopt usual and reasonable regulations such as are in force in other jurisdictions governing the matter of automobile registration and traffic. Under such general authority they would have the power to enter into reciprocal relations with other jurisdictions."

HARRISBURG, PA., May 26—The Grabe Pennsylvania state tax bill, providing for a special fund for the improvement of streets and roads in boroughs and townships, was passed by the house this week. The bill directs the state authorities to collect a one-mill tax for the street and road improvement on personal property, capital stock, bonds of corporations, gross earnings of corporations, bankers, brokers and foreign insurance companies and also on capital stock of brewing companies.

The money thus raised, estimated between $5,000,000 and $6,000,000, is to be kept by the state as a separate fund and to be expended by the state highway commissioner, the distribution of money to be made on a mileage basis of the streets and roads of each borough and township. The bill provides that its provisions become effective December 1, this year, and the distributions are to start April 1, 1915.

Idiotic Tire Bill in Illinois House

NEW YORK CITY, May 27.—A bill is now before the two houses of the Illinois legislature which compares even with such measures as the New York tire-dating bill like a criminal of many years' experience does with a new-born orphan boy.

This product of human genius (?) reads as follows:

Be it enacted by the People of the State of Illinois, represented in General Assembly: That it shall be unlawful, within this state, for any person, firm or corporation to sell, resell or otherwise dispose of any tire to be used on any motor vehicle, unless the same shall have been properly stamped, clearly and legibly, and in the English language, with a die, and in such manner, designate thereon, the date when such tire was originally manufactured or made (or when, if such be the condition, such tire was repaired, with the date of such repair, and whether the same is a new or second-hand tire, and whether or not the same has previously been used) and such tire (when new) shall have a tag pasted thereon, showing the ingredient, composite and component parts thereof.

Violation is to be punished with a penalty of from $50 to $200 for each offense. The bill in this form is No. 217 of the Senate, introduced by Mr. Manny. With the passages in parentheses obliterated, it was introduced by Assemblyman Sullivan as House Bill No. 673.

In this bill, tires are looked upon with as much spirit of national economy as pure food, although it were undoubtedly more to the point, if such measures would be proposed with reference to shoes, hats, toothbrushes, etc., etc.—even though the matter would remain just as ridiculous. So much for the repair history. As to the tag showing the composition of the tire, this is most absurd, as no sane man would seriously expect a manufacturer to proffer his experience, which is a principal part of his business capital, to anyone buying a tire for a few dollars. But, however foolish a measure the bill, it will not escape the eyes of motorists and doubtless will be nipped in the bud.

Night Lights in Connecticut

HARTFORD, CONN., May 26—A bill calling for lights on all light spring vehicles after sunset was called up this week by House Chairman Macdonald in the state legislature. He moved concurrence with the senate amendment which changed the time of lighting from one-half hour after sunset to one hour after sunrise, which was adopted. The Macdonald amendment excepted highways lighted all night by municipalities. This was passed and Mr. Macdonald moved the adoption of the bill. The bill was carried 125 to 54.

Pennsylvania Fights Light Bill

HARRISBURG, PA., May 26—The Pennsylvania Motor Federation is fighting for the senate bill which requires all vehicles to display a light at night. The bill has passed the senate, but is being held up by the public roads committee of the house. This would mean that all carriages, wagons, carts, etc., on the roads at night would have to be equipped at night with lamps. With this law in effect collisions would probably cease.

Nutmeg State Wants No Bridges

HARTFORD, CONN., May 26.—A bill has been introduced in the Connecticut legislature passage of which would put the entire cost of highway bridges on the state. It was pointed out that such a measure once it became effective would let the trolley companies out of their share of cost. An amendment to the act calling upon the state to build and maintain all highway bridges up to 40 foot span was denounced as revolutionary. The state could not stand the expense, it was pointed out.

Makes 87 m.p.h. on Benzol

English Driver Proves Practicability of New Fuel for High Speeds at Brooklands

LONDON, ENG., May 23—One of the most convincing tests on benzol for high speed work was carried out this week on the famous Brooklands racing track, when Louis Coatalen successfully attempted new records in the class to which his car belonged. The 12-16-horsepower Sunbeam car which he drove, running on benzol instead of gasoline, has a bore of 80 millimeters and stroke of 120 millimeters, which is 30 millimeters shorter in stroke than is the case with standard cars. In fact, interest will be aroused when it is mentioned that the engine fitted into this car is identical to those that were installed in the Sunbeam-engined boats that competed at Monte Carlo, and it was owing to the success attained in marine work that Mr. Coatalen decided to see what results could be obtained with benzol on the track. New records were created in the Brooklands cubic capacity class C, wherein the volume must not exceed 150 cubic inches, or 2,458 cubic centimeters contents, so that the Sunbeam engine was well within its class range, being only 2,431 cubic centimeters in volume, or 45 cubic centimeters less than the limit allowed.

For the flying half-mile this car attained a speed of 86.96 miles an hour, and from this distance all class records up to ten laps of the track, or 28 miles, were broken. The ten laps were covered at a speed of 82.5 miles an hour. There is therefore no further room for doubt concerning the efficiency of benzol, for as compared with the previous records set up in this class with engines running on petrol, we find that the records for the ten laps was only 72.46 miles per hour, compared with the new figures of 82.5 miles an hour, and for the half mile the previous best stood at 75 miles per hour, and the old figures were created by cars which had a larger cubic capacity volume than the Sunbeam engine. One point that must not be overlooked is that when starting on the ten lap journey in the first lap, from a standing start, progress was slow, but as soon as the engine warmed to its work it gave a speed of 84 miles an hour.

Fear Corner in Benzol

LONDON, ENG., May 20.—Things are developing rapidly with regard to the use of benzol in automobiles in England. The one possibility to be guarded against today is that benzol may be cornered. In fact, there are rumors already of a combine to control it. The suggestion has been made by *The Motor* that the state step in and prevent anything in the nature of trust methods being adopted in handling this new fuel.

The whole motor community is agog with excitement on the subject, particularly as tests with the coal spirit result in surprising results. The engine pulls better with it and a greater mileage per gallon is obtained with it. At Birchenwood in Staffordshire a huge plant for producing motor spirit and all the other by-products has been in full swing for some time, but the bulk of the spirit is contracted for abroad, and the coke produced after all the products are obtained fetches a good price—and is in great demand for metallurgical purposes. The interesting point about this and other plants is that coal of quite indifferent quality can be treated and will produce very good spirit. If plants were erected at other collieries like that at Birchenwood or on the lines of the del Monte low-temperature system our prodnction of home spirit would supply all our requirements without the necessity of importing a single gallon per annum, and we should be using up coal slack or dust and coals of so poor a quality that they are a drug on the market. For instance, cannel coal is a coal that was once used for gas-making in the old days before the use of incandescent mantles. To-day that coal which is too rich in gas cannot be used by the gas companies, so it is running to waste. By either the Birchenwood or the del Monte process this coal yields 20 gallons of excellent spirit to the ton, but the residue is not so good as a burning fuel as that produced by some other coals. Cannel is a slatey-looking coal and is hopeless-looking stuff as a fuel, yet is rich in oil, and what is most interesting is that the supply available for distillation purposes is enormous.

It will be gathered from all this that, providing our collieries erect the plant for treating coal at the pit mouth, by extracting all its valuable properties, which under the wholly wasteful usage hitherto existing have been entirely lost, Great Britain can supply herself at home with all the crude oil and motor spirit she requires, thus rendering her independent of outside supplies, and making her position secure in time of war when her imported supplies might conceivably be cut off.

The position at the moment of writing is an extremely interesting one, and the possibilities are great. I do not think there is any doubt about the ultimate development of the scheme on the broadest possible lines, and I feel quite confident that Great Britain is on the eve of one of the most remarkable industrial revolutions yet recorded in her history.

Put concisely, the scheme is to trap the wastage that can be seen belching from every factory chimney stack and household dwelling in the country and turn it into power and profitable materials, and at the end of it all to produce smokeless fuel. That is the ideal, and we are now on the very eve of its realization.

The reader may ask what about the possibility of the gasoline trust cutting prices when faced with competition of the serious nature portended. Well, that is exactly what I have in mind when I say we must call in the state. This is no small matter of individual interests. It is vital to the country that it shall have its liquid fuel unfettered by any mind of rigging combine. It has been figured out on some processes that the motor spirit can be given away and still the other products will produce a huge profit.

Recently the plant at Birchenwood has increased its output of benzol to over 3 gallons to the ton of coal.

An important development of the home-produced fuel problem is to be found in the fact that our leading daily newspaper, *The Times*, has now fallen in line and in one of its recent engineering supplements deals very fully and very capably with the whole subject of motor fuel production from coal, confirming and emphasizing all that has been published in *The Motor* since it started its advocacy of benzol. This is a very significant step.

With regard to gasoline the situation is unchanged. Prices are unchanged, but the oil controllers are viewing the growing demand for benzol with some signs of uneasiness. At present there are difficulties in obtaining the English spirit in many parts of the kingdom, but as soon as we can create sufficient demand at home to hold up the exports, supply and demand will adjust themselves. The gasoline people are wonderfully organized here as regards distribution, but the benzol business is for the present quite hopelessly handicapped in that direction. There are restrictions about distribution in bulk—the 2-gallon can is the only legalized form—which place it at a very serious disadvantage. Shell spirit can be purchased in 2-gallon red tins in every small village throughout the kingdom.

Ohioans Against Double Tax Law

COLUMBUS, O., May 27—Both of the warring factions in the Ohio State Automobile Association were brought together and all differences were buried at the annual meeting of the organization held at Columbus May 24. The meeting was harmonious in every respect and was attended by representatives from seventeen auto clubs in the Buckeye State. In all thirty-seven delegates were present representing about 4,000 members of all of the clubs.

One of the most important actions was the adoption of a resolution instructing the new executive committee to take legal steps to have the new Warnes double-taxation law declared unconstitutional.

Officers were elected as follows: President, C. C. Janes, Columbus; first vice-president, G. E. Mentell, Springfield; second vice-president, W. L. Faunce, Youngstown; third vice-president, W. L. Winning, Dayton; secretary, L. M. Browne, Columbus, and treasurer, J. H. Allen, Kenton. The president was empowered to name all standing committees.

AUSTIN, TEXAS, May 24—In order to show the need of legislation governing the registration of automobiles and with a view of having a measure of this character passed at the special session of the law making body which is to be held in July, statistics have been collected showing that in 1912 there were 10,000 automobiles registered in Texas. This shows an increase of 65 per cent. over the registration in 1911.

The Indianapolis Cars

IN the descriptions and specifications of the cars to contest in the 500-mile race at Indianapolis this week the observer cannot but note the reduction in motor sizes as compared with a year ago, the maximum limit for this season being 450 cubic inches as compared with 600 a year ago. The result of this reduction cannot be stated until after the race but the management is to be congratulated in reducing the maximum of last year by 25 per cent. in that it is in keeping with present day trends of automobile construction. From announcements already made by manufacturers, the motors of 1914 will average lower in horsepower than those of 1913. There is a general reduction in bore and stroke. Racing has taught its lessons in Europe and America and will continue to teach them and if Friday's race of this week, under conditions practically parallel to those of a year ago, can demonstrate speeds as fast as made by the winner last year then there is done genuine good. The days of bulk are passing, the days of efficiency are at hand. The small motor is showing its superiority in test and in economy.

This year France is combining fuel economy with speed in its important road races It is to be hoped that next year Indianapolis will add the fuel economy feature and also the oil feature. By so doing the management will be conferring a favor on the industry at large in this country.

A Three-Fold Contest

THE recent Catskill reliability contest, in which reliability on the road, hill-climbing reliability and economy of gasoline consumption were taken into consideration as factors in determining the grand winner, has opened the way for developing increased interest in competitions of this nature. Some years ago the individual reliability contest was an attractive field of battle for the manufacturer. The hill-climb was equally interesting. The economy contest never became popular but, whenever held, developed not a little interest It lacked the spectacular features of the hill-climb and the continued interest of the long-distance reliability. Combining the three proved particularly popular in the contest referred to and will be a success in future.

The three-in-one contest meets the requirements of the automobile owner better than any other type of contest. It develops economy and reliability.

The most satisfactory method of properly proportioning the importance of each with regards to the other must receive consideration. On a basis of 1,000 points 600 were given for reliability; 200 for hill-climbing and 200 for economy in the test referred to. It is debatable if this proportion should not be slightly altered, giving 250 for economy and 150 for hill-climbing.

It will not be too difficult to accurately gauge the relative economy of the contestants because under the formula generally used, which takes into consideration the vehicle weight with load and the amount of gasoline consumed, it is possible to put all of the contestants into a common division and give the small car an equal standing with a large car, the reasoning in connection with this being that the lighter weight vehicle will have a smaller motor, proportional to its load, than the larger vehicle. In years past it has been generally argued that the economy run decided on these two factors has generally favored the heavier vehicle and placed a premium on weight. It is a question of open debate whether this has actually been the case or not, and if it can be proven that such is the case then the formula should be altered so as to place a discount on weight and a premium on that nicety of proportion between motor capacity and load carried so that the motor will work at its point of maximum efficiency most of the time.

A new scheme of reckoning must be established for hill-climbs; in other words a formula must be introduced the same as in fuel tests. Some years ago a formula was used in determining the winner in the Algonquin Hill-Climb at Chicago. This formula took into consideration the weight of the car, the piston displacement of the motor in cubic inches, and the length of time to climb the hill computed in seconds. The result was that all of the vehicles competed in a common class so far as determining their standing was concerned. It is possible to use some similar formula in the new three-in-one contest, and the results so obtained would be immeasurably more satisfactory than those obtained on a time basis only.

It is to be hoped that more of these three-way contests will be staged. It is excellent advertisement to the industry. It gives an opportunity of renewing that interest in contests of this nature which is so desired to-day.

The Ideal Garage for Electric Cars

From a Paper Read by H. M. Martin Before the Electric Vehicle Association of America, at the Meeting Held Tuesday Evening, May 27.

SIMPLICITY and cleanliness are the electric's prominent characteristics, and these ideas can be exemplified in an electric garage which will be complete in every detail, and yet be in strong contrast to the more elaborate equipment and larger space necessary to garage and repair gasoline cars.

The location of the garage should be central with regard to the places of business of its customers. Since customers are not usually promised in advance, other conditions assume greater importance. If possible, it should be on a well-paved street near a main artery of travel—and here we strike the first necessity for compromise since property of this description will probably be too expensive.

The number of floors of the building will be determined by a compromise between the cost of additional vertical construction with all that that implies, elevators, etc. Particularly if there are many floors, the elevators (of which there must be at least two) will be of as high a speed as good judgment will allow, because on the elevators' speed will depend the number of cars that can be accommodated.

Electric Elevator Control

Electric control from the car should, of course, be employed instead of the usual hand rope. The electric control precludes the possibility of starting the elevator by anyone not on the platform itself. Automatic gates will prevent, nine times out of ten, the serious accident of having a car fall down the shaft.

It is preferable to have no posts to interfere with the free movement of cars, though to leave them out will add materially to the initial expense and make the floors thicker and the whole building higher. If posts must be used, let them be spaced with regard to the number and sizes of cars that are planned to stand between them.

Concrete floors should be painted with a preparation giving them a smooth surface which is easily cleaned and saves the concrete from wear and gritty dust from rising. These floors should be pitched slightly from the center line down to the side walls, both ways, with gutters formed in the concrete along the walls so that washing may be done, if necessary, without moving the cars.

Lighting should be well distributed, and each floor's lights controlled in several groups for the sake of economy of current. Around the walls, at frequent intervals, receptacles should be installed for drop cords so that these need not be of an unhandy length. The wall receptacles should be of sufficient capacity to take care of a portable drill.

The heating system should be ample to keep all floors, where cars are stored, up to at least 30 degrees during the coldest weather. This is essential in order to start the batteries out warm. A gasoline garage can get along with any temperature above 32 degrees, but not so with the electric.

The charging equipment, switchboard, wiring, etc., should be of approved type, solid and well erected. This apparatus is so standardized that no special remarks are necessary except to suggest that rheostats, being usually grouped as closely together as their frames will permit, should be ventilated in summer.

Ventilation should also be well looked to in the battery repair room, for here batteries are often gassing for a day or more on their initial charge. The floor of this room demands special attention, acid-proof brick or tiles laid in pitch being the best construction. It is of the utmost importance that the drainage system from this department—all the way to the sewer—should be either of lead or glazed earthenware, and preferably run as "open plumbing," not buried in the walls.

A small machine tool equipment is a very useful adjunct in an electric garage, even where most of the work is sent out. A lathe, drill press and emery wheel will do most of the odd jobs that come up from day to day. A more complete equipment would include a sharper milling machine and power hack-saw. If the garage is to be complete to handle everything that may become necessary, it should include well-equipped carpenter and paint shops. There is much to be said in favor of this, since then a car need never leave the garage except for its daily work.

Now as to management: In the first place, let there be one head to the entire system. If it is possible (and it ought to be nowadays) to combine in one person business ability and a thorough technical knowledge of the industry, then this is the desideratum. If not, then let the head be by choice a good business man, with a broad enough mind to know his limitations in other fields and to trust his well-chosen subordinates.

There are a number of important questions that come up for decision almost daily in the operation of a garage. For instance, shall the customer be billed for accidents which may have been preventable? There are some garage managers, I am afraid, who regard such accidents in the light of "acts of Providence" especially provided to furnish them a source of revenue. In general, it may be said that a public garage cannot afford to have as many really preventable accidents as a private garage can.

Another question is, just what repair shall be included in the flat monthly rate? Minor adjustments are conceded without extra charge, but there are a number of repairs that become necessary from time to time that hardly come under this head. An owner asks to have his smashed tail lights straightened out, or new licenses put on, or perhaps says: "Just lend me a bell, or a spring, or an armature (as the case may be) until mine is repaired," the word "just" indicating that he does not expect to be charged for the service. Sometimes it is hard to decide just how far generosity can be stretched, but, as a rule, I may say that it all depends on the customer's record.

Small Cars Pay the Dividends

At the present rates charged for garaging, the small cars are the ones that pay the dividends. This is not because the rates are so far from equable, but because the small car on the average does not carry so large a proportion of its possible load as does the large one.

In dealing with the owners of commercial cars, as a rule, it is only the recent purchaser who is unreasonable and not willing to meet the garage management half way in the matter of disputes on bills or service rendered.

A few words about pleasure cars:

In dealing with the owners of pleasure cars, considerable tact is required, rather than straight business acumen. A good many of these owners have no special interest in understanding the workings or limitations of their cars, and consequently there is no common ground on which an argument can be based. On the other hand, some owners consume a lot of the garage manager's time in arguments and explanations of "how it all happened." Both the commercial car manager and the pleasure car manager have all they can do, but the first has the easier job.

The 1913 Targa Florio

Nazzaro's Skilled Driving and Reliable Car Are Winning Factors

PALERMO, SICILY, May 14—Felix Nazzaro's success in the Targa Florio race was due to skilled driving and an absolutely reliable car. It was a race in which the man counted for much. Starting from Palermo, the competitors had to make a complete circle of the island of Sicily, the road keeping within sight of the Mediterranean practically the whole of the way. Throughout the 650 miles there was not a straight stretch of more than a quarter of a mile, the greater portion of the route forming a ledge cut on the mountain side, with hairpin turns, and short, steep gradients. The regulations allowed a cylinder volume of 549 cubic inches, but owing to the nature of the road it was impossible to make use of all the power available from such dimensions and very few of the competing cars approached the limit. Quick acceleration was an important factor, the weight problem had to be carefully studied, the cars required a wide steering lock and moderate wheelbase and the course was too dangerous for dare-devil driving. No attempt was made to guard the roads: the competitors had to take their chance of meeting with mountain mules which became scared at the sight of an automobile, and of Sicilian peasants who were hardly less frightened.

Thirty-seven Cars Start

Thirty-seven cars lined up for the start, which was given in the center of the town of Palermo at 5 a. m., the first car to get away being a Minerva with Knight motor. The others followed at intervals of 10 minutes. Practically all the cars were standard touring models stripped as low as possible for racing purposes. The equipment consisted of nothing more than a couple of seats, a gasoline tank, three to five spare wheels or tires, and a couple of headlights. These latter were necessary on account of the start of the second stage of the race being given to the leading car at midnight. Italians figured most prominently in the race. Among the foreigners were five American cars: an Overland, two Fords, a Metz, and a Flanders. France had an eight-cylinder De Dion Bouton and a 20-30 Renault; Belgium had one Minerva, with Knight motor; Switzerland had a couple of Sigma, also with Knight motor: and Germany was represented by a Mercedes team.

The first stage stopped at Girgenti, after a run of 447 miles. The real struggle on this stage was between Felix Nazarro, on his own car and Marsaglia on the Aquila-Italiana of which he is the designer. Marsaglia had started eighth, or nearly 2 hours before Nazzaro, and was therefore not aware how dangerous his competitor might be. This first stage proved a weed-

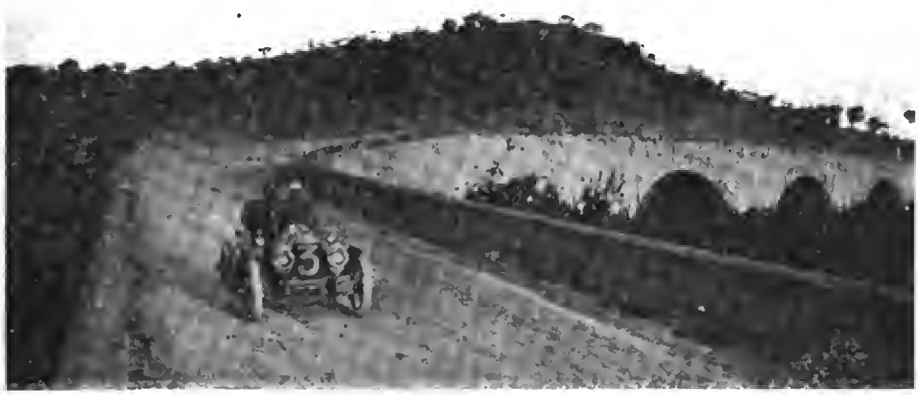
Fracassi taking the curves in a Ford

Giordano coming through a pass in his Fiat

Nazzaro, the winner, and his Nazzaro car

Berra, fourth, in his eight-cylinder De Dion

in Picture and in Story



Demoraes crossing a culvert in his Fiat

Cerano and his S.C.A.T. at high speed

Diana, Isotta, was ninth to finish the race

Berla and his Aquila ready for the race

ing out of the weaker cars and of the less skilled of the drivers, only sixteen of the competitors getting to Girgenti within the time allowance. Marsaglia maintained his lead on the first day's run with an advantage of 30 minutes on Nazzaro. Bordino on Lancia came in a very close third, there being an interval of more than an hour between this car and the fourth. Of the American competitors only the Overland was able to finish the first stage, Lopez bringing his car into tenth position sandwiched between a De Vecchi and an Isotta.

On their arrival at Girgenti the cars were locked up, the continuation of the race being fixed for midnight for the first car, Marsaglia's Aquila-Italiana, the others following with the same interval as marked their arrival. At an early stage Marsaglia had trouble with his headlights, which gave Nazzaro a chance to creep up to him and finally get ahead.

Bordino, who had finished the first stage a good third, had trouble on the second day's run, causing him to fall back to eighth place.

One of the rotary valve Italas dropped out, and the Overland crept up two places, finishing seventh. The cars which fell out on the second day's run were Itala, Isotta, Fiat, Sigma (Knight), and Mercedes.

Speed Was 33.5

Nazzaro's speed worked out at the average of 33.5 miles an hour, which is considerably faster than any other competitor has made over this course. In 1907 Nazzaro won the Targa Florio for Fiat, the race on that occasion being three rounds of the island. The winning Nazzaro car is a standard model built by Nazzaro at Turin, and having a four-cylinder block motor of 3.9 by 5.5 inches bore and stroke. The cylinder make, a fine, clean-cut casting with integral intake and exhaust manifolds, and having the body of the water pump cast with the crankchamber.

The Aquila-Italiana with which its designer, Marsaglia, finished second, has a six-cylinder motor of 3.1 by 5.1 inches bore and stroke, the construction being distinctive by reason of the block casting of cylinders and upper half of crankchamber.

Results of Targa Florio Race

Nazzaro	Nazzaro	19:28:40
Marsaglia	Aquila-Italiana	20:43:49
Gloria	De Vecchi	21:48:04
Berra	De Dion Bouton	22:22:25
Giordano	Fiat	22:26:04
Sivocci	De Vecchi	22:47:00
Lopez	Overland	23:12:47
Pordino	Lancia	23:43:25
Diana	Isotta	23:46:00
Stabile	Minerva (Knight)	23:59:04
Turner	Renault	24:30:00

Position at End of First Stage

Marsaglia	Aquila-Italiana	13:04:13
Nazzaro	Nazzaro	13:34:44
Bordino	Lancia	13:56:52
Giordano	Fiat	15:03:34
Gloria	De Vecchi	15:14:09
Stabile	Minerva	15:16:37
Berra	De Dion Bonton	15:22:19
Negri	Itala	15:31:51
Sivocci	De Vecchi	15:38:10
Lopez	Overland	15:52:39
Diana	Isotta	16:15:57
Turner	Renanlt	16:17:21
Conti	Isotta	17:38:08
De Romase	Fiat	17:42:12
De Prosperi	Sigma (Knight)	18:27:00
Inglese	Mercedes	19:09:23

Developments in the Trade Field

SPLITDORF Service Station Established—The Splitdorf Electric Co., Newark, N. J., has established a thoroughly equipped service station. J. H. Dickinson is manager.

Newton Opens Cedarhurst Garage—S. E. Newton has opened a garage in Cedarhurst, L. I.

Philadelphia Hood Tire Agent—The Petry-Cassidy Co., Philadelphia, Pa., has been appointed agent for the Hood tire.

Haskins Krit Manager—C. B. Haskins has been appointed manager of the retail branch in Buffalo, N. Y., of the Krit Motor Car Co.

Lininger Keeton Purchasing Agent—W. Lininger has joined the Keeton Motor Co., Detroit, Mich., as purchasing agent and office manager.

Chicago Ward Leonard Agent—The Badt-Westburg Electric Co., Chicago, Ill., has been appointed agent for the Ward Leonard Electric Co., Bronxville, N. Y.

Peete Rayfield's Detroit Manager—R. C. Peete has been appointed manager of the Detroit, Mich., branch of the Rayfield carbureter, located at 997 Wodward avenue.

Edwards Adopts Hartford Absorbers—The Edwards Motor Car Co., Long Island City, N. Y., has adopted Truffault-Hartford shock absorbers as standard equipment.

Ajax In New Location—The Boston, Mass., branch of the Ajax-Grieb Rubber Co. has been moved from Park Square where it was for years to a new home at 1084 Boylston street.

Powers Hood Tire Manager—F. Wade Powers has been appointed general manager of Petry-Cassidy, Inc., Philadelphia, Pa., which recently took the local distribution of Hood tires.

Jameson Resigns from Maxwell—W. B. Jameson, who was with the Maxwell-Briscoe Motor Co. from 1904 on, has resigned his connection with the Maxwell Motor Co., Inc., Detroit, Mich.

Weber Out of Walpole—E. P. Weber, who has been manager of the Boston, Mass., branch of the Walpole Tire Co., ever since that company made its entry into the tire business, has resigned.

Adams Stewart-Warner Advertising Manager—Gridley Adams has been appointed advertising manager of the Stewart-Warner Speedometer Corporation, with headquarters at the Chicago, Ill., plant.

Cowling Resigns from Case—J. G. Cowling, for the past 12 years connected with the J. I. Case T. M. Co., Racine, Wis., has resigned to accept a position as vice-president of the Federal Pressed Steel Co., Milwaukee, Wis.

Oldsmobile Change—W. B. Fewell, for some years manager of the New England branch of the Oldsmobile at Boston, Mass., has just resigned and his place has been filled by the appointment of L. G. Dodge.

Overland's Racing Track—The Willys-Overland Automobile Co., Toledo, O., has purchased sufficient land in the rear of its Central avenue plant to build a half-mile racing track. This track will be used for testing cars.

New Marion Garage—N. H. Davis, Marion, O., agent for the Ford, has purchased a site on South Prospect street upon which he will erect a one-story garage and salesroom. The structure will be of cement block construction.

With Campbell-Ewald Co.—N. T. Brotherton, formerly secretary and advertising manager of the Keeton Motor Co., Detroit, Mich., has resigned those connections to join the staff of the Campbell-Ewald Co., advertising specialists, that city.

Malley Resigns In Boston—Charles Addison Malley, who was instrumental in forming the M-B-M Co., to handle the Maxwell line at retail in Boston, Mass., has resigned and the new company is now under the management of E. H. Marsters.

Humpage in New Field—F. R. Humpage is now president of the International Color & Chemical Co., Inc., Buffalo, N. Y. This company is now installing a plant in Bridgeport, Conn., which will be in active operation within the next 2 weeks.

Bradford Joins Maxwell—J. R. Bradford, for the past 5 years assistant manager of the Boston, Mass., branch of the Buick Co., who recently resigned, has been made sales manager of the M-B-M Co. of that city, retail handler of the Maxwell cars.

Wolverine Club Quarters Moved—The quarters of the Wolverine Automobile Club, Detroit, Mich., have been removed from the Tuller Hotel to the new location in the Springfield Building, on Woodward avenue opposite the Pontchartrain Hotel.

Mayo On the Job—George H. Mayo, formerly with the Hubmark Rubber Co., is now the manager of the Enterprise Rubber Co., in Boston, taking the place formerly occupied by William E. Barker, who has gone to New York with the U. S. Rubber Company.

Wacker Resigns from Simms—G. W. Wacker has severed his connection from the Simms Magneto Co., New York City. He was sales manager of this company prior to its reorganization last July. Since then he was the engineer in charge of the Bloomfield, N. J., works.

Detroit Firm Surrenders Charter—The Lee & Porter Mfg. Co., Buchanan, Mich., recently consolidated with the Lewis Spring & Axle Co., Jackson, Mich., and will surrender its charter and all its business in the future will be carried on under the direction of the Lewis concern.

Oakland Moves In Boston—Manager Fred Walsh of the New England branch of the Oakland Motor Car Co. has moved the Boston, Mass., salesrooms from Boylston street to the old quarters of the United Motors Boston Company, corner of Massachusetts avenue and Newbury street.

Will Motorize Mail Service—Two automobiles used in the collection of mail in New Orleans, La., have proven that they can handle the work of eight of the wagons which are in use. The test was made under the personal observation of the superintendent of mails, who has authorized the installation of two cars for the service. It is intended to motorize the entire service.

Automobile Mart Formed—The Automobile Mart Assn. was recently formed in St. Louis, Mo., by J. J. Behen, who is its president. Its purpose is to facilitate the sale of used, renewed and rebuilt automobiles. Arrangements are being made for the holding of a mart in the near future where a large assortment of automobiles and trucks of different makes and models will be displayed and demonstrated.

Gasoline Freight Rates Cut—The United Fruit Co. has made a 20 per cent. cut in its freight rate on gasoline between New Orleans, La., and Puerto Barrios. This is the result of a protest made by the automobile owners in Guatemala City. The government also has been asked to reduce the duty on gasoline so that the price, which is almost prohibitive, from 75 cents to 85 cents a gallon, may be reduced.

New Lozier Manager—The resignations of manager R. B. Nettleton and George C. Crittenden, as branch manager and sales manager respectively of the New England branch of the Lozier, recently brought sales manager Paul Smith to Boston, Mass., on a hurried trip to install E. R. Hunnewell as manager of the New England branch. Messrs. Nettleton and Crittenden have gone over to the newly formed Chandler Motor Car Co. of New England, and will occupy the same positions they had with the Lozier branch. Temporary salesrooms have been secured at the new Fenway garage in the Back Bay.

Cultivating Rubber In Peru—In order to make possible the cultivation of rubber in the Madre de Dios region of Peru the government has established an agricultural experiment station. The reckless exploitation of the wild rubber trees in recent years is resulting in the death of many trees and ultimately will mean the stopping of the supply unless steps are taken quickly to protect the trees and arrange for cultivation. The government is offering inducements to colonists to undertake the cultivation of rubber plants. Instruction to the farmers of the Madre de Dios region will be given free at the new station.

Many Factories Under Construction

GORDON Rubber Erecting Plant—A contract will be let in the near future by the Gordon Rubber Co., Canton, O., for two brick buildings to be erected at Williams street and the B. & O. crossing. The company expects to occupy the new structure by July 15. The main plant of the company is now located at Beach City, O., and it will be consolidated with the Canton, which will be the headquarters. The new plant will cost $25,000, consisting of two buildings, one story high, one to be 165 by 40 feet and the other 200 by 40 feet.

Bridgeport Motor Co.—The Bridgeport Motor Co., Bridgeport, Conn., is erecting an addition to its plant.

Allen Contemplating Addition—The Allen Motor Car Co., Fostoria, O., is considering the erection of an addition to its factory.

A. & J. Doubles Capacity—The A. & J. Mfg. Co., Binghamton, N. Y., has completed plans for the doubling of the capacity of its plant on Noyes Island.

New Equipment Worth $30,000—The Chicago, Ill., Pneumatic Tool Co., manufacturer of the Little Giant motor truck, is adding $30,000 worth of equipment to its factory.

U. S. Rubber Adding—The United States Rubber Co., Indianapolis, Ind., is building a new addition to its Indianapolis, Ind., plant and is using reinforced concrete for frame, floors and roof.

Hughey Will Erect—W. J. Hughey & Son Co., Chicago, Ill., will erect a factory on Prairie avenue and Thirty-third street for the manufacture of motor trucks. The estimated cost is $100,000.

Chase Doubles Office Capacity—The Chase Motor Truck Co., Syracuse, N. Y., has had plans completed for doubling the capacity of the general offices and extending the manufacturing facilities.

Rochester-Mais Plans Factory—The Rochester-Mais Commercial Car Co., Rochester, Ind., recently organized, is having plans prepared for a new factory to be used for the manufacture of motor trucks.

Ford's Chicago Warehouse—The Ford Motor Co., Detroit, Mich., is proceeding with the construction of its six-story factory and warehouse at Chicago, Ill. The building will be 160 by 230 feet and will cost $400,000.

Hewitt's Three-Story Building—The Hewitt Rubber Co., Buffalo, N. Y., has been granted a permit to proceed with the construction of a three-story factory building, to be of concrete and cement construction and 40 by 48 feet in size.

One Hundred Hups a Day—The Hupp Motor Car Co., Detroit, Mich., is building and shipping 100 Hupmobiles a day. This company has erected a huge tent adjoining the executive building to be used for assembling purposes and a test department.

Trenton Company Builds Addition—The Fitzgibbon & Vrisp Co., Trenton, N. J., manufacturer of carriage and automobile bodies, has taken out a permit to build an addition to its plant. The structure will later be equipped with new machinery.

Overland Planning Extension—The Willys-Overland Co., Toledo, O., is planning for a further extension of its Toledo plant and to make it possible for it to do so the City Council at its last meeting vacated a number of streets and alleys, most of which were paper thoroughfares only.

Bids $22,500 for Middleby Plant—Although $22,500 was offered for the plant of the Middleby Automobile Co., Reading, Pa., at public sale recently held by the executor, M. A. Gherst, the sale was continued, because, in his opinion, the bid was too small. For the building $13,000 and for the equipment $9,500 was bid.

Pope's Production Increasing—The production at the factory of the Pope Mfg. Co., Hartford, Conn., has been at a good rate and without interruptions. To date the company has built approximately 1,100 Pope-Hartfords as against 531 in the same period in 1912 season and 820 for all the twelve months to July 31 last.

Jefferson Wants New Firm—At a meeting of the business men of Jefferson, O., recently, a resolution was adopted providing that as soon as the Pressed Steel Motor Car Co. would bring a completed car to Jefferson and place $25,000 in a local bank, the citizens of that city would raise $25,000 to buy a site and erect the initial building for the establishment of the automobile concern.

Ohio Electric Planning Extension—The Ohio Electric Automobile Co., Toledo, O., is planning an addition to its plant which will practically double its capacity and will employ 200 additional men. The Ohio Electric makes 55 electric pleasure vehicles a month. The new building will adjoin the present four-story brick plant, will be of the same height and dimensions, and will cost $100,000.

Swartz Electric Purchases Factory—The Swartz Electric Co. has bought a factory building and 1 acre of ground opposite the Indianapolis, Ind., Motor Speedway, the consideration being $10,000. Arrangements are to be completed immediately to erect two additional fireproof factory buildings and these and the building now on the site will be occupied by the company, which manufactures electric lighting equipment.

The Automobile Calendar

Shows, Conventions, Etc.

June 2-7	Racine, Wis., "Made in Racine Exposition," J. I. Case Co.'s foundry.
June 5, 6, 7	Detroit, Mich., Midsummer Meeting of Society of Automobile Engineers.
October 13	Philadelphia, Pa., National Fire Prevention Conference, Philadelphia Fire Prevention Commission.

Race Meets, Runs, Hill Climbs, Etc.

May 29-30	Chicago, Ill., Inter-Club Reliability to Indianapolis, Ind., Chicago Motor Club vs. Illinois Athletic Club.
May 30	Indianapolis, Ind., 500-Mile Race, Speedway.
June 5	New York City, Orphans' Day Picnic at Glen Island, Orphans' Automobile Day Assn.
June 7	Philadelphia, Pa., Inter-Club Reliability, Quaker City Motor Club, Automobile Clubs of Delaware County, Philadelphia and Germantown.
June 10	Columbus, O., Reliability Run, Columbus Automobile Club.
June 14	Cincinnati, O., Hill Climb, Cincinnati Auto Dealers.
June 14-15	San Francisco, Cal., Track Races, E. A. Moross.
June 16, 17, 18	Columbus, O., Reliability Contest, *Ohio State Journal*.
June 19	Chicago, Ill., Algonquin Hill Climb, Chicago Motor Club.
June 21	Cincinnati, O., Hill Climb, Cincinnati, O., Automobile Dealers.
June 21	Philadelphia, Pa., Fletcher Cup Run, Automobile Club of Philadelphia.
June 21-22	San Francisco, Cal., Track Races, E. A. Moross.
June 23	Des Moines, Ia., Little Glidden Tour, Iowa Automobile Assn.
June 25-28	Chicago, Ill., Non-Motor-Stop Reliability, Chicago to Boston, Chicago Automobile Club.
July 1	Indianapolis, Ind., Tour of Indiana Automobile Manufacturers' Assn. to the Pacific Coast.
July 1-16	Winnipeg, Man., Motor Plow Competition, Dr. A. W. Bell, Manager.
July 4	Columbus, O., 200-Mile Track Race, Columbus, O., Automobile Club.
July 4	Taylor, Tex., Track Meeting, Taylor Auto Club.
July 4	Washington, D. C., Track Races, National Capital Motorcycle Club.
July 4-5	Sioux City, S. Dak., Track Meetings, Sioux City Automobile Club and Speedway Assn.
July 5-6	Tacoma, Wash., Road Race, Montemara Festa Automobile Committee.
July 8-16	Winnipeg, Man., Midsummer Exhibition, A. C. Emmett, Manager.
July 11	Twin City, Minn., National Reliability Tour, A. A. A.
July 20	Seattle, Wash., Track Races, E. A. Moross.
July 27	Grand Rapids, Mich., Tour, Grand Rapids Auto Club.
July 27-28	Tacoma, Wash., Tacoma Road Races.
July 28-29-30	Galveston, Tex., Beach Races, Galveston Automobile Club.
Aug. 5	Kansas City, Mo., Sociability and Endurance Run from Kansas City to Colorado Springs, Col., Kansas State Automobile Assn.
Aug. 12	Kansas City, Mo., Reliability Tour, Kansas State Auto Assn.
Aug. 29-30	Elgin, Ill., Elgin Road Races, Elgin Road Race Assn.
Aug. 30-Sept. 6	Chicago, Ill., Reliability Run, Chicago Motor Club.
Sept. 1	Columbus, O., 200-Mile Track Race, Columbus Auto Club.
Sept. 9	Corona, Cal., Track Race, Corona Auto Assn.
Oct. 4-11	Chicago, Ill., Around Lake Michigan Run, Chicago Motor Co.
Nov. 24	Savannah, Ga., Vanderbilt Cup Race, Motor Cups Holding Company.
Nov. 27	Savannah, Ga., Grand Prize Race, Automobile Club of America.

O'Kill Is a Simple Pressure Indicator

By Professor W. C. Marshall

IT is a well-known fact that the successful design and the economical working of the steam engine were brought about by the invention of the indicator.

The original design consisted of a tube within which a spring was compressed by the pressure of the steam from the engine cylinder acting on a piston fastened to one end of the spring. The movement of the piston was recorded on a strip of paper by means of a pencil attached to the moving piston. The paper was made to move by connecting it to the reciprocating parts of the engine.

The first engines to use such indicators made few revolutions per minute and used steam at low pressure.

The line traced by the pencil on the moving paper was an indication of the pressure within the cylinder of the engine at every point of the stroke of the piston.

As the speeds of engines increased the inertia of the spring caused the pressure line of the indicator card to become a series of waves, making it difficult to determine the true pressure line.

Shortening the spring and at the same time lightening the moving parts of the pencil-actuating mechanism, obviated this difficulty for speeds used in steam engine practice.

When gasoline engines began to increase in numbers the same difficulty, which had caused steam engine designers so much difficulty years before, presented itself.

The optical indicator or manograph was invented to be used at speeds of rotation of from 700 to 2,500 revolutions per minute. The pencil of the old style indicator was replaced by a beam of light. This beam of light striking a ground glass screen traced on it the indicator card of pressures in the engine.

Permanent records were made on sensitized paper which was afterwards developed and fixed in the photographic dark room.

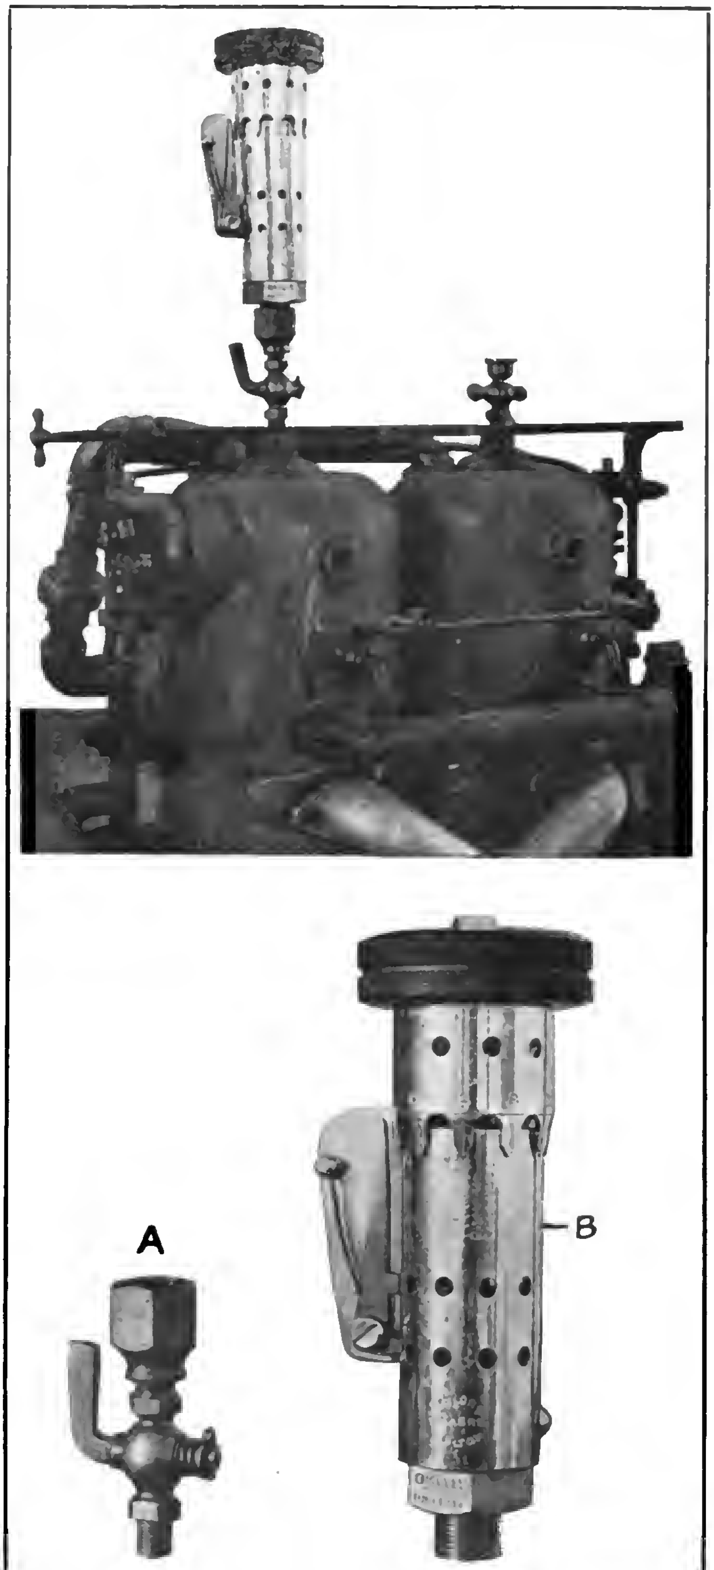


Fig. 1—Upper: O'Kill Indicator as it appears mounted on the cylinder ready to give pressure readings. Lower: Enlarged view of the O'Kill indicator and the valve by means of which it is attached to the motor cylinder which is to be tested by the instrument

The manograph was expensive, hard to attach, and much too cumbersome to carry on an automobile or motor boat.

As the power of an internal combustion engine depends on the compression and explosion pressures in its cylinders, it becomes an important matter to determine what these factors are in a given engine.

In case there are several cylinders it is advisable to divide the work equally among them. This can only be done by having the same compression and explosion pressures in them all.

A manograph is not necessary to determine these pressures, nor could it be used without considerable trouble.

Mr. J. O'Kill, M.I.A.E., has designed a pressure indicator which enables the maximum pressure in an internal combustion engine cylinder to be determined accurately and easily.

This instrument is shown in Fig. 1, and is about 7 inches high, its maximum diameter being 2.5 inches. It is attached to the motor by screwing into the spark-plug hole, in case there are two plugs in the cylinder, or by unscrewing the petcock used for priming and screwing in the connection shown in Fig. 1 at the lower left.

This serves for one cylinder at a time in a multi-cylinder motor. Other arrangements for rapidly connecting each cylinder to the indicator will be shown further on.

The working of the indicator is explained by referring to Fig. 2, which is a vertical longitudinal section.

Pressure from the cylinder of the motor enters the casing A through the hole H_1 and causes the piston B to rise a short distance. This upward motion is opposed by the plunger F which is pressed downward by the helical spring.

Any rise of B causes the bell crank H to turn about its fulcrum K and its upper end to vibrate along the scale E.

By turning the milled rubber head L of the sleeve D the compression of the spring may be varied until the piston B does not rise and the finger H stops vibrating.

The lower edge of sleeve D is made like a micrometer caliper.

On the casing C is a vertical scale graduated to 40 pounds. One complete turn of the sleeve D causes a vertical motion equal to one of these divsions and adds or takes off 40 pounds from the spring. As the lower edge of the sleeve is divided into ten divisions by turning it through the space of one division we can read to 4 pounds.

These divisions, as well as the graduated vertical scale, are shown at B in Fig. 1.

Plunger F can rise but a short distance before striking the casing C.

Its lower end is spherical and bears against the top of piston B.

A hole is drilled from the outside of the piston B to its axis, where it meets a hole drilled from the top of the piston.

As the plunger and its stem also have an axial hole, any oil injected at the top of the plunger stem finds its way to the outside surface of the piston, preventing leakage and sticking of the piston.

If we wish to obtain the compression pressure in a cylinder the indicator is attached as explained previously and the milled head rotated until the graduated scale reads 40 pounds. The cock between indicator and cylinder is opened after cutting off the ignition spark from the cylinder.

If the finger H vibrates the sleeve is screwed down until this vibration ceases. The sleeve is then gradually screwed back until the finger commences to show a slight movement.

By placing one's finger lightly on top of the oil tube any movement of the plunger can be easily detected.

The divisions on the casing and sleeve are then read to obtain the pressure in the motor cylinder.

The explosion pressure is obtained by connecting the spark plug and igniting the charge of gas in the cylinder.

As the pressure is liable to be 300 pounds or more it is advisable to screw the sleeve down to this pressure and then to turn it back, in case the finger does not vibrate.

In order to obtain the true compression pressure under load conditions it will be necessary, in the case of an automobile motor, to run with throttle wide open either on the road or by cutting off enough cylinders to prevent racing of the motor and centering the load on the remainder.

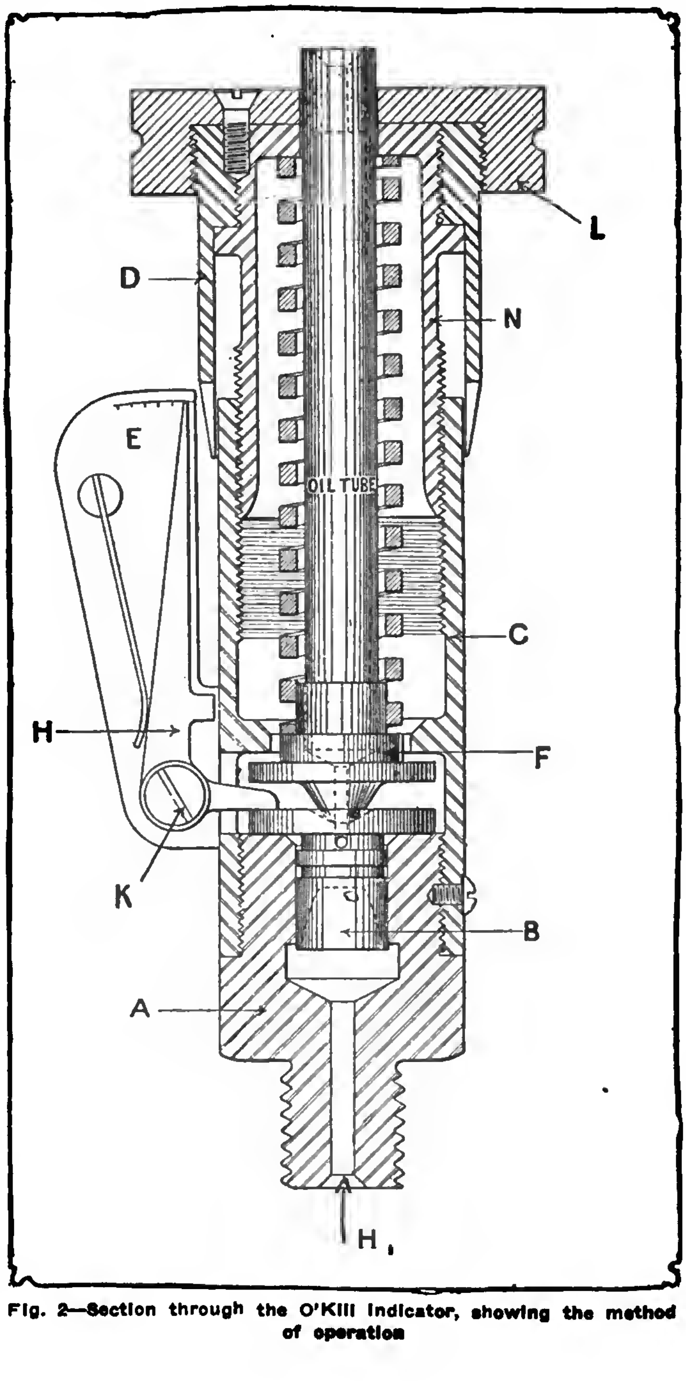

Fig. 2—Section through the O'Kill Indicator, showing the method of operation

The ignition should be in full-advanced position when obtaining the explosion pressure.

When several cylinders are tested it is advisable to carefully mark the throttle position, in order to obtain the same conditions for each cylinder.

When the indicator is used on an automobile motor it will appear as shown in Fig 1. In this case the petcock has been removed and the connection of A, Fig. 1, used.

The writer has found it difficult to use this connection on some cars and so designed the attachment shown in Fig. 4. This can be attached to a priming cock without removing the cock.

Piece A is slipped over the cock shown in X. B is then screwed into the top of A so that the bottom end of it presses tightly over the hole in the cock. The indicator is then screwed into B, making the complete connection from cylinder.

If it is not possible to screw the indicator into B, the fitting C is used instead, and a copper pipe connection made to the indicator which may be clamped to some fixed part of the automobile in a convenient place. Y shows how A, B and X appear when assembled.

The best way of indicating a multicylinder motor is to screw the indicator into a manifold from which a pipe runs to each one of the cylinders. By means of a cock at each cylinder it may be instantly connected to the manifold and the pressure can be read on the indicator.

By arranging a cut-out it is easy to cut the ignition off in any cylinder and take the compression reading.

Occasionally the manifold is provided with cocks and located on the dash of a car, which enables readings to be made while running on the road. A falling-off in power of the motor means poor compression and this is instantly shown by the indicator pressure.

The loss of compression may be due to leakage past the piston or the valve seats.

Too rich or too weak a mixture will give a low explosion pressure. Faulty ignition or ignition too much retarded is indicated by a low explosion pressure.

In a car running with wide-open throttle on a slight ascent the writer found the compression pressure to be 50 pounds per square inch and explosion pressure 212 pounds per square inch.

In this case the indicator was placed on one cylinder only and readings had to be taken by an observer seated on the mud guard over the front wheel.

The motor was 48 horsepower, six-cylinders, 4½ by 5½ inches.

Another six-cylinder car of

30 horsepower, tested with wide-open throttle on a slight ascent had a maximum compression of 64 pounds, with maximum explosion pressure of 260 pounds.

The indicator was attached to the dash and piped to one cylinder. Readings could easily be made from the front seat and those given above were the highest observed.

The ignition of the cylinder tested was arranged to be easily cut off by a short-circuiting device operated from the front seat of the car.

These two experiments show the value of higher compression in obtaining increased explosion pressure.

Determination of both of these pressures can be made very easily with this indicator.

The writer has made a number of tests to determine the compression and explosion pressures in automobile motors running idle with the car standing still. The throttle, of course, is nearly closed, which accounts for the low pressures obtained.

The following table shows the results of these tests.

Car No.	H.P.	No. Cyls.	Spark	Compression lbs.	Explosion lbs.
1	36	6	Normal	7	6
2	48	6	"	9	8
3	..	4	"	15	12½
4	..	4	"	12	9
5	48	6	"	7	10
5	48	6	Retard	8	8½
5	48	6	Adv.	6½	8½
6	72	6	Normal	6	15
4	60	4	"	11	15

It can be seen by inspection that the pressure in the cylinder at the commencement of the compression stroke must be considerably below atmospheric pressure due to the inability to suck in the charge against the resistance of the closed throttle. The low explosion pressure is probably due to delayed ignition or to a mixture of burned gases with the fresh charge, on account of the exhaust back pressure in the manifold.

The average pressure is very small as the work is done simply in rotating the crankshaft, moving the pistons, connecting-rods, valves, pump and magneto.

An approximate indicator card can easily be drawn by using the above pressures, provided the points where the inlet and exhaust valves open and close are accurately known.

The indicator readings taken with wide-open throttle will give in a similar manner the approximate card for full power, and thus enable the indicated horsepower to be obtained if the revolutions per minute of motor are known. As an example of this take the car numbered 5 in the table. This was the car the compression and explosion of which were noted previously as 50 and 212 pounds respectively.

The motor was 4½ by 5½, six cylinders, and was turning at approximately 600 revolutions per minute when the readings were taken.

The inlet valves opened about 8.5 degrees after the top dead center and closed 47.5 degrees after bottom dead center.

The exhaust valves opened 44 degrees before bottom dead center and closed 4.5 degrees past top dead center.

The clearance volume was assumed to be one-third the volume displaced by the piston movement; therefore C1 in Fig 3 was made one-third of the stroke.

The expansion and compression curves were assumed to follow the same law, namely, (PV) 1.33 = constant.

They were constructed as shown, laying off α and β by their tangents, as given.

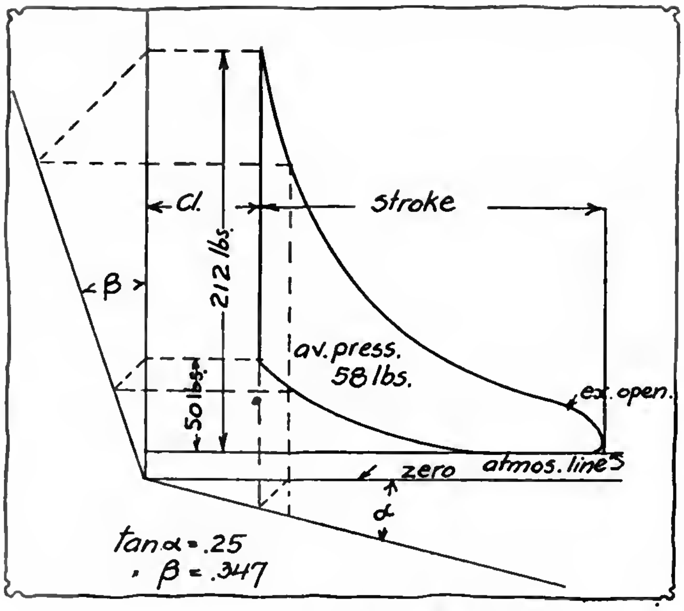

Fig. 3—Indicator diagram for determining engine performance

From this indicator card the average pressure was found to be 58 pounds.

As there are six cylinders the power of one cylinder must be multiplied by six.

The area of piston was 15.9 square inches. The stroke was .458 feet.

From this data the indicated horsepower is calculated to be 23.

This is calculated for a car speed of approximately 20 miles per hour, with a 3.3 gear ratio on direct drive.

By the simple reading of the explosion and compression pressures we are thus enabled to calculate the horsepower of a motor running on the road on a slight grade.

If the grade were measured and the coasting resistance of the car as well, the efficiency of the whole mechanism could be calculated for this speed. Other speeds give different results, as regards the power, because of the increase or decrease in revolutions per minute of the motor.

At high speeds the volumetric efficiency reduces the compression pressure, with consequent falling off of average pressure in the cylinders. This can be observed with the pressure indicator and the torque curve of the motor plotted from these observations.

Laboratory experiments with the indicator on multi-cylinder motors show whether or not the cylinders are giving equal power and enable the one at fault to be instantly located. The indicator can also be used as a check on the other indicators used for making cards.

Fittings are shown in Fig. 4. which can be used to advantage as permanent fixtures.

A is used where the cylinder has no opening to connect the indicator except the spark-plug hole.

The plug is then removed and the end a screwed into the hole.

The plug is screwed into b and the indicator into c.

B is a bracket connected to two cylinders by the small pipes.

The cocks provide a quick connection to these pipes from the indicator, which screws into a.

C is a four-cylinder arrangement provided with manifold, cocks, and cylinder pipes.

The indicator is at a and can be connected to any one of the cylinders by opening the proper cock.

D is an arrangement for a launch having a two-cylinder motor.

The pipe from the indicator passes through the bulkhead to a two-way cock where it branches to each cylinder.

A good method of attaching the indicator to a permanent fixture on a cylinder is to use a bayonet joint, as shown in Fig. 4, at the right side of the illustration.

Part A screws on the indicator and fits into part B.

The pin X slips down in groove y and as A is turned it moves the pin along the slot, which is sloping down, thus forcing the end of A against the bottom of the conical hole in B.

It can be instantly detached by rotating A in the opposite direction.

The price of the indicator is $17.50 in England, where it is made and extensively used.

In this country it would probably be about $27, which is not prohibitive.

Manufacturers and users of internal combustion motors can certainly profit by having such an aid in the running and testing of their motors, easy to attach and easy to read as well as being accurate.

Among the New Books

Technical and Non-Technical Works for Both the Layman and the Engineer Recently Announced

THIS is a busy season for the publishers of engineering and kindred works, and it may be said that the reading of such literature is rapidly on the increase and is keeping pace with the development of scientific subjects in the universities. The following list will show some of the latest.

COMPLETE HINTS AND TIPS FOR AUTOMOBILISTS, fifth edition, from *The Autocar*, London, and published by Iliffe & Sons, Ltd., London, England; classified in 500 paragraphs; illustrated; Boards, 2 shillings, 6 pence. (60 cents.)

Given in a series of paragraphs, these tips should come in handy for the man who drives his own car. A comprehensive index renders it possible to find the necessary information with the least possible effort. The index is crossed so that the reader may find the needed paragraph without making two or three guesses at the most important word. These pieces of information are selected from *The Autocar*, only such being picked out as the composers have judged to be of practical value to an amateur only. The methods of making various repairs, of storing a car, driving in risky places, the constituents of various compounds used in automobiling, etc., are all to be found within its pages.

A 5 YEARS' FIGHT AGAINST FIRE WASTE, AND ITS POSSIBLE CONTROL IN THE UNITED STATES BY FIRE PREVENTIONS AND PROTECTION. By Powell Evans. Published by the Merchant & Evans Co., Philadelphia, Pa.; 180, 6 by 9 inch pages. Paper, 25 cents.

The annual waste by fire in the United States amounts to hundreds of millions of dollars. In Philadelphia alone it amounts to $2,500,000 a year, and this is good as compared on a per capita basis with other cities. The annual per capita loss in Philadelphia is $1.65. In the entire United States the average per capita fire loss is $3, or, in other words, $270,000,000 a year is lost in fires in the United States. Boston has the highest per capita loss, amounting to $5.15. As compared with some of the foreign cities, this is tremendous. In Berlin the annual per capita loss is 25 cents. in Paris it is 47 cents, in London, 50 cents. This is a subject which is well worth the study of those interested in economics. Fire protection is not always an expense. In one case where sprinklers were put into a building the price of the installation was saved on the reduction in premium in 2 years. This was on a $1,000,000 policy. The papers contained in this pamphlet are full of interesting facts many of which are brought home in a startling manner.

FAULTS AND HOW TO FIND THEM. By J. S. V. Bickford, B. A., a list of 180 faults, their symptoms and remedies; published by Iliffe & Sons, Ltd., London, England; arranged in 1,190 paragraphs and illustrated. Boards, 2 shillings, 6 pence.

This work attains its maximum value when a knowledge of how to use it is possessed by the reader. There are two indexes, the main index to be used when the fault is known and the cure is wanted, and the secondary index or tables are to be used when the fault is not known but merely the symptoms. At the end of the book there is a list in alphabetical order giving the principal symptoms which, if known, can be referred to directly and thus save the trouble of working through the tables which are arranged in the order of a genealogical tree. The list contains practically every trouble that can possibly be run into on the road and by the aid of the index there should be no trouble in hunting them down. When found, the proper paragraph will give some good, "meaty" advice as to the remedy for the trouble.

A SYNOPSIS OF THE ELEMENTARY THEORY OF HEAT AND HEAT ENGINES. By John Case, B. A., Published by W. Heffer & Sons, Ltd., Cambridge, England, and Simpkin, Marshall & Co., Ltd., London, England. Sixty-five 5 by 8 inch pages. Cloth, 2 shillings, 6 pence.

The student of gas engines should know his thermodynamics as he knows his A. B. C.'s. A knowledge of the laws of gases is absolutely required to design a successful expansion engine, and the same applies to the laws of heat. The problem now in gas engines is to secure a higher thermal efficiency and it is by the path of thermodynamics correctly applied that the conversion of losses into useful work will be accomplished. The gas engine is not a mere mechanical contrivance but it is an instrument for converting the energy contained in gas into useful work. This little work gives some useful problems in thermodynamics and employs some very direct methods in the solution of them.

HOW TO DRIVE A MOTORCYCLE. By Charles S. Lake, author of the *Motorcyclist Handbook*, published by Percival Parshall & Co., London, England, or Spon & Chamberlain, N. Y. Eighty-eight 4.5 by 7 inch pages; illustrated. Paper, 25 cents.

In this little pamphlet full directions regarding the operation and maintenance of a motorcycle are given. It is one of those little works which are of great convenience to a man who first takes up some such pastime as motorcycling, and who wishes to gain more than a superficial knowledge of the subject. Such a book as this is of almost unlimited assistance to the amateur.

The Engineering Digest

A Digest of Technical Information from the Engineering Journals

Effects of Taxation Toward Standardizing Small German Cars—Novel Pump Applicable to Automobiles and Fire Engines—Conversion of Cannel Coal into Liquid Motor Fuel

GERMAN 10-Horsepower Cars.—Owners of automobiles in Germany pay a tax of 80 mark (20 dollars) for a car of 10 tax-horsepower and 155 mark for a car of 11 horsepower of the same kind. A tax-horsepower is figured by the formula: $HP = D^2nL \times 0.3$. For this reason nearly all German manufacturers build a model which is sure to come within the 10-tax-horsepower rating. The motors have all four cylinders, excepting the Loreley which has six of 70 millimeters bore and 113 millimeters stroke. Nine out of the 24 four-cylinder cars have 80 bore and 130 stroke. These are the Adler, Apollo, Audi, Benz-Mannheim, Daimler, Komnick, Mathias, Nacke and Windhoff. The one first built in these dimensions was the Daimler-Untertürckheim in 1909. Adler and Windhoff at first built their 10-horsepower motors with 85 bore and 115 stroke but changed to the dimensions mentioned. The Hansa was changed from 85-115 to 80-130, but, curiously enough, the last models—1912 and 1913—are changed to 88-104. Beckmann, Brennabor and Protos have a motor of 82-123, N. A. G. and Phänomen one of 83-120 and Priamus and Opel 84-118. Opel formerly built their 10-horsepower motor with 80 bore and 130 stroke.

Benz-Ladenburg (meaning the cars built by Benz and his sons after the severance of their connection with the large works at Mannheim), Horch, Neckarsulm and Oryx constitute an important group in which the motors are 85-115. The two last ones have been made in these dimensions since 1907. Horch formerly built motors of 85-120, and the reputation of the firm was largely built up on these, but they gave 11 tax-horsepower, and so the stroke was shortened to bring them within the rating. In the Eisenach (87-110), Hansa (88-104) and Ehrhardt (90-100) the stroke is shorter than now ordinarily accepted in automobile motors.

Out of the 24 motors referred to 18, are cast in pairs and 8 in blocks, 9 have water-circulation pumps, while 15 have the thermo-syphon system. Komnick is the only one in which the radiator is behind the motor.

The thermo-syphon system is also employed in some larger German motors; in the Audi-Zwickau up to 22 tax-horsepower, in the Richard-Hering up to 25 and in the Bergmann-Metallurgique up to 29 tax-horsepower.

All the motors, excepting the N. A. G. and the Ehrhardt, which are of the T-type, are made with 1 camshaft. In 18 of them the valves are placed side by side. In 6 of them the inlet valves are of the pendent type; in the Mercedes, Horch and Windhoff these hang directly over the pistons and in the Audi, Komnick and Nacke over the exhaust valves. This is not a matter of fashion but renders it possible to have the combustion chamber of the most favorable compact shape.

The fuel feed is by gravity only in 6 cars; all the others have pressure feed. A still more pronounced standardization is noticed in the clutches, among which only 4 are of the multiple-disk type, all the rest being cone-clutches. All have 4 gear speeds, except Ehrhardt, with 3. Wheel base and gauge are fairly uniform. The longest wheel base, 3.23 meters, is found in the Opel car; the shortest, 2.90 meters, in the Eisenach. The latter also has the narrowest gauge, 1.26 meters, while Ehrhardt has the widest, 1.40.

In the Adler, the Komnick, the Protos and the Horch, tires of different dimensions for the front and the rear wheels are still used, although the contention that narrower front tires make

easy steering only holds good if the steering mechanism is faulty. The anthor has observed during an experience embracing much long-distance traveling for a number of years that when the tires on front wheels were changed—to take advantage of demountable rims—the broader tires did not affect the steering if the latter was otherwise right, while the car ran more pleasantly by reason of the softer suspension. Among the 20 cars in which front and rear tires are alike, the Benz-Ladenburg has the smallest dimensions, 810-90, and the Benz-Mannheim the largest, 820-120.

Matters relating to the gearing, the speed and the fuel consumption of the cars are exemplified in an appended table, giving the figures for 10 out of the 24. It is seen that the highest and the lowest gear in all the cars come close to the ratio of 1 to 4, while the intermediate gears are less uniform between these limits. As now well understood, the gears should be so chosen as to render it possible to utilize the motor at its best—say between 1200 and 1800 revolutions per minute—for all of them and for as wide a range of car-speeds as possible for each of them, so as to have as few gear changes as practicable. This requirement brings the ideal gear-reduction to 1 for direct, 1.6 for third speed, 2.5 for second speed and 4 for low. But if the reduction for low lies at 4.4, for example, instead of 4, the proportions become 1-1.76-2.75-4.4, and if the reduction for the low gear is only 3.6, the figures become 1-1.44-2.25-3.6. By comparing these ideal proportions with those listed, it is seen that all but Daimler and Benz-Ladenburg are geared too low for the second and third speeds.

The gear reductions in the rear axle range from 3.44 in the Nacke car to 4.5 in the Eisenach. The total reduction, as obtained by multiplying the change-gear reductions with the rear-axle reductions are found in columns 7 to 10 and vary, for the low gear, from 14.1 in the Benz Ladenburg to 19.8 in the Eisenach, while the variation on direct is identical with that given for the rear axle.

The interesting differences with regard to motor speed, car speed and fuel consumption may be studied directly from the subjoined table.—From article by Von Löw in *Automobil-Rundschau,* April 30.

—

MONIN'S Reversible Rotary Pump with Tight Joints—Among the rotary pumps which must be taken into consideration in the future for fire engines, for the water circulation in automobile motors and as a possible element in hydraulic power transmissions, clutches and kindred forms of mechanism, one recently invented by Charles Monin and described with all detail in *l'Ingénieur-Constructeur* for April 15 is based upon an entirely new principle by virtue of which it can snpport high pressures and high speed while acting as positively as any other piston pump, being in fact a rotary piston pump, like the Von Pittler *Rundlaufpumpe* used in some of the Berlin fire engines. It differs from the latter, however, in being more perfectly positive and therefore more reliable for drawing water from a lower level through an air-filled supply hose, or, in one word, as an evacuation pump. Its movable parts are balanced, this including the members which are only rotary and the two pistons whose movements are at the same time rotary and reciprocating.

Fig. 1 shows a diagrammatic section of this device together with a perspective view of the movable portion and, underneath, five consecutive positions of one of the pistons in relation to its rotary housing. The cylindrical casing B is closed in front and rear by two plates and is connected with the suction pipe A on one side and the discharge pipe R on the other. The body M can turn in the bore C of this casing and is formed with a recess across each of its faces, one at a right angle to the other, and in these recesses the two piston-blocks C and D, which are similar, can slide. The driving-shaft O passes eccentrically through the face-plates of the casing and through the middle of both piston-blocks but is formed in one piece with two eccentric enlargements extending in diametrically opposite directions and each constituting a cylindrical bearing for one of the piston-blocks.

When turning, the driving-shaft turns with it the two blocks and the body M, the lower portion of the illustration showing the positions successively taken up by the front piston-block and the body M during one turn of the shaft. It is noticed that the water is at first drawn in by the lower face of the piston and discharged by the upper. Then, as the parts are turned further around, in the direction indicated by arrows, the suction takes place at the left side and the discharge at the right. In the continuance of its rotary and also reciprocating movement the piston draws in water at the upper left and discharges at the lower right and then returns to its starting position—with the piston reversed, however. The piston and the body M thus make one-half of a turn when the shaft makes a full turn. The other piston effects a similar movement, following 90 degrees behind the first one. No valves being required, the operation is automatic without any other movable parts. The mechanism is reversible; that is, by changing the direction of the shaft-movement the flow of the water is reversed, and the supply and discharge pipes exchange functions. The possibility of operating this pump at very high speed without troublesome vibrations imparts to it a high capacity for its weight and size.—From *Le Génie Civil,* May 10.

—

BRITAIN'S Struggle to Evolve New Liquid Motor Fuels—It has long been the aim in English motor circles to emancipate the tight little isle from dependence upon imported gasoline and gasoline made from imported crude oil. A certain secretiveness, which apparently may be traced to the desire of patentees and promoters for securing an ample return for their labors and which has cropped out in the form of ambiguous or inconclusive statements of the results obtained, as well as in charges, countercharges and insinuations, is keeping the exact status of recent developments in this respect somewhat under cover. But it is known that one or two processes for extracting a liquid motor fuel direct from coal are under way and have advanced to such a point of feasibility as to place all older plans for utilizing alcohol or benzol completely in the shade for the present. While the new distillate from coal is frequently designated as benzol, it is not the benzol which has heretofore been turned out as a by-product of cokeries and gas works but a new liquid hydrocarbon resembling gasoline more than benzol in chemical composition and one which, unlike the real benzol, may be produced in practically unlimited quantity from poor grades of coal and from certain grades of shale.

It does not yet seem certain whether the product derived from coal differs materially from that derived from bituminous shale, especially as the coal preferred as raw material in England is shale-like in structure, while parallel experiments in France are directed upon the utilization of the shale there abounding.

A contributor to *The Motor,* a British journal which has been prominent in agitating the movement and describing the processes

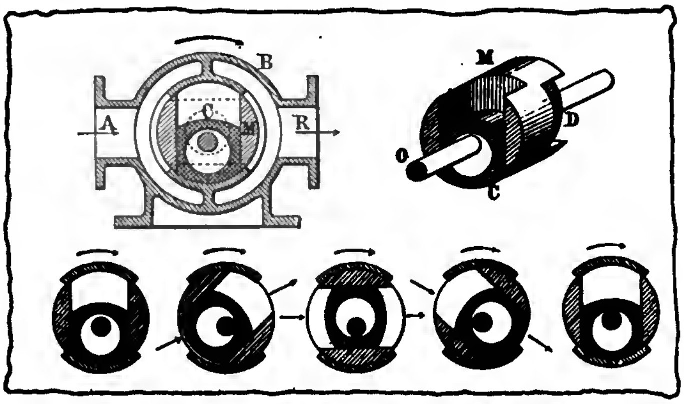

Fig. 1—Sectional view of the Monin rotary system pump, with perspective of movable parts and diagrams of operative stages

involved, summarizes the situation in the issue of May 13, as follows: "We are probably only at the beginning of a vitally important movement in the preparation of motor spirit from coal. But whatever process is arrived at, it is absolutely certain that there will be a considerable number of by-products, and on the profitable sale of these will depend the commercial success of the whole undertaking." The same contributer proposes the name of coalol for the new product so as to distinguish it sharply from benzol. The fact that benzol is a by-product in the utilization of valuable materials, while the coal distillate is a main product from fresh raw materials heretofore considered as of very low value and that the process of distilling it creates new by-products from these cheap materials, perhaps of greater value than any which the raw materials were supposed to contain, apart from the value of the new main product, evidently establishes a contrast which warrants the search for a new name. [The name of coalol, however, does not seem very acceptable from any point of view, being of hybrid derivation, too close to "coal oil" in sound, and lacking in the vigorous individuality always eventually wanted for an important article intended for popular consumption. Perhaps "canneline" would come nearer to the requirements, in view of the derivation of the new fuel from "cannel coal."—Ed.]

The process for converting coal into motor fuel, plus by-products, of which most details have become known is one identified with the name of Del Monte as inventor. With special reference to the results of this process, the authority quoted above states that the products gained by the decomposition of the coal range as follows in market value: (1) Solid fuel similar to coke, 56 per cent.; (2) gas, which may be sold or used as fuel in the cycle of the distillation itself, the quantity not yet determined; (3) motor fuel 20 per cent.; (4) heavier oils .04 per cent.; (5) sulphate of ammonia 10 per cent. and (6) tar or pitch 8 per cent.

From this accounting it is plain that the motoring public will buy only $20 worth out of every $100 worth of product brought into existence by the contemplated new enterprise, and that consequently the public in general must be relied upon for finding suitable uses for the rest of the production. Assuming that the minor products may be readily disposed of, the great commercial problem which must be solved before the motoring public can get the benefit of the "coalol" [or "canneline"] is therefore to stimulate the at present languishing demand for a smokeless coke-like fuel for domestic or industrial purposes.

Another great difficulty to be overcome, it is stated, lies in the transportation problem of the new materials which is hedged with legal provisions said to favor prospective competitors.

The nature of the Del Monte process is described in *Omnia* of April 12 by J. Marsillac, a French observer who was present at some of the tests which have been conducted in a semi-public manner. According to his account, the motorists of the British islands consume at present more than 400 million liters of gasoline per year, and the Del Monte process promises to satisfy all of this demand, because it extracts from 20 to 30 times more liquid fuel from coal than could be extracted by the established methods used in the production of benzol. The latter is made by placing the coal in a vat which is heated

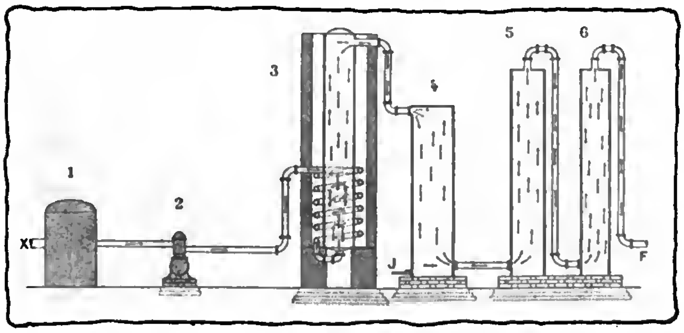

Fig. 2—Sketch of Del Monte plant for producing liquid motor fuel from cannel coal and other inexpensive materials

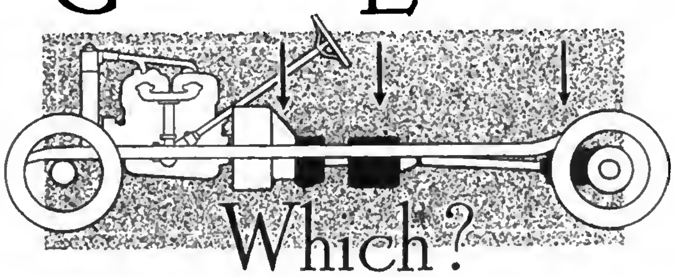
from the outside to about 1,000 degrees Centigrade. Illuminating-gas and a whole series of volatile products are in this manner driven out, and the volatile products are successively condensed. From one of them the benzol is obtained by refinement. The residue in the vat is the ordinary coke employed for different heating purposes. The system of heating from the outside alone entails a great waste and a lack of uniformity in the products, as those coming from the interior of the heated mass have not been subjected to nearly as much heat as those coming from near the walls. By the Del Monte method the temperatures imparted to the coal rise nowhere much above 500 degrees but are applied in the interior as well as to the exterior of the mass of treated material. The operation is a cycle in which the products of the distillation at one stage in the process are utilized for the other stages. The apparatuses used are placed in a circle and connected, so that the operation becomes nearly automatic and wholly continuous. Fig. 2 represents the different parts as placed in a row, for the sake of clearness, but in reality the pipes X and F are connected. With reference to the illustration, the plant comprises (1) a gasometer, (2) a compressor pump, (3) a retort of special construction, (4) a condenser with drain pipe at J and (5 and 6) two scrublers, or combined washers and condensers of gases. The retort is composed of a metallic receptacle slightly conical, with the taper toward the top, where a gate may be opened for the reception of coal from an automatic charging apparatus and hopper. At the bottom another gate serves for the removal of the coke. At about one-third of the height of this retort, a pipe from the compressor-pump enters through the side of the surrounding wall, carrying gas under slight compression. This gas is at the start ordinary illuminating-gas, with which the gasometer is charged, but subsequently the gases generated by the process take its place. The pipe follows a serpentine course to the bottom of the retort where it enters the latter. It is heated externally by means of Bunsen burners, the arrangement of which may be readily imagined, and the retort naturally receives a great deal of heat from the same source. The pipe and the gas contained in it is raised to a temperature of about 800 degrees, and when this hot gas is discharged at the bottom of the coal it rises rapidly heating the coal uniformly. All the gaseous products driven out of the coal, and among them those containing the new motor fuel, rise to the top of the retort and from there reach the condenser (4), from which some of those with the highest flashing point are drained. The others continue their course to parts 5 and 6, where they are "scrubbed" and liquefied. Only a few non-condensable gases are returned to the gasometer, from which they are sent out in the circuit again as heat producers.

Among the different sorts of coal which may be used in this plant the variety known as cannel coal gives the best economical results. It looks like very dark shale but is rich in the constituents formerly desired for illuminating gas. But it has now been abandoned for this purpose in favor of other coals of higher caloric value. Its combustion in fireplaces develops smoke and odors which render it undesirable as a domestic fuel. For these reasons the price of it has dropped to $1.25 per ton, and large deposits of it are available in Scotland. From a ton of this material the Del Monte process produces 200 liters of motor fuel in some instances. The estimates mentioned in connection with the projected enterprises are much lower, however, the probable price of the coal being placed at about $3.25 and the output of motor fuel per ton of material at 40 to 60 liters, whereto comes 700 to 800 kilograms of coke which burns with a clear and smokeless flame, 14 to 20 kilograms of sulphate of ammonia and up to 200 cubic meters of gas.

The flashing point of the new fuel varies from 50 to 150 degrees C., while that of benzol varies from 80 to 110 degrees and that of gasoline from 47 to 110 degrees. The specific gravity is 746 at 14 degrees C. The product does not attack or foul cylinders or pistons, and a motor may be started with it as easily as with gasoline.

The Engineers' Forum

Gearbox Location



Part V

Positive Alignment of Gearbox and Engine Argument for Unit Motor

THIS week appears the opinion of one of the few engineers whose views on the subject of gearbox location have not been published in THE AUTOMOBILE to date. Another engineer writes regarding stock car racing and its effect on the public and a third gives his ideas on the subject of horsepower rating.

Unit Type with Three-Point Motor Suspension—Klinger

DAYTON, O.—Editor THE AUTOMOBILE:—With reference to our opinion of proper location of gearbox, we are very pronounced in our preference for three-point suspension of the motor with a unit gearbox. This insures a positive alignment of gearbox and engine, not only in the assembly of the car, but also the maintenance of this alignment in years of service. It also makes it possible to absolutely inclose the clutch and operating parts, making it possible to lubricate them properly and exclude dust and dirt, thereby largely eliminating the wear and tear.

This location of the gearbox also eliminates a number of parts, such as rods, levers and pins which are necessary with the amidship location as well as rear-axle location, and the elimination of parts on an automobile usually means a decided step toward the elimination of trouble and expense as well as weight.

The unit plant certainly is much more accessible than the rear-axle plant and equally as accessible as the mid-ship location. While trouble does not often arise with gearset these days, yet were one to attempt to look into the gear of a rear-axle transmission on the road he would be quickly convinced that either the mid-ship or the unit plant is much more desirable location. It is necessary to inspect these gearsets occasionally to see that they are oiled, and we believe the rear-axle location is not nearly so likely to receive attention as unit or amidship. Each day's experience with the unit power plant only tends to confirm our very decided preference for it.—P. W. KLINGER, Chief Engineer, Speedwell Motor Car Co.

Stock Cars Are Not Fit for Racing Purposes—Porter

TRENTON, N. J.—Editor THE AUTOMOBILE:—I note in a recent issue of THE AUTOMOBILE that the stock car racing bee is at large and has evidently stung a few people. The different opinions expressed as to the value of this type of racing is, to my mind, offered without a perfect analysis being made as to the conditions involved. I wish to appeal to you to use every possible effort through the columns of your paper in an endeavor to stop this question gaining any momentum at this time. To my mind, this is one of the greatest impositions ever perpetrated on the public and it surely gives the manufacturers a great amount of trouble from which they get no return whatever.

The several expressed advantages for stock car racing do not express at all clearly the real facts governing the situation. In the first place, a stock car is not fit for a race nor is a racing car fit for stock use. Then, besides, it seems so unreasonable for any reputable firm to be parading its wares in front of the public, shouting continually that they are honest goods. My impression is that this is a position that should be at least assumed by all manufacturers of standing and one that is, I believe, conceded by the public, or, at least, should be. There is no real reason why the manufacturers should not incorporate in any stock car their most earnest and honest efforts to produce a product free of trouble, especially since it is much cheaper to make one's product good in the beginning, than it is to maintain an expensive and elaborate road department in order to keep the car running. I believe the public thoroughly understands this and when any firm can demonstrate its ability by producing a speed creation capable of record-breaking performances it is reasonable to suppose that the experience gained will be used to better the stock production. Besides, the general principles are involved just as much in racing machines as they are in stock cars. The basic principles are the only ones at stake in either of them. Consequently, my impression is that when you find a man howling about stock car racing you will have one not capable of producing a speed creation. In other words, he knows his production is not what it should be, but he wants to try to convince the people that it is. No purely stock car ever won a race or ever will as long as the conditions involved are so entirely different from those demanded in stock car use.

Aside from the reasons given above, it is almost impossible to promote a stock car race, as the public is not at all interested in any competition unless its very nature promotes thrills beyond the possibility of a stock car. This fact alone leads to all sorts of inducements being offered to swell an entry list and necessarily permits the entry of a great many cars not at all fit for the purpose, which only makes a farce out of the proposition.

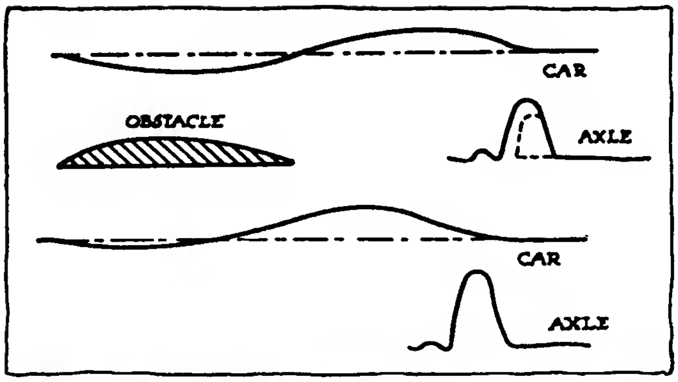
In view of the conditions involved, I urge upon you the necessity of opening and keeping open a thorough discussion of these points, so that it will be kept continually before the public.
—FINLEY R. PORTER, Engineer, Mercer Automobile Co.

Manufacturer Could Give Both S. A. E. and Own Rating

EAST MOLINE, ILL.—Editor THE AUTOMOBILE:—The manufacturer of a long-stroke motor has been forced to give actual horsepower rating and not the A. L. A. M. rating on account of the fact that he is not getting any credit for the gain in the longer stroke against the manufacturer that is putting out a shorter-stroke motor.

On the other hand, the manufacturer of the long-stroke motor will, as a rule, gear his car high enough to work only with a modern engine speed on the average road, consequently the power developed will not be any greater than the power developed by the short-stroke engine at the same car speed but higher engine speed.

We believe that the A. L. A. M. or S. A. E. ratings should not be abolished, but the manufacturer could, perhaps, give the public both ratings; the rating of the standard formula as well as the rate of the actual average horsepower that the motor is capable to develop. This is the practice of many European manufacturers. They will give the tax rating and the actual rating.—E. GRUENEWALD, Moline Automobile Co.



Figs. 1 and 2—Sample records made by model car, the obstacle being a bent piece of thin steel of the actual shape shown

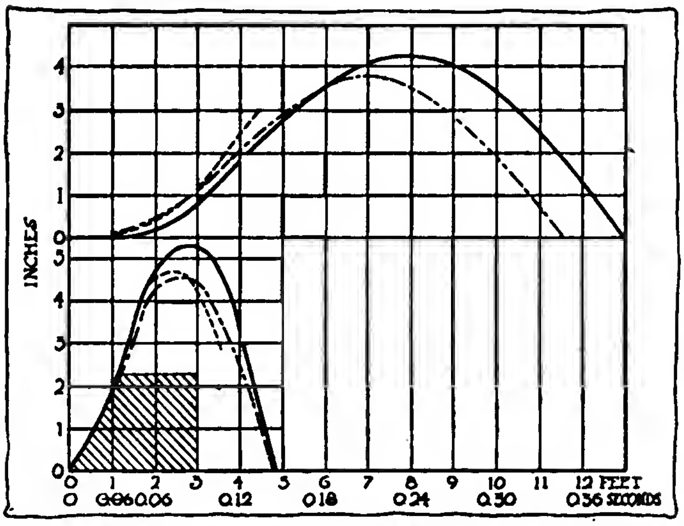


Fig. 3—Showing in full-line curves the motions of the axle and car with no friction. Note how closely the curves agree with those obtained by the use of the model

Defects in Springs

Use of Shock-Absorbers Indicates That Present Construction Leaves Much To Be Desired in Comfort

From a Paper Read Before the Institution of Automobile Engineers by G. H. Baillee

AUTOMOBILE springs have received less attention from those who talk and write than any other part of the car. I do not know whether those who do things have been equally neglectful, but they have been remarkably silent about what they have done. A hunt through the automobile literature has shown practically nothing of interest, apart from the question of the qualities of steel suitable for springs. An examination of the practice in cars now on the market shows that, with two or three exceptions, all springs are of the same pattern, neglecting differences too subtle for the ordinary observer. The most notable exception is due to the man who has introduced more novelties into motor cars than anyone else, and, unlike most other novelists, has introduced successful novelties.

I was first induced to commence investigations on the subject of springs by owning a car which was peculiarly uncomfortable to ride in. The next impulse towards an endeavor to find out something about springs was the rage for auxiliary springs and shock-absorbers. At the present time it is rare to see a car without a fitting of this kind, a fitting not belonging to the car but stuck on to it. Now, unless it is assumed that the utility of all these things is entirely imaginary, their existence is a grave reflection on chassis builders; it means that the makers have not done their best in springing the chassis, and have left room for improvement, and if any improvement can be effected by an owner by casually putting on the first contraption he sees advertised it means that the room for improvement must be very large.

Springs Are Now Most Important Feature

Some makers certainly have given a great deal of thought to their springs, and the results can be felt in their cars; but the author knows others, and he believes their number to be large, who do not give the springs anything approaching the attention they deserve. Now that cars have given up breaking down, I consider their springing the most important feature. It is only necessary to run for a few hundred miles over a flat, dull and bumpy road to realize how much the pleasure of the trip depends on the springs.

And something more than comfort depends on it. The author believes that tires are more affected by the action of the springs than by anything else, both as regards wear and bursting.

I started by constructing a model car to one-eighth linear scale, having wheels with solid rubber tires. For convenience I made the road move under the car, the road consisting of a strip of webbing 12 feet long, passing round a motor pulley and an idle pulley. The webbing ran over a board where the car rested on it. After trying a front and back wheel, I discarded the front wheel and retained only a single wheel on the end of an axle pivoted some way back, so that the wheel had an approximately vertical motion.

Fig. 9 shows the arrangement of the model and its equipment after the second wheel had been removed.

To the axle was fixed the lower leaf of a double elliptical spring made of two single pieces of clock spring, the upper leaf being fixed to a framework and also pivoted some way back.

The framework, which represented the spring portion of the car, had provision for carrying load. Pencils were fitted to the car and to the axle and recorded on a moving strip of paper.

Obstacles of different kinds were attached to the road, and frictional devices were attached between the axle and the car.

Figs. 1 and 2 show two sample records, the obstacles being a bent piece of thin steel of the actual shape shown. According to the linear scale of the car, the obstacle would be 2 inches higb to a full-sized car.

It will be noticed that the wheel jumped above the obstacle in each case and came to the ground beyond the obstacle, and the shape of the obstacle appeared to make no appreciable difference unless its slope was very gentle.

It will also be noticed that the wheel reaches the top of its path before the car has moved appreciably, and by the time it has returned to level ground the car has completed only some 40 per cent. of its upward path.

In Fig. 1 no friction was introduced to damp the oscillations, the amount of damping being actually about the same as that which exists in an ordinary leaf spring. In Fig. 2, in which the track speed was about double, friction was introduced, and the damping effect is very noticeable in the rebound of the car.

No Difference in First Half Oscillation

Now, examination of a considerable number of records, without friction, with constant friction and with friction increasing with the amplitude, showed no appreciable difference in the first half oscillation of the car, and in this respect the model car was most disappointing. It became clear, in fact, that the difference lay in the initial movement of the car, while the axle was rising, and, in the model records, this part of the curves was on too small a scale to admit of accurate examination.

I then reckoned out the motions of the axle and the car on meeting an obstacle, making certain assumptions in respect to the obstacle to circumvent the difficulties which arise while the tire is "drinking the obstacle." The resulting curves are, as far as comparison is possible, of the same type as those given by the model, and this leads him to hope that the calculated curves do show what actually happens.

Fig. 3 shows in full line curves the motions of the axle and the car with no friction, and it may be noted how closely the curves agree with those from the model.

The assumption made in regard to the obstacle was that it was of a shape to give a constant pressure on the tire, and the pressure assumed was that required to flatten the tire till 40 square inches of tire with 85 pounds of air pressure were in contact with the obstacle. This is approximately what happens with a large section tire. The obstacle is 2.25 inches high and the tire is in contact with it for 14 1-2 inches. The author assumed a car with 750 pounds sprung weight per back wheel and 250 pounds unsprung weight, including the weight of the spring, a spring deflecting 1 inch per 200 pounds, and a velocity of 22.5 miles per hour.

It had to be assumed that the tire left the top edge of the obstacle suddenly, and released the pressure suddenly, but this point does not show any break of continuity on the curves in Fig. 3. The abscissæ of the curves are feet of travel of the car and the ordinates inches of rise. It has been assumed that there is no rebound of the axle from the road.

Now, the path of the car, as shown in the curves, is not really of much importance. So long as the maximum movement does not pass the limit reluctantly allowed by the coachbuilder, a large swing causes no discomfort merely because it is large. In crossing a humped bridge at just the right speed, there is often a very big swing with a gentle switchback movement and no sign of a jerk.

The full line curve in Fig. 4 is the acceleration curve of the car, corresponding to the curve of path in Fig. 3, the curve being plotted from the calculated figures, and not deduced from the curve of path. In this figure the abscissæ are feet of travel, as before, and the ordinates accelerations, those above zero being upward accelerations. The maximum upward acceleration is reached just before the axle reaches the top of its path, and the acceleration changes sign just before the axle returns

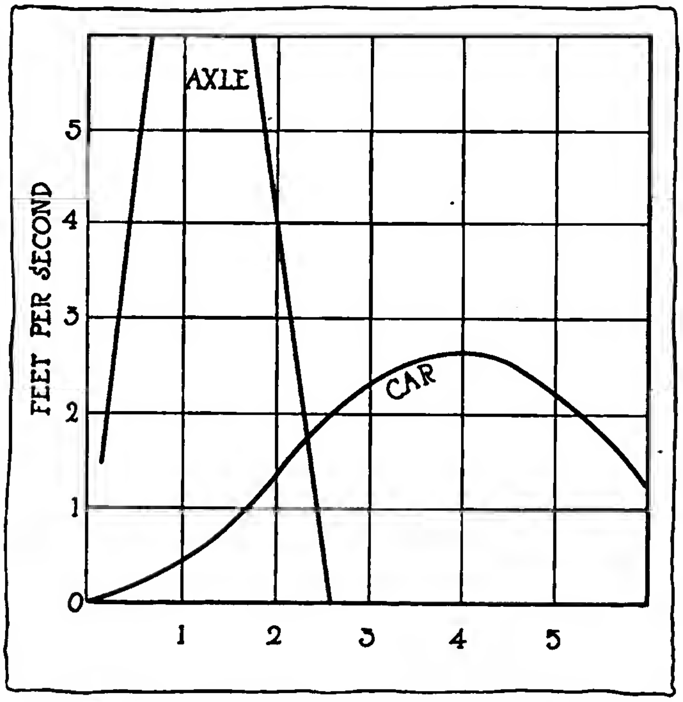

Fig. 5—Enlarged curve, showing comparatively the motion of the car and axle in passing over an obstacle

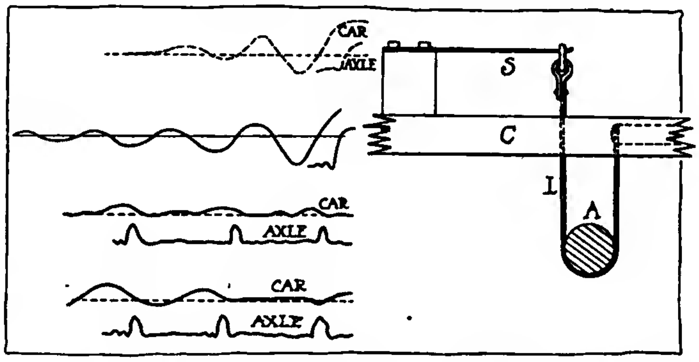

Fig. 6—(Upper left), two graphs of a 15/16-inch drop of the car fitted with the friction device and with the road stationary. Fig. 7— (Lower left), two graphs with the road running and three obstacles at equal distances. Fig. 8—(Right), special friction device fitted to model car in which the friction element consists of a leather band acting against the axle on the rebound when the axle passes beyond its normal position

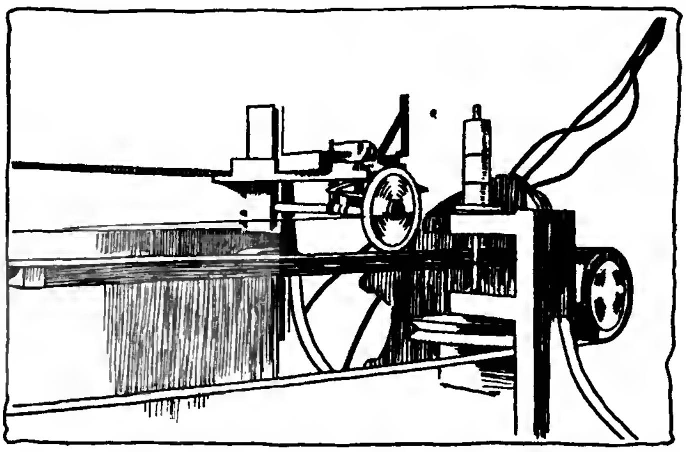

Fig. 9—Model car, constructed to one-eighth linear scale, and roadbed formed by belt running on pulleys actuated by an electric motor. An obstacle is shown at the middle of the upper part of the belt. In the operation of the device, the wheel and the axle are stationary, the moving roadbed imparting the shocks recorded through the spring

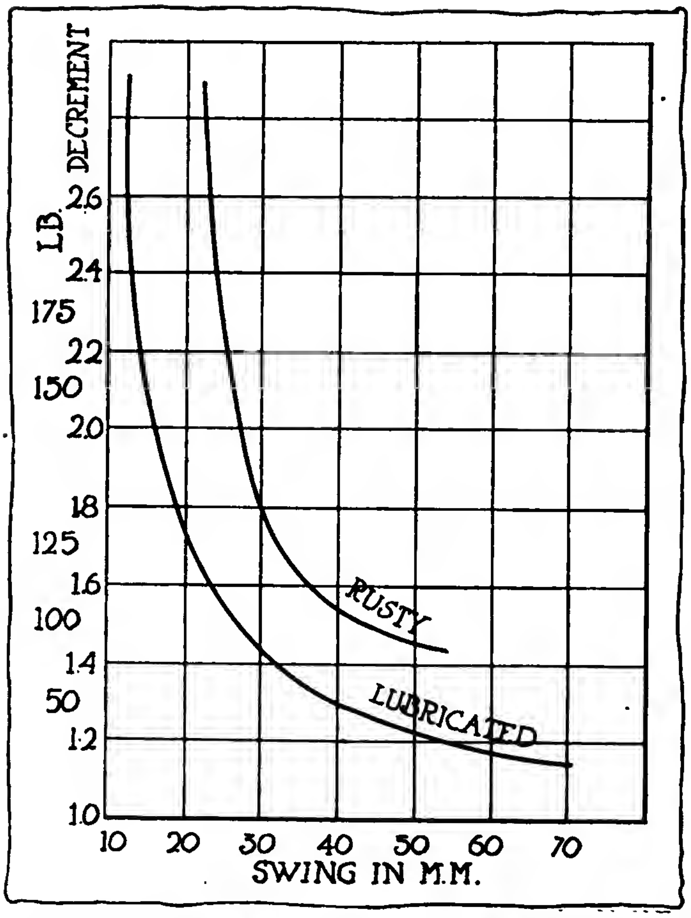

Fig. 10—Curves plotted from a number of records. It is remarkable how rapidly the decrement (ordinates) increases as the oscillations decrease

to level ground. After this point the car executes free harmonic motion up and to the end of its travel, and the acceleration curve is a sine curve.

The broken line curves in Figs. 3 and 4 are corresponding curves to the full line curves, with the one difference that the strength of the spring is 300 pounds per inch instead of 200 pounds. The whole movement is over sooner, but otherwise there is little difference to be seen in the curves of path. Turning, however, to the acceleration curve, this, at the corresponding point, is markedly steeper. The maximum inclination is 48 ordinate per unit abscissa, or 50 per cent. more than with the weaker spring. The inclination is in the same proportion as the strength of the spring, and this clearly shows the importance of having a spring no stronger than is necessary.

The dot and dash curves in Figs. 3 and 4 correspond to the full line curve, with the single difference that friction has been assumed to exist in the relative motion of car and axle. The friction has been assumed constant and equal to a force of 170 pounds. To give an idea of what this means in practice, it may be said that the friction in an ordinary seven-leaf spring tested by the author was, when clean and well greased, about 50 pounds, and when rusty about 85 pounds, these values being obtained by measuring the decrements, which were 1.24 and 1.45 respectively. Now, the author does not know what friction shock-absorbers are supposed to give. After a few months on a car the friction is generally negligible, but when new he presumes they have a fair amount. The frictional force of 170 pounds he has assumed is not, therefore, out of the way for a spring in average condition fitted with a shock-absorber.

The fluid friction device appears to be an excellent thing, and the only trouble about it is that, as far as I know, it will not work in practice.

The other kind of friction device is that which comes into action only on the rebound. My assistant, Mr. Gregory, designed a very ingenious form of this, which he fitted on the model car. It is shown in Fig. 8, in which A is the axle, C the car and L a leather strip fixed to the car at one end, passing under the axle and hanging at the other end on a spring S, fixed to the car. In the normal position of the spring, the leather band is quite free, the spring S exerting no force on it. Therefore, for any compression of the spring from its normal position no friction is introduced. On the rebound, however, as the axle passes beyond its normal position, it comes against the leather band, which rubs round it with pressure increasing with the rebound deflection.

Fig. 6 shows two graphs of the model car fitted with this device taken with the road stationary, merely by dropping the car through 15-16 inch. The lower graph represents the undamped swings, the upper graph shows the result obtained with the leather band.

Fig. 7 shows two graphs taken with the road running and with three obstacles at equal distances, the speed being adjusted to make the effect of the obstacles cumulative. As before, the lower graph represents the undamped swings and the upper graph the effect of the leather band.

I will now mention some tests made on a motor car spring which was very kindly lent to me by the Wolseley Co. It was a light spring, deflecting 1 inch with about 135 pounds, and was 49 inches long, and had seven leaves. This was hung by its ends on two long shackles, and a platform was hung from its center to take weights. Weights up to 690 pounds deflected the spring till it was nearly flat, the height above the chord being only 16 millimeters. A pencil attached to the center of the spring recorded on a drum. The spring was made to oscillate by hand, and at the moment the hand was removed the pencil was put in contact with the drum upon which the records were taken.

For the first tests the spring was cleaned and well greased, and then the grease was thoroughly cleaned off and strong sal ammoniac put between the leaves, with the result that in a day the spring was as rusty as the ordinary motor car spring generally is.

From the graphs obtained, the decrement was measured as the ratio of one half-oscillation to the next half-oscillation. The ratio of the positive amplitude to the negative was not taken because the zero position, owing to friction, was not quite definite. Fig. 10 shows curves plotted from a number of records, the abscissæ being the total amplitude, plus to minus, of the first half-oscillation from which the decrement (ordinates) was reckoned. It is rather remarkable how rapidly the decrement increases as the oscillations get small.

To gain an idea of what the decrement means in friction, the average frictional force over a swing was calculated by equating the loss of energy in the system over a whole oscillation to the work done by the movement of the center of the spring. The frictional force so calculated would be that in a friction device attached to the center of the spring if the spring itself were without friction. The second scale of ordinates gives this force in pounds. The difference between the two conditions of the same spring is very striking, especially when it is remembered that the deflections are small ones in a nearly flat spring. Thus, for a total swing of 24 millimeters the frictional force is 100 pounds in the lubricated spring and 175 in the rusty one. For a larger swing of 54 millimeters they are 46 and 83 pounds respectively.

It would be interesting to ascertain the difference in friction between a flat spring and a highly cambered spring, but it would mean the construction of a number of different springs. I took a number of graphs with a weight of about 380 pounds with which the height of the chord was 80 millimeters instead of 16 millimeters with 690 pounds. The resulting curve is of the same shape as those in Fig. 9, but the decrements are lower. For a swing of 30 millimeters, with lubricated spring, the decrements are 1.253 and 1.420 for 380 and 690 pounds, respectively. I do not think, though, that any deduction can be made from these results to give an indication of the difference in friction due to camber only.

Benzol Beats Gasoline in Economy Test

Trials with Favorit Carbureter on Brooklands Show Saving of 17 Per Cent. in Miles Per Gallon

Economy of Benzol Was Particularly Noticeable at Low Speeds, Giving 33 Miles to the Gallon as Compared to 26 Miles with Gasoline

LONDON, ENG., May 20—Benzol gives better fuel economy than gasoline, according to the reports on the Favorit carbureter just given out by the Royal Automobile Club and published in the *Journal* of that institution. The carbureter was fitted to a Benz 28-35-horsepower car and the trials were held on Brooklands track. The speed of the car was noted and the amount of fuel consumed recorded in terms of miles per gallon. An average of the tests showed that the benzol was 17 per cent. more economical in miles per gallon than the gasoline. The difference in economy was particularly noticeable at low speeds, as may be seen from the tables, where the car attained a mileage of over 33 miles to the gallon on benzol as compared to 26 miles per gallon for gasoline. The full report as given by the R. A. C. is as follows:

This is to Certify that a Favorit carbureter was entered for trial by Messrs. Favorit Vergasergesellschaft m. b. H., of Berlin, and 14 Caxton House, London, S. W.

Description of Carbureter—The carbureter is of the usual form, with float chamber and mixing chamber. There are two sources of fuel supply to the engine: (*a*) The usual central jet (which is adjustable by a taper needle); (*b*) a by-pass entering the induction pipe at the point at which the lip of the butterfly throttle touches. In addition, air is admitted to the engine through the throttle spindle when the throttle is completely closed and the engine not firing.

Description of Trial—The carbureter was fitted to a 28-35 horsepower (22.4 R. A. C. rating) Benz car. The carbureter was warmed by the engine cooling water. The particulars of the car were as follows:

Engine, four cylinders	95 mm. by 140 mm.
Volume of the compression space of a cylinder	293 c.c.
Volume swept by the piston	991 c.c.
Compression ratio	4.3
Weight of car	3,626 lb. (32 cwt. approx.)
Weight of car and load as run	4,181 lb. (37⅓ cwt. approx.)
Gear ratio on top gear	3.25 to 1
Size of wheels	880 mm.
Wind area of body	14.0 square feet
Country of origin of carbureter	Germany

The trials were held upon Brooklands track. The weather for Tests 1 to 7 and 13 to 17 was fine, cold and windy, while there was rain during 8 to 12.

Benzol was used in Tests 1 to 12, the following being the result of a distillation test of a sample:

First drop distilled at	75 ° C.
10 per cent. distilled at	84.5° C.
20 per cent. distilled at	85 ° C.
30 per cent. distilled at	86 ° C.
40 per cent. distilled at	87 ° C.
50 per cent. distilled at	88 ° C.
60 per cent. distilled at	89 ° C.
70 per cent. distilled at	91.5° C.
80 per cent. distilled at	94.5° C.
90 per cent. distilled at	103.5° C.

The specific gravity of the fuel, which was 0.873 at 15.5 degrees Centigrade, may indicate the presence of an extremely small quantity of gasoline, so small as probably to be caused by imperfect draining of the tank and pipes prior to filling up with the benzol.

After Tests 1 to 7 the carbureter was adjusted and the valves of the engine ground in. No adjustment or alteration was made between the tests in which benzol was used and those in which gasoline was used.

SUMMARY OF TESTS

No. of test	Fuel used	Speed, m.p.h.	Consumption — Miles per gallon	Consumption — Ton miles per gallon
1	Benzol	13.17	19.5	36.4
2	Benzol	18.85	19.5	36.4
3	Benzol	25.99	18.77	35.03
4	Benzol	31.41	17.55	32.75
5	Benzol	38.45	17.55	32.75
6	Benzol	44.02	17.55	32.75
7	Benzol	48.79 (Maximum)	15.59	29.09
(The carbureter was then adjusted)				
8	Benzol	13.35	33.40	62.34
9	Benzol	19.31	30.44	56.82
10	Benzol	25.10	28.63	53.44
11	Benzol	31.12	26.52	49.51
12	Benzol	37.17	21.67	40.44
(Higher speeds were not attempted by the entrant)				
13	Gasoline	13.53	26.57	49.60
14	Gasoline	19.21	25.30	47.22
15	Gasoline	25.21	23.93	44.67
16	Gasoline	32.01	22.36	41.74
17	Gasoline	36.45	20.68	38.60

(Higher speeds were not attempted by the entrant)

NOTE.—The speeds are average speeds, hut were kept as constant as possible during each test.

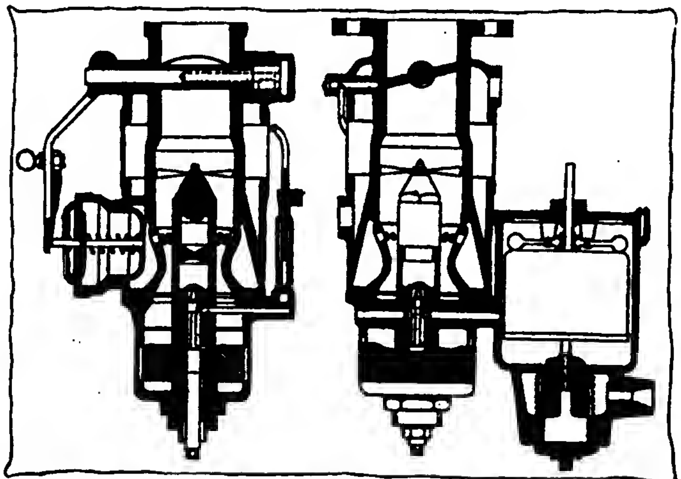
R.A.C. Tests on Globe Car

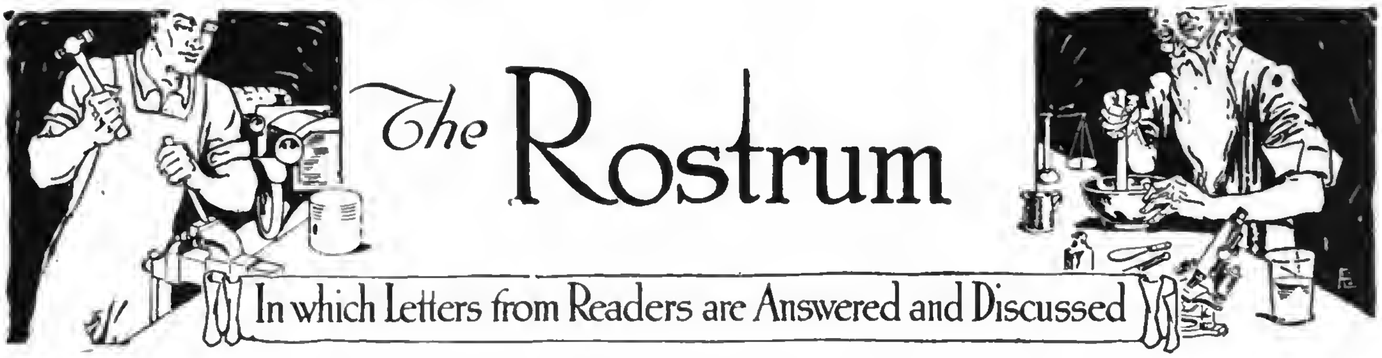
LONDON, ENGLAND, May 20—Reports just published by the Royal Automobile Club on the tests of a Globe car on the roads between Russell Court and Bow Road, London, for the purpose of determining the performance of the car under traffic conditions, show English car performance on high gear.

The car weighed 1,300 pounds in running condition and was equipped with a two-passenger body. The motor was of French manufacture with a bore of 4.13 inches and a stroke of 4.72 inches, has one cylinder and has a gear ratio of 4 to 1 on high. The route followed was between Russell Court, St. James and Bow Bridge. This takes in some of the heaviest traffic streets in London. The trial was started at 8 a. m., and ended at 1.30 p. m. The total distance covered was 46.4 miles. There were voluntary stops of 6 minutes and 58 stops for traffic totaling 23 minutes and 36 seconds. The average speed was 8.3 miles per hour. The car was started and driven on high gear only. After the luncheon period it was found that the car could not be started owing to a sticking exhaust valve.

A second test over the same route was made with this car a week later during which time the car covered 79 miles at an average rate of 10.7 miles an hour. During the test there were 113 stops all being voluntary.



Transverse and longitudinal sections through Favorit carbureter



No Taxation on Horse-Drawn Vehicles—Fire Department Collects Fees—Correct Place To Put Gearset—Development of the Cyclecar—Correction on Tax Laws—Bad Mesh Causes Gear Growl

Horse-Drawn Vehicles Are Not Taxed

EDITOR THE AUTOMOBILE:—Is there any law in the United States by which the horse-drawn vehicles pay a tax, the same as automobile owners? As you will see by the inclosed clipping, Colorado passed a law imposing a tax according to horsepower upon automobiles, and I consider it class legislation to tax one vehicle and not another, and will fight paying my $10 a year automobile tax after July 15, 1913, if I have a precedent to go by, as I already pay personal taxes on same, and heretofore we have been only paying $2 for a registration license and got a number and no more tax, except for personal property each year.

If you put me on the right track of someone who knows or tell me what has been done in other states, I will appreciate same, as I feel we automobilists are being unduly taxed.

Denver, Colo. W. L. H.

—THE AUTOMOBILE does not know of any state where horse-drawn vehicles are taxed in the same sense that motor cars are taxed for registering purposes. There are states where horse-drawn vehicles are compelled to pay a wheel tax the same as motor cars, but not to my knowledge a state where a registration fee is charged for horse vehicles.

This registration of motor vehicles beyond the cost of identifications is purely a double taxation matter as we have expressed from time to time.

As you are no doubt aware, the American Automobile Association is going to contest this matter in the Courts and take it to the Supreme Court in order to decide whether the present method of registration is legal or not.

Average Speed on a Tour of 2 Weeks

Editor THE AUTOMOBILE:—I am planning a vacation tour of 2 weeks in my car. In making my plans for this tour by the aid of a road map I have counted on averaging 20 miles an hour throughout the trip. During each day I am counting on making 120 miles in 6 hours as I intend traveling from 10 a. m. until 5 a. m. with a stop-off of an hour each day for dinner. At this rate, I will just finish the trip I intend making. The roads are for the most part very fair. Is this average about right? I do not want to travel more than 6 hours a day as I desire time for other recreation.

Cleveland, O. VACATION.

—You will have no trouble in making 120 miles a day over fair roads but you will find that unless you travel uncomfortably fast for a tour you will never average 20 miles an hour. It has been found that the many times it is necessary to slow down on account of villages, hills, curves, tire repairs and the various other likely causes that the average touring speed is close to 15 miles an hour.

Has Authority to Collect Automobile Fees

Editor THE AUTOMOBILE:—Has the Fire Department, Division of Combustibles, authority to collect $5 per year for a permit to keep an automobile?

Flushing, L. I. A. H. W.

—The law on this subject is printed in the regulations of the Municipal Explosives Commission adopted January 3, 1912, governing the storage and use of mineral oils, inflammable mixtures, combustibles mixtures, garages, motor vehicle repair shops, etc. Section 372 of the laws states that: "A permit may be issued for a garage on premises on which there is a dwelling occupied by the applicant or by his employee, provided that the entrance to the living apartment shall not be through the garage; and provided further that all motor vehicles stored or kept therein shall be the property of the applicant or of his immediate family, and that none of such vehicles shall be let out for hire."

Section 373 states: "A permit may be issued for a garage in a building occupied as a dwelling by either the applicant and one other tenant or by the applicant's employee and one other tenant, provided that not more than two floors or stories above the garage are occupied or used as living apartments, which apartment shall be separated from the garage by unpierced fireproof walls and floors; and provided further that all motor vehicles stored or kept in such garage shall be the property of the applicant or of his immediate family and that none of such vehicles shall be let out for hire."

In regard to fees, to quote section 101—"For a permit allowing the maintenance and operation of a garage as provided for in section 372 and 373 of these regulations, the applicant shall pay an annual fee of $5 for a single motor vehicle stored therein and an additional annual fee of $2 for each additional motor vehicle so stored."

A. L. A. M. Rating Known as the S. A. E.

Editor THE AUTOMOBILE:—I know how to figure the A. L. A. M. rating, but would like you to explain the S. A. E. and R. A. C. ratings and any other rating that may be used. Kindly explain same in such a manner that I can take my pencil and figure the horsepower after knowing the bore and stroke.

2—What is the proper horsepower for a car weighing 4,600 pounds with full equipment and tanks filled?

Morgantown, W. Va. B. H. MADEIRA.

—1—When the A. L. A. M. passed out of existence the old standards which had been adopted by this body were in a way wished upon the S. A. E. because it is part of the work of the Society of Automobile Engineers to standardize the measurements of all fittings. The A. L. A. M. spark-plug thread, for instance, which was adopted by that body, has now passed over to the S. A. E. which has adopted it as their standard. In the matter of the horsepower formula the old A. L. A. M. formula has become to be known as the S. A. E. rating, although there is no official record on the books of the Society of Automobile Engineers to show that they as an institution have adopted the A. L. A. M. formula as their own. The R. A. C. is at present using the same rating that we know as the A. L. A. M., that is:

$$\text{Brake horsepower} = \frac{D^2N}{2.5}$$

In this formula D represents the bore of the motor, N the number of cylinders and 2.5 is a constant for all four-cycle automobile motors.

2—It is impossible to state what the proper horsepower for any given car weight should be because it depends upon where it is going to be used. It is evident that in the weight you give, the weight of the motor is included and this brings the matter down to the point of what proportion of the 4,600 pounds should be devoted to the motor. Automobile motors weigh very close to 25 pounds to the horsepower when they are built in the sizes ranging between 30 and 40 horsepower. A 40-horsepower motor, that is, one that will develop 40 horsepower on the brake, will weigh close to 1,000 pounds.

If you want a motor in the car that will take the passengers up any hill and in which you will not have to be continually dropping to a lower speed everytime that a slight grade is reached, the motor should be capable of developing 40 horsepower at least to carry comfortably the load of 4,600 pounds.

Where To Place the Gearset

Editor THE AUTOMOBILE:—A gearbox in unit with the motor enables the clutch to be inclosed, giving a very neat appearance: it is easily and therefore cheaply manufactured. Regarding simplicity, this depends upon the design of the unit, as some cars using unit power plants are readily accessible while others are anything but accessible. Regarding flexibility this type of construction can be hung so as to be undisturbed or thrown out of line.

The amidship position is very good for heavier and higher-powered cars when used without a subframe. However, the manufacturing expense is greater, and the extra universal joints, while no doubt in many cases trouble-proof, require lubrication from time to time. This construction insures a good distribution of the weight on the frame.

The rear axle location is one that requires much more thought and study than the average designer who has attempted this design has given it. The drawback is not the additional unsprung weight, but the absolute necessity of swinging the propeller tube and gearshift levers from the same common point. If this is not followed out, one of the most simple laws of mathematics is not taken into consideration and undue, and to say the least, unnecessary, wear is imposed upon the transmission gears. The fact that practically all [illegible] gearboxes, as well as [illegible] gearboxes, have [illegible] time and to add gear [illegible] gearshift lever [illegible] or less trouble. [illegible] gearbox and the gear [illegible] connections means that [illegible] later in these linkages [illegible] lever is in its proper place [illegible] words, the ten foregoing [illegible] having a fair show as they are [illegible] partly in mesh.

It is granted that, by placing a [illegible] differential and rear axle gearbox, these [illegible] ably be overcome; but why not [illegible] construction and thus do away with [illegible] tear on the gearbox gears, one of the [illegible] modern motor cars?

East Orange, N. J. [illegible]

Motor Will Not Throttle Down

Editor THE AUTOMOBILE:—What is the [illegible] It will not throttle down but will run very [illegible] If I leave the motor running slowly it will [illegible] cylinders and the other two will be dead. [illegible] beautiful condition and I get a vigorous spark [illegible] at 50 revolutions a minute.

New York City. [illegible]

—You have probably by this time tried giving [illegible] a little more gas. A richer mixture is really what [illegible] at low speeds but the cause of the trouble is [illegible] much air gets into the cylinder through bad valve [illegible] leaky intake manifold. Note the joints and gaskets [illegible] pipe as shown in Fig. 1. The valve guide also may [illegible] of suspicion. The probable cause of the entire trouble [illegible] you will find to be in that the valves need grinding

Needs Larger Gasoline Spray Nozzle

Editor THE AUTOMOBILE:—In regard to Mr. Webb's trouble as printed May 15, I have had and am still having the identical experience with a car equipped with a Zenith carbureter. My car (Gregoire 18 horsepower) was built in 1910 and the carbureter was probably built for 1910 gasoline. I have had my cylinders rebuilt as you suggested to Mr. Webb, and did not in any way improve matters. It is my opinion that both of these machines (his and mine), are not getting enough gasoline and that enlarging the spray nozzle in the carbureter will help. If Mr. Webb wishes to know the results of my experience I will be glad to let him know.

As to Mr. De Luke's trouble, if he had a 30 by 4 tire instead

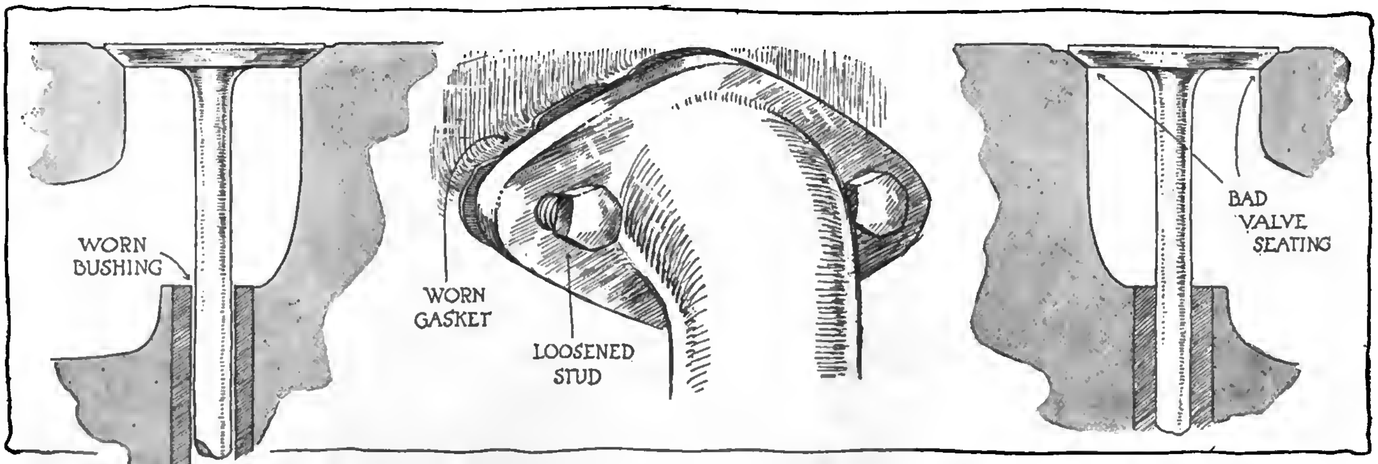


Fig. 1—Four causes of air leak are: worn bushing, worn intake gasket, loose stud and pitted valves

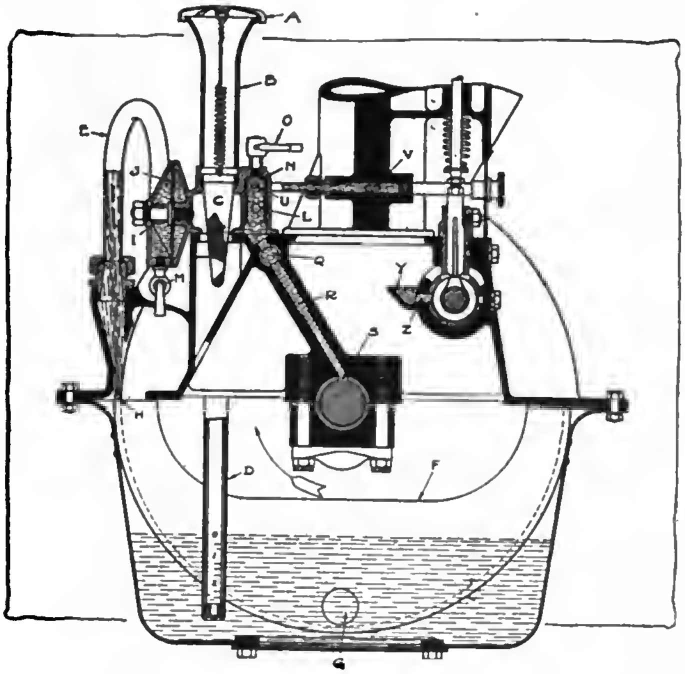

Fig. 2—Transverse section through the Hupmobile 32 crankcase

of a 30 by 3.5 he would have had an awful job getting it on and a worse one getting it off, as a 30 by 4 tire is smaller on its inside diameter than a 30 by 3.5.

New York, N. Y. GEORGE OPPENHEIMER.

Interested in Cyclecar Development

Editor THE AUTOMOBILE:—I am interested in the cyclecar which is attaining such prominence abroad and cannot see any reason why there is not a big field for such a type of vehicle in this country without infringing on the present field. From what I have been able to learn about the cyclecar it is a rational vehicle, and anything that is rational is sure to prove a winner if consistently pushed. With the increasing price of gasoline I see no reason why these economical little vehicles should not come into prominence in this country.

In your last issue I noted the consumption of gasoline in the recent Catskill tour over the 65 miles of road from New York City to Newburgh and having been over this road I know of the steep winding climbs up Crow's Nest Mountain, but am still convinced that our cars today use motors that are too large and also that many of our cars are too heavy.

I am quoting herewith some figures on cyclecar economy

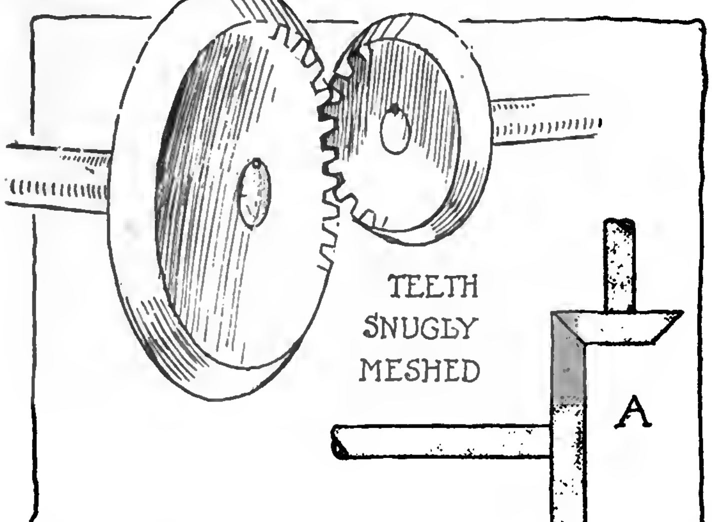

Fig. 3—Differential pinion should not project out of or into bevel gear

which I noticed in a recent issue of *The Cyclecar*. This was a road test with steep hills. The winning cyclecar averaged 82.1 miles per gallon. Its weight with passengers was 819 pounds. Other cyclecars averaged 69.67, 62.59, 56.54, etc., miles per gallon.

These figures speak real economy. With gasoline at 20 cents per gallon and 1 gallon doing for 80 miles, there is a cost of but .25 cent per mile for fuel. This is the type of vehicle that thousands of would-be car owners would like to have. It is a light car, one easy on tires and very cheap on fuel. It is not necessary that such a car be exceptionally cheap at first cost, rather that it be cheap to operate. There are hundreds who can afford to buy vehicles, but who object to the high cost of maintenance. It seems to me that the cyclecar offers an excellent solution to this problem.

Albany, N. Y. LIGHT CAR.

Correspondent's Error Corrected

Editor THE AUTOMOBILE:—The writer noticed in THE AUTOMOBILE for March 20 an account of the new automobile tax laws of Indiana, and note that you have an incorrect report of same. The correct rates are copied from the Acts of the 1913 Indiana Sixty-eighth Session, Section Six, as follows: "The following fees shall be paid to the secretary of state upon the registration or re-registration for each calendar year. For each motor bicycle so registered, the sum of $2; for each motor vehicle of 25 horsepower or less, the sum of $5; for each motor vehicle of 40 horsepower or less and more tban 25 horsepower, the sum of $8; for each motor vehicle of 50 horsepower or less and more than 40 horsepower, the sum of $15; for each motor vehicle of more than 50 horsepower, the sum of $20, and for each and every electrically propelled motor vehicle so registered, the sum of $3. Provided that for motor vehicles which are used or to be used solely for commercial purposes, the fee for such registration shall be $5 annually."

I note that you did not state in your previous account the method to be employed in calculating the horsepower in conjunction with this law.

Section 2 states that "in application for license party must state name of manufacturer and factory number of vehicle, the character and amount of motive power stated in figures of horsepower in accordance with the rating established by the association of licensed automobile manufacturers." This the writer concludes to be the old A. L. A. M. formula which is

$$\frac{D^2N}{2.5} = \text{H.P.}$$

There has been much discussion among Indiana automobile owners regarding this law, as most of them had read your accounts in THE AUTOMOBILE. Consequently, I think you owe it to your Indiana readers to make the correction.

Romney, Ind. CLYDE L. BURGHARDT.

—This was an error by the correspondent which THE AUTOMOBILE is glad to have corrected as per Mr. Burghardt's letter.

Lubricating System of the Hup 32

Editor THE AUTOMOBILE:—Would you call the Hupmobile 32 lubricating system a splash system? Does a splash system use more oil than a pressure-splash or pressure system?

San Diego, Cal. MARK JUNGK.

—The Hupmobile 32 lubricating system is a combination gravity and force-feed type. Although the camshafts and valve mechanism are lubricated by the spray thrown off by the connecting-rods the bearing surface of the motor are lubricated in the main by the gravity system.

The oil is contained in the lower part of the crankcase of the motor which has a capacity of 3 gallons. This is one point in which it resembles the splash lubricating systems and in this type of lubrication the reservoir is generally found in the crankcase. In the Hup car the flywheel acts as the oil pump. Referring to Figs. 2 and 5, the oil is lifted up by the spaces

G in the flywheel and carried up to the passage H. At this point the oil is thrown with considerable force, due to centrifugal action, through the inverted U-shaped passage E. From this point the oil runs to the chamber I. Within this chamber there is an oil strainer J, through which all the oil is compelled to pass, taking out the dirt and grit which can be drained off occasionally by opening the petcock M.

The oil now passes to the body of the oil regulator I, which governs the amount of feed to the bearings. It is automatic in its action and is controlled by an interconnection with the throttle. The oil is distributed from the regulator to the crankshaft and cylinders by means of a valve N, which is operated by a lever O connected to the accelerator through the mechanism P. When the throttle is opened about one-quarter the entire way, the valve N in the regulator starts to open and allows the incoming oil at L to flow down the channel R to the main bearings S. The oil channel is an integral part of the crankcase being drilled through the webs of this casting. From the main bearings the oil passes through the holes in the crankshaft and thence to the lower connecting-rod bearings and by centrifugal force the excess is sprayed all over the interior of the motor. This oil spray which pervades the entire crankcase is sufficient to oil the pistons at low or ordinary motor speeds. At higher motor speeds or when climbing hills and the throttle is more than half open the valves begin to open to the oil tubes at U and allow the oil to flow to the cylinders through the openings which register with the opening in the ends of the wristpins when the piston is at the bottom of its stroke. Though the openings in the wristpin the oil finds its way in sufficient quantities to thoroughly lubricate the piston.

Splash and force-feed systems use about the same amount of oil. It takes a definite amount of oil to properly lubricate a motor and a correctly designed system will first use that given amount.

Difference in Power with Muffler

Editor THE AUTOMOBILE:—Kindly let me know if there is any increase in power by reason of running cars using gasoline as fuel with the muffler cut out. I claim that there is no appreciable increase if the car is provided with a large size exhaust pipe entering muffler. In cities the practice is, I believe, generally prohibited. Is there any make of car that is not provided with a cut out?

Warrensburg, Mo. A. L. KENYON.

—The chart, Fig. 4, shows the small difference in power with and without a muffler cut out at a recent test made on a Packard motor. It will be noted that this was so small that it could not be noted in running the car.

There are several makes of cars that are not furnished with cut outs. The Peerless car is a noteworthy example of this as the makers have not been putting cut outs on the car since the car was first put on the market.

Incorrect Meshing Causes Growl

Editor THE AUTOMOBILE:—Will you kindly give me some information on how to silence a noisy differential gear? My car is a Maxwell runabout AA model, 1910. The gears make a growl. There is plenty of heavy grease in the housing. In fact, it was recently taken out and examined. What depthing should the drive pinion have? Is this noise caused by pinions not being meshed properly, either too deep or shallow? Please give me instructions on how to obtain the proper depthing for pinions, also other probable causes to be looked into for this trouble.

Clinton, N. C. F. R.

—Gears which are meshed improperly have a tendency to set up a rubbing action when meshed too deeply and thus give rise to a humming sound. When the meshing of the gears is not deep enough a rattling sound is produced rather than the continuous hum of the too deeply meshed gear. The correct meshing of the gears cannot be better described than that the teeth

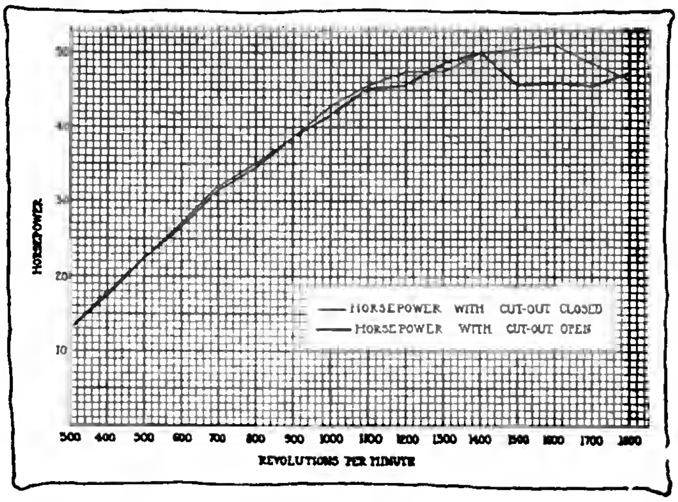

Fig. 4—Chart showing difference of horsepower with and without muffler

should fit together snugly without play. This is distinguished from gears in which the teeth are pressed tightly against one another. It will be remembered that where the 45-degree pinion meshes with the differential wheel there is a considerable wedging action possible. This may be understood from Fig. 3 which shows how these two gears mesh. When the pinion is moved back too far it is capable of exerting a tremendous wedge action which, combined with the ordinary driving pressure, is sufficient to cause a rapid grinding away of the teeth. Grinding actions are always combined with noise because the nature of the operation sets up a strong vibratory action in the metal.

When the gears are meshed too deeply a tap or knock will result at every change of load. Under a constant load there is a good possibility of the gears being pressed firmly together by the load and the knocking or rattling effect will not be so apt to be produced.

It must be remembered that the main cause of noisy gears is not so apt to be a faulty meshing of the gears but will rather be due to the fact that the gears themselves have worn. When the gears are worn, a temporary silencing effect will be secured by bringing them deeper into mesh, but the next wear will be quicker since the hardest part of the gears will have been worn away by that time. In bringing differential gears closer into mesh with the driving pinion the two gears should be worked together. That is, the pinion should be moved back slightly while the differential gearwheel should, at the same time, be moved over toward the pinion. This makes a sort of double adjustment which is really necessary to compensate for the different conditions which will result from changing only one of the gears.

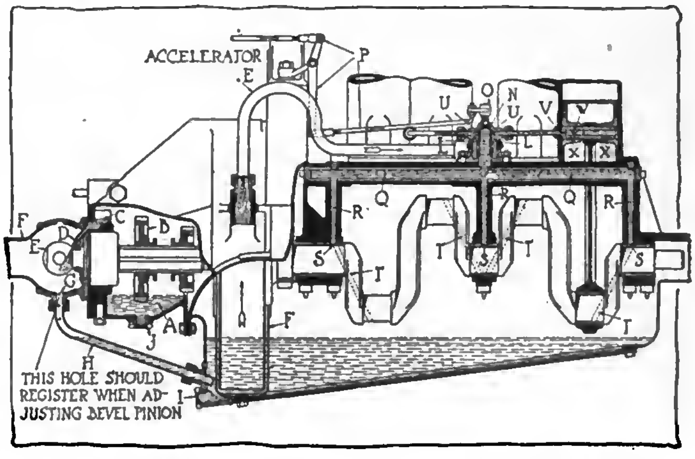

Fig. 5—Longitudinal section of the Hupmobile crankcase showing oiling

Howard Six Has Double Exhaust Line

Cylinders Cast in Threes with Separate Manifold and Muffler for Each Block—Design To Minimize Back Pressure and To Insure Silence

ONE of the new cars which was announced at the time of the Chicago Show was the Howard Six, manufactured by the Howard Motor Car Co., Connersville, Ind. This company is utilizing the old Lexington plant and started the work of assembling chassis in March. The plant has a capacity of 1,000 cars a year.

The new car is distinguished by minor refinements rather than by any radical tendencies in design. It is an assembled car and one of the aims of the designers, H. P. Tuttle and J. C. Moore, was to standardize all parts as far as possible. Some of the novel features are the use of a double muffler, double flexible exhaust pipe, and the bracket for extra tires bolted to the frame as shown in Fig. 2. The carrying of the wiring, gearshift slot arrangement and other similar details form practically the only departures from conventional practice as may be seen in the accompanying illustrations. The Electro starting and lighting system is used. The six-cylinder Continental motor of 4.125 and 5.25-inch bore and stroke develops 45 brake horsepower at 900 revolutions per minute and 60 brake horsepower at 1,500 revolutions per minute. The cylinders are cast in threes, the valves being inclosed by cover plates. Views of the motor are given in Figs. 3 and 4. The cover plates are shown in Fig. 3, which also shows the high mounting of the carbureter for accessibility and the exhaust manifold, the flexible tubes of which may be seen in Fig. 1. The idea in using the double exhaust system is to minimize a back pressure from the muffler and also to insure silent running. Three exhaust valves open into each exhaust line so that any one valve in either line if closed for 45 degrees crankshaft travel before the next valve in the same line opens. Four-point suspension is used for the motor and gearbox unit. The big truss support used at the front of the motor is shown in Figs. 3 and 4. The unit power plant is also supported by a subframe. An interesting feature of the design is that the motor is secured directly to the frame, thus obviating the necessity of a dustpan.

As may be seen in the illustration, Fig. 1, left drive and center control have been adopted by the designers, the steering column passing under the hood, while the gearshift is located directly on the gearbox.

Fig. 1—View of Howard six chassis, looking forward. Note flexible double exhaust pipes and junction box carrying the wiring beyond the dash. The box on the left running board contains the control switch and batteries for the Electro lighting and ignition system

Lubrication is of the splash system with constant level, driven by a plunger pump, with pockets for all bearings. The oil is fed up around the valve push rods, with an overflow back into the crankcase. Two oil fillers are used, one situated on the timing-gear case and the other at the back of the crankcase. Two universal joints are used between the gearbox and the differential.

Cooling is effected by means of a fan and centrifugal pump. The fan is adjustably mounted on top of the timing-gear case. An English and Mersick radiator of large capacity are used.

The method of carrying the wiring is distinctive, all wires passing through a junction box in front of the dash.

The Electro lighting and ignition system is employed. This system drives and is driven through the pump shaft and pump gear by means of a silent chain pulley belted to a pulley on the crankshaft by a Conventry chain. The control switch and battery for the starter are carried inclosed on the left running board. The battery used comprises twelve 24-volt, 20-ampere Willard cells.

Adjustable Individual Clutch Brake

An adjustable individual brake is used on the clutch to facilitate shifting of the gears. The adjustment is tightened in order to bring the clutch to a quick stop.

A Warner-Toledo gearbox is used, furnishing three speeds forward and reverse.

Drive is by shaft and bevel gear, final drive being through the springs and the torsion rod which is shown in Figs. 1 and 2.

The rear axle is of the standard Timken type having continuous press steel housing. The carrier comprises a complete power unit with gears, bearings and differential integral. Gears are forged heat-treated and ground. All moving parts are mounted on adjustable rolling bearings. The torque rod pins are hardened and ground and swivel in hardened and ground bushings with an adjustment for end thrust. The driving shaft is of nickel chrome steel with driving dogs formed integral and all moving parts are thoroughly protected from dust.

Brakes are of the external contracting and internal expanding type, 17 inches in diameter, the drums being of heavy pressed steel and all operating parts being provided with anti-rattling devices.

The tires are 36 by 4.5 inches all around and Firestone quick-demounable rims are regular equipment.

The Warner type of steering column and gear is employed. This embodies the worm and full gear construction, the latter being mounted below the worm in the usual way. Ball thrust bearings are fitted above and below the worm. It is adjustable in every way. The worm gear is integral with its shaft which is eccentrically mounted in a sleeve so that wear may be easily taken up.

The car is built in five-passenger touring form only, at the present time.

Although the designers have adhered to usual practice in the major details there are several little refinements which are well worthy of mention as indicative of unusual forethought and consideration for the comfort of the driver. Some of these are as follows:

A feature especially worthy of notice is the big tire bracket shown in Fig. 2.

This is bolted to the frame. It will carry either one or two tires and is designed to sustain a weight of 1,000 pounds. It is adjustable so that when arranged for carrying one tire there is no visible indication of a support for a second. No straps are required for securing the tires to the bracket.

An interesting departure is incorporated in the gearshift gate. Most gates have some mechanical stop arrangement to keep the driver from inadvertently throwing the lever into the reverse position while changing gear. In the Howard car a little psychological study evolved the idea that the driver will unconsciously pull the lever toward the reverse slot when he desires to reverse and that he will not exert this pull in simply changing from one forward gear to another. Consequently the Howard gate contains no stop but there is a slight curve in the gate itself which throws the gearshift lever across the H of the slot into second speed, reverse requiring the side pull to prevent the lever from crossing the slot.

The accelerator is of an unusual type, being globular in form, so that it may be operated from any angle. It is also made in such a way that it fits under the instep of the ordinary shoe, so that all the driver has to do to actuate the accelerator or to release it is to move his foot slightly backward or forward. This design permits of so great a variety of positions on the part of the driver that it should be a welcome feature, as the ordinary accelerator pedal permits of but one or two positions of the foot, which consequently becomes very tiring.

Novel Design of the Gasoline Tank

The 18-gallon gasoline tank is located under the front seat and pressure is maintained by an automatic positive pump driven by the camshaft. The novel feature of the gasoline tank is that it is shaped with an inclined bottom in order to assure fuel pressure at the carbureter when the car is tilted on an uneven road surface. There is a gauge on the footboard which shows that the gasoline is apparently all out at a point when there is still capacity for 40 miles.

The front lamps are controlled by a switch situated at the bottom of the steering column. The wiring of these lamps is interesting, the wires being carried up into the inside of the lamp brackets, thus protecting them and at the same time concealing them. The rear lamp is wired in a somewhat similar manner, the wire passing up through the frame to the lamp mounted on the tire bracket as shown in Fig. 2.

The spark lever on the steering column segment is fulcrumed in such a way that, although the lever is operated in the ordinary way to vary the timing of the spark, pressing it down blows the electric horn which is mounted at the left of the motor inside the hood with the bell projecting through the side of the hood. In mounting the horn in this manner it is no longer an excrescence but at the same time its efficiency as a warning signal is not diminished.

Fig. 2—Rear of the Howard chassis, showing the method of carrying the tire bracket. The spring suspension may also be seen, as well as the manner of covering the bolts on the rear hub caps

A feature of the horn mounting is that there is a fuse for each line permitting of testing out the wiring for any short circuit without removing the body.

The unsightly bolts on the rear wheel hubs are concealed by a metal cover put on inside the hub cap. The springs on the brake band levers are continued up in front.

Hassocks are used instead of a foot rest in the tonneau and are fastened to straps so that they can be pulled backward or forward according to the desire of the passenger.

Springs are of the conventional type, semi-elliptic being used in front and three-quarter-elliptic at the rear. Grease cups are fitted on all spring shackles and bolts. In designing the car special attention was paid to making the springs accessible for external lubrication.

Tools are carried in compartments in the cowl of the dash. There is also a small light fitted in the dash. The Troy rain vision windshield used is made a part of the cowl and requires no braces. Pump, jack, and inner tubes are carried in a compartment under the back of the front seat.

Regular equipment includes Stewart speedometer and grade indicator, mohair top and Jiffy curtains as well as the usual complement of tools and similar minor details.

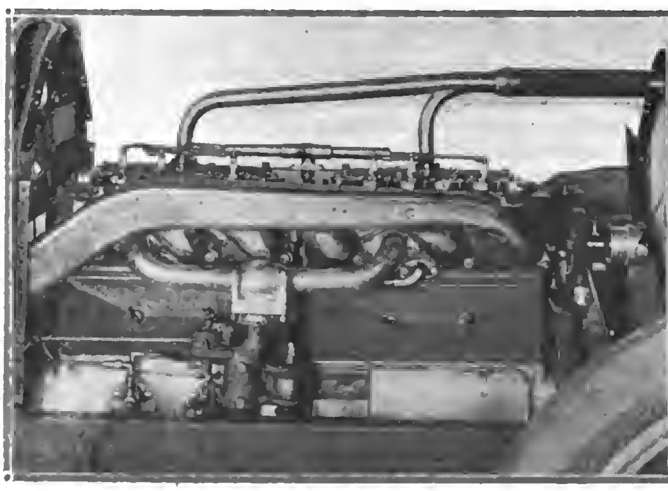

Fig. 3—Right side of the Howard six motor, showing high mounting of carbureter, neat method of carrying wires over the top of the motor and novel form of exhaust manifold

Sectional and working views of the new Shimpf starting motor and compressor

Unit Pumps and Starts

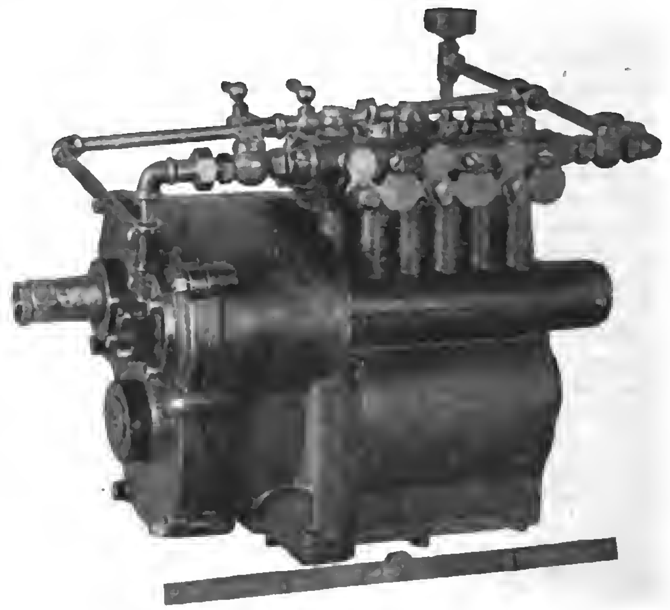
Can Crank the Motor or Pump the Tires As Owner Desires by Making One Simple Adjustment

THE SHIMPF starting motor and compressor, designed and built by Walter H. Shimpf, 1931 Broadway, New York City, as indicated by its title, is a motor and compressor combined in one unit, a device which under certain adjustment will act as a motor and under different adjustment will act as a compressor for compressing air, which may thereafter be utilized for various purposes, such as cleaning the car, operating brakes, blowing signals, pumping tires, etc., including the operation of the device as a motor.

When used in connection with an automobile, it is directly connected by a suitable means with some moving part of the engine, and through a system of gearing and automatic clutches, will either drive the engine for the purpose of starting it or be driven by the engine for the purpose of compressing air to a predetermined pressure into a receiving tank, thereafter remaining idle while the engine is in operation until the pressure is reduced.

The point of connection between the combined starting motor and compressor and the engine is, of course, immaterial as long as such connection insures the proper driving effect from the motor and compressor to the engine, and from the engine to the motor and compressor. The combined motor and compressor is what might well be termed a single-acting motor and and a multiple compressor, inasmuch as the various pistons receive an impulse of movement from the compressed air, exhaust at the end of the stroke, and discharge the contents of the cylinders during the return stroke without working against the compressed air; and when acting as a compressor, compress as individual pistons.

The opening of a valve on the dashboard automatically shifts the camshaft so as to bring into contact with the cams one or more of the push-rods, opening the valve to whichever cylinder



Exterior view of the Shimpf air-compressor motor

is at that time in position to receive the air under pressure; this in turn drives the piston and crankshaft, making an independent air motor which, through the two-to-one gear between the crankshaft and the jackshaft of the motor and a two-to-one gear between the jackshaft and the engine, revolves the crankshaft of the automobile engine, rotating the same until combustion takes up these duties. As soon as the automobile motor has started the closing of the dash valve allows the camshaft to return to a position where the cams do not actuate the push-rods, this operation making the valves automatic and the device a compressor. This device is so designed that by the shifting of the camshaft the various pistons will act directly as compressors or as driving pistons utilizing the same valves and depending upon whether the valves are actuated by the camshaft or actuated automatically.

With the two-to-one gear reduction between the jackshaft of the motor and the engine, when the engine is running, the jackshaft would revolve twice as fast as the engine shaft; to overcome this increased speed so that the crankshaft of the compressor will revolve at the same speed as the crankshaft of the engine, a counter reduction of two to one is placed between the jackshaft and the crankshaft of the compressor. The gearing of the starting motor and compressor is controlled automatically by roller clutches.

The present device is a three-cylinder, 1.625-inch bore by 2.125-inch stroke with crankpins at 120 degrees. The cylinder, crankcase and gearcase are block castings, occupying a space 13 by 10.75 by 8 inches.

The lubrication is by splash, the crankcase and gearcase acting as an oil reservoir. A pneumatically controlled dental clutch between the crankshaft and the two-to-one counter reduction controls the action as a compressor, allowing the compressor to operate until a pressure of 200 pounds is attained, and at that point automatically disconnecting so that the crankshaft, piston, etc., are idle. With this feature a very small amount of time and only a minimum power are required for its operation.

Observed and Calculated Critical Speeds—Prof. Dunkerly has demonstrated by experiment the existence of critical speeds in shafts and found that for shafts freely supported at the ends the observed critical speeds agreed very closely with those obtained by calculation.

Dr. Stodola in his experiments upon shafts has proved the existence of critical speeds of the second and third order and found that the ratio between the first and second and third speeds agreed closely with the calculated values.

To quote Dr. Stodola, "To prevent fracture of the shaft its greatest amplitude of vibration was limited to about .394 inch radius by rings about the shaft. The very first experiment proved the existence of higher critical velocities. The shaft vibrating originally at about .04 inch showed with an increasing velocity an unstable running; at about the critical value it bent and began to rub hard against the rings. Hardly had the critical value been exceeded before the shaft straightened out and no initial vibration could be observed."

It appears that as a general rule the running speed of automobile shafts is well below the critical value. It is, however, possible in some instances that at the high speeds used under service conditions, the vibrations due to the inequalities of the road surface may have a value so close to the natural frequency of the shaft under these conditions, as to become dangerous.

Claims 60.5 Efficiency

Combination Two-Cycle and Turbine Motor Said to Make Big Cut in Heat Losses

A COMBINATION two-cycle and turbine motor is the latest offer to the trade and public. The motor, which is shown in the illustration at the foot of this page has a double jacket around the cylinder. The inner jacket is for the cooling air while the outer jacket is for the incoming charge. Air is compressed in a cylinder above the combustion chamber and passes through the cooling jacket.

The lower part of the motor looks very much the same as an ordinary two-port two-cycle motor. The intake port is uncovered by the piston in its travel and the charge which is released from the passage around the cylinder enters the combustion space. The compression stroke takes place and the charge is then fired, exhausting at the bottom of the stroke into a passage leading to the flywheel casing which contains the turbine wheel.

The designers of this motor claim a marked gain in thermal efficiency resulting from their method of cooling and by utilizing the exhaust. It is claimed that the cooling losses instead of amounting to 33 per cent. as is now the case with the gasoline motor, will be cut down to one-half that and the exhaust loss which has been estimated at 44 per cent. in the average engine will be cut down to 22 per cent. The designers state that a large proportion of this loss will be transferred to the useful work of the motor and the resulting gain in thermal efficiency will amount to 38.5 per cent. According to this the thermal efficiency would amount to something like 60.5 per cent. This startling figure is claimed by the makers, the American Sem-Turbine Co., St. Louis, Mo.

A two-cylinder stationary engine of the type described above and illustrated herewith has been built and is now on exhibition at the headquarters of the company in St. Louis.

From a study of the drawings a motor of this design would appear to be 30 per cent. higher than an ordinary type. This is due to the placing of the air compressor on top of the cylinder. The air compressor is an integral part of the cylinder and in reality forms a supplementary reciprocating air pump.

Recent Incorporations in the Automobile Field

AUTOMOBILES AND PARTS

Brooklyn, N. Y.—Barber Anto Service Co.; capital, $10,000; to deal and hire automobiles. Incorporators; William Barber, A. S. Barber, M. F. Barber.

Cincinnati, O.—Allen Breed Tractor Co.; capital, $5,000; to manufacture tractor engines. Incorporators: Allen Breed, L. J. Dolle, H. V. Reedy.

Cincinnati, O.—Queen City Motor Delivery Co.; capital, $30,000; to deal in automobiles, transporting and delivering merchandise and passengers. Incorporators: Louis Hehman, H. G. Hehman.

Cleveland, O.—Haupt Co.; capital, $5,000; to deal in antomobiles. Incorporators: W. D. Haupt, H. A. Couse, R. G. Curren, Mary McManus, Alfred Clum.

Detroit, Mich.—Grant Motor Co.; capital, $100,000; to manufacture a small type of car of tha cyclecar class. Incorporators: G. D. Grant, C. A. Grant, David Shaw, G. F. Salsman, J. M. Howe.

Detroit, Mich.—Wahl Motor Co.; capital, $85,000; to manufacture automobiles. Incorporators: G. G. Wahl, A. M. Dodge, Michael Matchwill, W. J. Heckish, E. E. Havens, T. M. Lemon.

Jacksonville, Fla.—White Sales Co.; capital, $100,000; to deal in automobiles. Incorporators: J. R. Collins, P. D. Cassidy, N. A. Collins.

Lansing, Mich.—Carter-Car Sales Co.; capital, $4,000; to deal in automobiles. Incorporators: E. H. Jenks, Charles Schmidt.

Little Rock, Ark.—Arkansas Automobile Exchange; capital, $5,000; to deal in antomobiles. Incorporators: Sam Yout, Estell Yout, S. J. Fechbeck.

Louisville, Ky.—Crown Motor Car Co.; capital, $500,000; to manufacture antomobiles. Incorporators: V. F. Lambert, N. V. Lambert, O. H. Lambert.

New York City—Universal Equipment Co.; capital, $50,000; to deal in engines. Incorporators: George Gray, T. W. Hatfield, I. B. Owens.

Pittsburgh, Pa.—Pittsburgh Haynes Antomobile Co.; capital, $10,000; to deal in automobiles. Incorporators: H. S. Morrow, E. K. Morrow, Alva Hughson.

Rochester, Ind.—Rochester-Mais Commercial Car Co.; capital, $25,000; to manufacture motor trucks. Incorporators: J. A. Mais, A. C. Davisson, E. A. Miller, J. M. Ott, R. P. True.

St. Louis, Mo.—H. G. Borbein & Co.; capital, $10,000; to deal in automobiles. Incorporators: H. G. Borbein, L. W. Becker, L. B. Borbein.

Syracuse, N. Y.—Service Boat and Engine Co.; capital, $10,000; to deal in motors. Incorporators: W. J. Eastman, L. J. Rolfsen, C. L. Ripley.

Trenton, N. J.—Hall & Taylor Co.; capital, $25,000; to deal in antomobiles. Incorporators: W. H. Taylor, H. A. Hall, Harold Hall.

Wilmington, Del.—Electromobile Co.; capital, $100,000; to manufactura an electric automobila. Incorporators: H. E. Latter, W. J. Maloney, O. J. Reichard.

Wilmington, Del.—Victor Motor Car Co.; capital, $100,000; to deal in automobiles.

Buffalo, N. Y.—Buffalo Automobile Spring Co.; capital, $10,000; to manufacture springs for nutomobiles. Incorporators: Earl Plants, W. E. Slater, H. E. Spangler.

Chicago, Ill.—Ferns Motor Livery; capital, $50,000; automobile livery. Incorporators: M. M. Franey, A. J. Coline, H. P. Mumms.

Cleveland, O.—Cleveland Antomobile Country Club; capital, $7,500; to carry on an automobile club. Incorporators: T. P. Cagwin, H. M. Adams, R. H. Lee, F. H. Caley, A. A. Atwater.

Detroit, Mich.—Chambray Carburetor Co.; capital, $50,000; to manufacture carburetors and other automobile accessories. Incorporators: J. H. Chambes, H. W. Mowbray, C. H. Bennett.

Flushing, N. Y.—Flushing Auto Moving Express and Taxi Cab Co.; capital, $1,000; automobile express business. Incorporators: Nicholas Gilroy, James Whitcher, Robert Mills.

Indianapolis, Ind.—Oakes Pressed Steel Co.; to manufacture steel stampings. Incorporators: W. H. Oakes, W. D. Oakes, C. G. Swenson.

Milwaukee, Wis.—Porto Metal House & Garage Co.; capital, $5,000; to manufacture and market portable steel structures for automobile storage or outing purposes. Incorporators: J. E. Tracy, P. G. Meyer, J. P. Weber.

New York City—Specialty Auto Parts Co.; capital, $5,000; to deal in automobile accessories. Incorporators: G. I. Aronow, A. M. Newburg, A. H. Peyser.

New York City—Square Motor Horn Co.; capital, $5,000; to deal in antomobile horns. Incorporators: S. Socgnamillio, Frank Buckman, Alexander Karlin.

Philadelphia, Pa.—New Idea Tire Co.; capital, $500,000; to manufacture automobile tires. Incorporators: F. R. Hansell, G. H. B. Martin, S. C. Seymour.

San Antonio, Tex.—International Automobile School of San Antonio; capital, $4,000; to instruct pupils in repairing automobiles. Incorporators: T. P. Price, J. A. Kerr, Gus Leroy.

Scranton, Pa.—Economy Automobile and Lackawanna Vulcanising Co.; capital, $10,000; to vulcanise automobile tires.

Syracuse, N. Y.—Syracuse Auto Radiator Co.; capital, $50,000; to manufacture the Kaman radiators. Incorporators: Max Kaman, Minnie Kaman, Thomas Vickers.

Toledo, O.—Toledo Merchants Delivery Co.; capital, $50,000; to do a general deliver business and storage business. Incorporators: J. H. Pheatt, G. M. Reswick, H. W. Braser, L. F. Luscombe, J. E. Parsons, Jr.

Wilmington, Del.—E-Z Anto Tire Pump Co.; capital, $20,000; to manufacture an automobile tire pnmp. Incorporators: F. D. Buck, G. W. Dillman, B. M. Grawl.

Wilmington, Del.—Pneumatic Rim & Tire Co.; capital, $200,000; to deal in antomobile tires and accessories. Incorporator: Harry Davis.

GARAGES AND AGENCIES

Antigo, Wis.—Holland Flexible Auto Wheel Co.; capital, $10,000; to manufacture a flexibla wheel for automobiles and trucks, which obviates the need of pneumatic tires. Incorporators: J. L. Donahue, J. E. McKenna.

Baltimore, Mo.—Dreadnought Tire & Rubber Co.; capital, $1,000,000; to mannfacture antomobile tires. Incorporators: A. F. Gilbert, Wilmer Dunbar, W. E. Hill, C. P. Tiplett, W. B. Swindell, Sr., A. A. Adt, A. F. Gilbert, W. E. Hill, C. P. Triplett, B. H. Diggs, H. E. Whitelock, A. B. Whitelock, G. H. Rice.

Brooklyn, N. Y.—Atlantic Garage Co.; capital, $5,000; general garage business. Incorporators: J. M. Simon, Charles Steinbeck, Mary Steinbeck.

CHANGES OF NAME AND CAPITAL

Akron, O.—Diamond Rubber Co.; capital, decreased from $100,000 to $10,000.

Birmingham, Ala.—Robertson Tire & Auto Co.; capital increased from $20,000 to $50,000.

Fostoria, O.—Allen Motor Car Co.; capital increased to $500,000.

Indianapolis, Ind.—Cole Motor Co.; capital increased from $500,000 to $1,000,000.

New York City—Studebaker Vehicle Co.; capital decreased from $3,600,000 to $600,000.

HENRY S. CHAPIN, New York City, has invented a new type of rebound check which is distinguished by effectiveness, smoothness of action and light weight, in addition to the extraordinary simplicity and consequent low cost of manufacture. In short, the device shown in Figs. 11 to 13 consists of a flat bar or plate secured to the masterleaf of an elliptical spring, on the free side of the same, its length and rigidity being so proportioned as to afford a resistance to spring rebound. The end edge of the plate bearing against the spring is rounded.

As Fig. 11 shows, one of the simplest forms in which this spring check may be applied, consists in placing a plate shaped to contact with the central portion of the masterleaf in such a position that it is in touch with the concave side of it, when the spring is under normal load. If the car travels, the spring, of course, begins to vibrate, thereby tending to alter its shape continually from moment to moment. The plate P, being more rigid than the spring steel, does not follow the alterations of the shape of the spring, but its rounded edge is made to slightly slide along the spring surface, due to its curvature and by its changing point of contact helps considerably to counteract and annihilate vibration, first, of the masterleaf and through this of the other leaves.

In case of a shock, when the masterleaf of the spring tends to curve itself beyond normal, the plate comes into principal action. Thanks to its rigidity, it cuts—so to speak—each side of the spring in two parts; namely, that covered by the plate and the remaining portion. The rounded edge of P provides a fulcrum, almost stationary due to the rigidity of the material, around which the outer portion of the spring must turn. As the spring leverage is considerably shortened by moving the fulcrum from the end of the U-bolt to the edge of P—as is done by the use of the plate—the force acting at the end of the spring and which otherwise would result in a considerable deformation of the same is reduced very much and the deformation proportionately. In other words, the short leverage from the edge to the end of the spring masterleaf makes excessive deformation very difficult and frees the ordinarily sudden return to normal shape from the shocking nature otherwise accompanying it. One of the main reasons for the action of this spring check is the fact that the check-bar or plate P and masterleaf are always in contact at their common point of attachment as well as at the edge of the plate, so that a sudden jumping action on the part of the spring leaf is impossible. In addition, there is the devibrating effect of the plate.

Rushmore Electric Starter—S. W. Rushmore, of the Rushmore Dynamo Works, Plainfield, N. J., has designed a starter of the electric-motor type which is operated by the simple pressing of a button mounted in reach of the driver's hands. If this is done, a pinion of the armature is brought into engagement with a gear formed on the flywheel periphery.

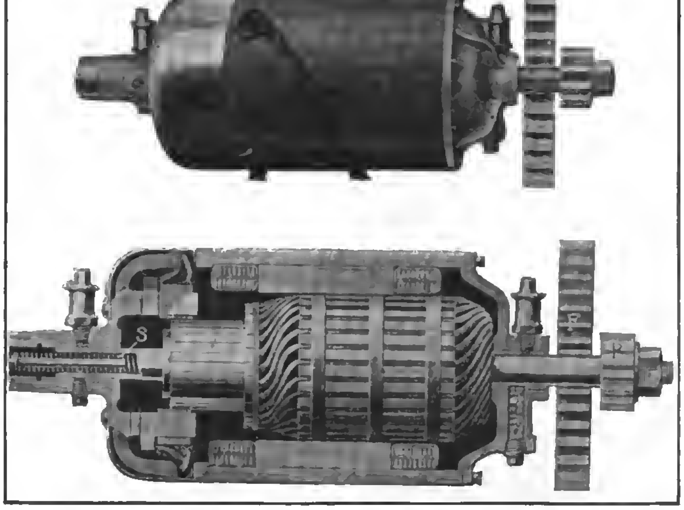
The starter which consists of the motor and pinion, weighs 47 pounds. It is constructed with a 6-volt series winding, both for the general use of this voltage in lighting systems and because a higher operating efficiency is claimed for it than if a higher voltage were used. One of the most interesting, and in fact, most ingenious features of the device is the device for engaging and disengaging starter gear and flywheel. It consists of a compression spring S contained in the hollow armature shaft, which presses the latter and the armature out of its central or working position, so that pinion P and the gear F on the flywheel remain out of engagement. When the circuit is closed, the field is magnetized and by this action is made to draw into the working position the armature, on the principle of the solenoid. Thereby P and F are brought into engagement and the flywheel is turned over by the torque of the electric motor. As soon as the engine picks up above the speed of the starter, the latter is relieved of its load, the current drops and almost becomes nil, thereby permitting the spring to press the armature out of the operation position and to disengage the gears P and F.

Perfectite Waterproof Compound—The Price Fire & Water-Proofing Co., Poughkeepsie, N. Y., has begun to market a waterproofing compound which comes in a semi-solid form, being inclosed in cans and which may be made ready for application by thinning with gasoline, linseed oil or any other drying oil. It is furnished in 1, 2 and 5-pound cans, as well as in kegs of 25 and 100 pounds. Two pounds of Perfectite should be dissolved in 1 gallon of liquid and such a mixture is sufficient for waterproofing 100 square feet of canvas, top material, or the like.

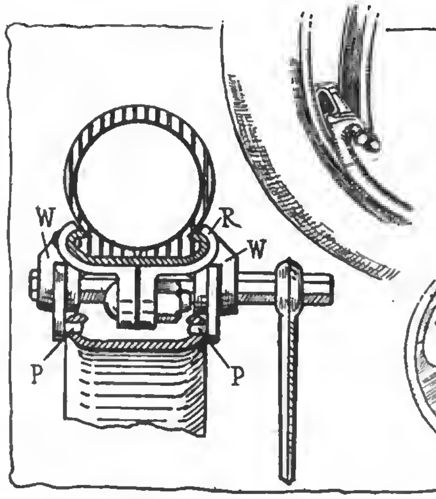
Funk Demountable Rim—Richard W. Funk, 1876 Broadway, New York City, is the maker of the demountable rim illustrated in Figs. 3 and 4. The rim proper is a split ring, the ends of which are connected by a pin-link mechanism, as in Fig. 4. One pin serves as a fulcrum, around which the other may be moved by applying a wrench to the hexagonal head formed on the pin, so that the two rim ends may be brought into alignment and contact. When this is the case, the rim, formed as at R, Fig. 3, forms a secure basis for the casing and the inner tube contained in it.

Rust-No Graphite—Asch & Co., 1777 Broadway, New York City, handle graphite stick shown in Fig. 16. It consists of graphite and a binder, being used to prevent rusting on of tires.

Edelmann Watch-Type Tire Gauge—E. Edelmann & Co., Chicago, have brought out a tire gauge, Fig. 5, in the shape of a watch which is fitted with a ring, so as to be adaptable for carrying on a chain. The size of the gauge is that of a small Ingersoll watch, and the appearance also resembles this, being contained in a nickel casing. The air which acts on the indicator mechanism enters through the stem portion of the casing, which portion is so designed as to fit any Schrader valve. The device works on the principle of the steam gauge; the indication remains and is released by pressing an extension of the indicator hand through the frame.



Figs. 1-2—Rushmore electric engine starter



Figs. 3-4—Funk rim.

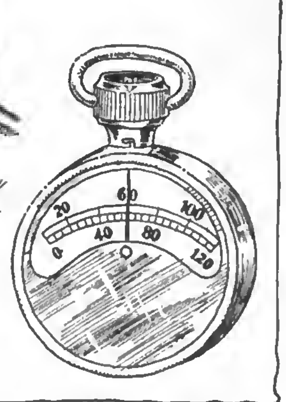


Fig. 5—Edelmann tire gauge

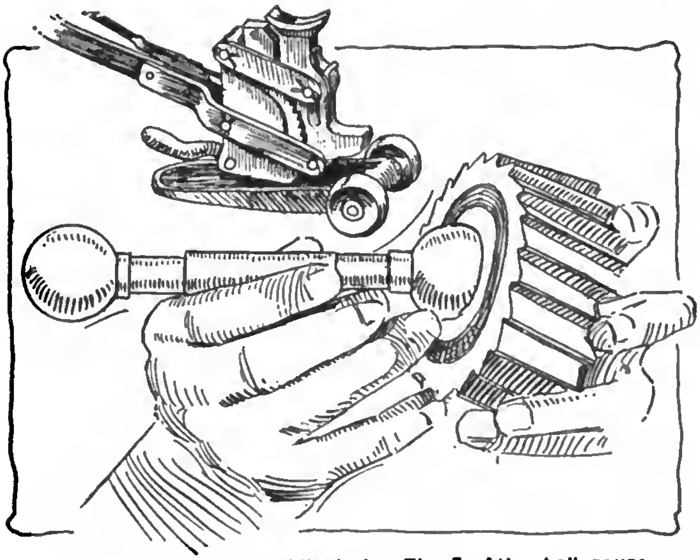

Fig. 6—Excel automobile jack. Fig. 7—Atlas ball gauge

The Excel Auto Jack, Fig. 6, designed for use in garages and tire agencies, is mounted on a wheeled base and provided with a long hand lever for quick and easy jacking. The housing is of crucible cast steel and all teeth are machine cut. The weight is 35 pounds and the height range from 9 inches lowered to 25 inches raised. The change from up to down movement is effected by a small thumb lever in a convenient position on the operating handle. These jacks are the product of the Excel Jack Mfg. Co., Fenway, Boston, Mass.

The Detroit Automobile Fire Extinguisher Co. has brought out the extinguisher shown in Fig. 9, which is furnished in either nickel or black enamel to match the trimming of the car.

It is so constructed that the operator can quickly detach the connecting tube from the end brackets by grasping same next to the spring clip. One quick pull releases the tube and it is thus open ready for action and can be thrown directly on the flame.

This extinguisher is made with two types of mountings, so that it can be screwed to the tonneau floor and used as a foot rail fixture or attached to the dash. In the latter case the brackets are shorter. The dash equipment is made in two sizes, that for pleasure cars being 12 inches in length and 2 inches in diameter, while the truck type is a heavier tube of steel measuring 20 inches by 2 inches. The foot-rail equip- is 12 inches by 2 inches.

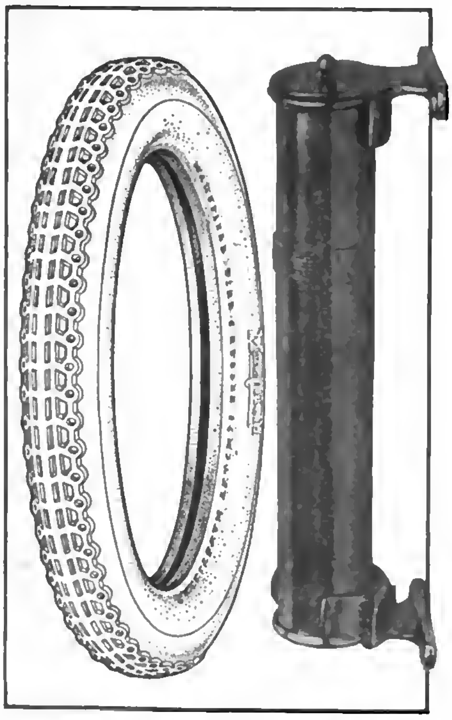

Fig. 8—Mansfield tread. Fig. 9—Detroit extinguisher

Stanley Hinges—The automobile hinges of the Stanley Works, New Britain, shown in Fig. 10 give evidence of accuracy in manufacture that will prevent rattling when in use. They are supplied in wrought steel 1.5-, 1.75- and 2-inch sizes. The lengths range from 2 to 5 inches and the makers punch and countersink the screw holes according to the specifications of the purchaser. The makers are also prepared to execute orders for hinges of any special size or shape.

Fig. 10—Stanley hinges for automobile doors

A new non-skid tread has been brought out by the Mansfield Tire & Rubber Co., Mansfield, O. It has five parallel cables which are connected by cross-bars in M manner. These bars are space .75 inch to provide hollows which grip the road surface. It is claimed by the maker that the uneven surface of the tread not only gives good traction but that the spaces formed between the cross bars prevent side skidding.

The illustration shows that the principle used in this casing is not new, but well tried out before; but a new and pleasing shape has been found, which undoubtedly is accompanied by a number of distinct advantages.

The Atlas Ball Gauge consists of a hardened and accurately ground steel sphere welded to a handle. Its purpose is the accurate measurement of internal diameters. In use the spherical shape facilitates the insertion of the gauge and also renders the operation of taking a measurement much simpler as the handle can be held at any angle to the part being measured. These gauges are guaranteed to .0001 inch and for the gauging of the shaft hole in gear wheels, etc., they are made in a double type as shown, in which one ball is called the "go" end and the other the "no go" end. The machined part can be passed when the hole is such that the smaller ball, the "go" end, can be entered but the larger or "no go" end cannot. These gauges are made by the Atlas Ball Co., Philadelphia, Pa.

Miller Grease Gun—The manufacturer of the Miller grease gun, Fig. 14, has brought out the new grease scoop, Fig. 15, so as to make charging of the gun easy. The gun here shown is made of brass throughout, consisting of four parts: The cylinder and cap fastened to it, the leather-packed piston reciprocable in it by turning the screw-cut rod formed with a pentagonal handle, the removable cat at the opposite end and the spout screwing into hole in its center. The leather washer fitting around the piston makes a tight joint with the inside of the gun cylinder and the removable cap fits the latter tightly, so that all grease put into the gun is positively discharged by way of the spout if the handle is turned. The scoop is stamped from a single strip of steel and is slightly bent along its longitudinal center line so that it easily picks up the lubricant. The other end of the scoop is cut, as shown in the illustration, so as to form a handle. This scoop is furnished gratis with the grease gun. Asch & Co., New York City, are distributors for this article.

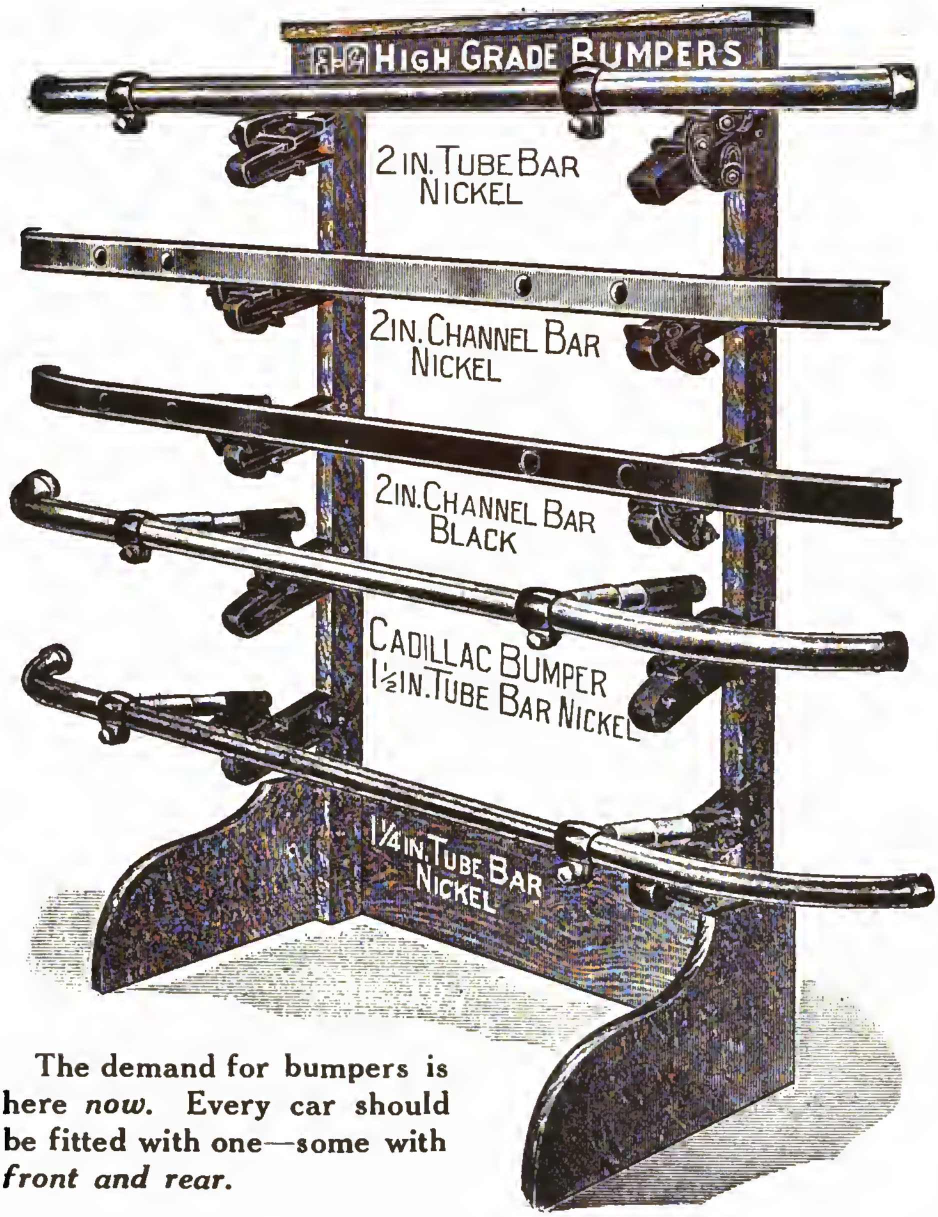
This Display Stand Will Sell Bumpers For You



The demand for bumpers is here *now.* Every car should be fitted with one—some with *front and rear.*

This compact bumper stand displays five full size models of E. G. HOOKBOLT Bumpers—in nickel, black and brass—for nearly all makes of cars. The stubs to which the bumpers on the stand are attached are patterned after automobile spring hangers in order to demonstrate that E. G. Bumpers may be applied to the frame without drilling.

To obtain one of these stands FREE, it is only necessary to purchase five bumpers as shown in the cut, at trade prices.

	List.		List.
1¼ in. Round Bar Bumper, Black	$6.75	2 in. Round or Channel Bar, Black	$10.00
1¼ in. Round Bar Bumper, Brass	7.50	2 in. Round or Channel Bar, Brass	12.50
1¼ in. Round Bar Bumper, Nickel	9.00	2 in. Round or Channel Bar, Nickel	15.00

Cadillac and Rear End Bumpers

Same prices as above, according to style and finish of bar.

Bumpers are shipped assembled on the stand—ready for the display room—no bother or work.

Emil Grossman Company Manufacturer **250 W. 54th St., N. Y.**

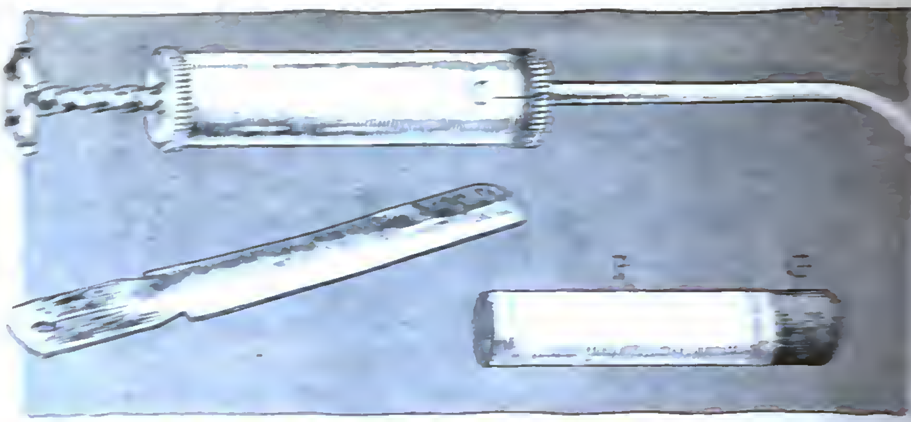


Fig. 14—Miller grease gun. Fig. 15—Miller grease scoop. Fig. 16—[illegible]

Motor Car Equipment Horn.—The Motor Car Equipment Co. of New York City has taken up the sale of a novel automobile signal which combines the clearness of the bulb-horn note with the ease of operation otherwise obtained only from electric or exhaust-operated signals. The new horn is shown in Fig. 17. It consists of two principal parts, namely, the bulb horn and the small air pump which impels the air used for producing the sound of the horn. As Fig. 17 shows, the pump is mounted so that the wheel attached to it does not touch the flywheel rim, but is brought into contact with it if the lever to which the Bowden wire is attached is drawn forward toward the small wheel's shaft. This is done by pressing upon a small lever shaped like a pedal and mounted on the rim of the steering wheel, as here illustrated. The Bowden wire proper is enclosed in a flexible tube which is so mounted that pressure upon the small lever does not move it, but the wire passing through it. The pump thus operated by the force of the flywheel contacting with the small wheel produces an intense current of air which is taken in at the opening of the pump casing fitted with a screen and discharged at the other opening of the casing in the direction of the tangent of the impeller blade periphery. The air current is led through a heavily-woven metal-covered tubing to the inside of the horn, where it is expanded into a bell-shaped space. From there it passes through the reed and the conical tube into the projector, whence it leaves the horn with great strength. The mounting of the pump is by means of bolts and nuts which fasten to the motor frame, while the horn proper is secured to the front of the dashboard or at any other suitable place.

Amper Lock Switch.—A lock switch which is controlled by a combination lock is being made by the Amper Electric Co., Lockport, N. Y. Figs. 18 to 21 illustrate the construction of this lock. A knob on the front of the casing controls three cylinders which have peripheral grooves to permit spring tumblers to drop into them if the knob is turned to the proper places. If this is done the spring tumblers arrest all three cylinders one after the other until certain slots formed in the cylinders are in alignment with the switch lever so that the latter may be turned moving the cylinders along with it. If the switch is then turned back to the off position a slight turn of the knob is sufficient to lock the device. On the back of the instrument connections are provided for the wire contact from battery and magneto to the spark-plugs.

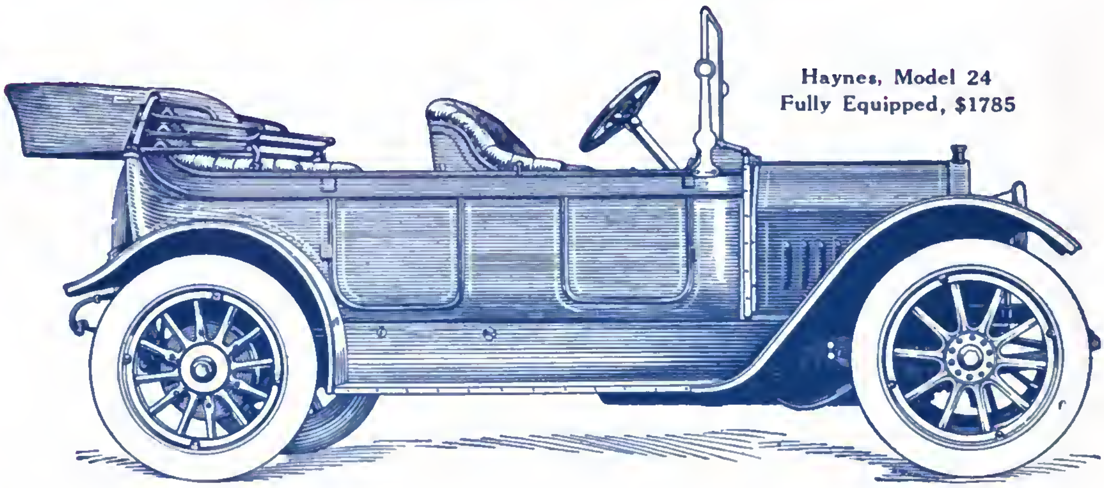
HYATT QUIET

Sincerity is Built Right into the

HAYNES

America's First Car



Haynes, Model 24
Fully Equipped, $1785

LOOKING at it from your view point, in choosing a line you will consider several things which are more important **to you** than the size of a manufacturer's factory, or how many **thousands** of cars he builds, or how many **talking points** he may have in **equipment**.

The Haynes factory (new plant built and completely equipped in 1911) has been called by authorities "one of the most efficient plants in the world." The Haynes output is large enough to earn minimum costs on parts and materials—not so large as to make Haynes cars **common.** Haynes equipment leaves **nothing** to be asked for.

But Haynes **Sincerity means more to you** and to your trade than these things mean.

Haynes sincerity is possible only in such an organization as this, where the original builder of the original Haynes of 1893 still is, and through all these years has been, at the head of the same organization; where the skilled machinists have **grown up** in the plant, inspired always by the Haynes spirit; where the same designing engineer has, for many years, worked out the logical development of the motor car; where every workman's wage is paid by the week and **not** by the piece; where for nearly a generation the business policy has been dictated by honesty of purpose and earnestness of effort.

No other car at a medium price can offer you such Sincerity. Those who own Haynes cars know the tangible money value of this sincerity. You, too, can find in it an assurance of dependable service, comfort, safety and economy.

Two Models

Model 24, four cylinder, 5-passenger touring - - - $1785
Model 23, Haynes "Six," 5-passenger touring - - - $2500

Regular equipment complete. All models electrically started and lighted by the Leece-Neville separate unit system. Left-side drive, center control. Generous advertising support for Haynes dealers.

The AUTOMOBILE

Goux, Peugeot, Wins $50,000 Race

World's Record Holder Covers Course at 75.92 Miles Per Hour—Race 14 Minutes Slower Than Last Year

INDIANAPOLIS, May 30.—Goux, Peugeot, France, are the three words on the lips of 96,000 automobile racing enthusiasts who gathered at the speedway in this city today to witness the 500-mile classic race for a purse of $50,000. Translated into motoring vernacular these mean that Jules Goux in his French Peugeot racing car vanquished the pick of America's speed pilots, defeated some of England's best known sons, laid the pride of Italy low, triumphed over the skill of Belgium's best and carried away all honors at today's great contest.

Starting in a field of twenty-seven, Goux piloted his special racing creation over the entire 500 miles at a speed of 75.94 miles per hour, between 2 and 3 miles per hour slower than the winning pace of a year ago. During the 200 circuits of the speedway he fought in turn with the picked drivers of the world, but finally won out with a margin of 13 minutes and 8 seconds over his nearest competitor and 1 hour and 21 minutes ahead of the tenth driver to finish and carry off a part of the $50,000 spoils.

Jules Goux, a youthful, slender Frenchman, had many contenders whom he fought with in turn on practically even terms until he had turned the 400-mile mark when he seemed to enjoy renewed life, shook off all other contenders and shot his fleet monster toward the 500-mile goal. His time was exactly 14 minutes slower than the pace set by Dawson in the winning National a year ago. Goux won three trophies, Remy Brassard, for leading at 200 miles, the Prest-O-Lite for leading at 300 miles and the Wheeler and Schebler for leading at 400 miles.

But if France was first and carried the coveted $20,000 to foreign shores, American brawn was well to the fore and captured second and third places for the Stars and Stripes, yielding fourth position to England, fifth to Belgium and the remaining five places to America.

Spencer Wishart in a Mercer was second, traveling 73.49 miles per hour, nosing out his fellow-American, Charles Merz in a Stutz by the narrow margin of 36 seconds.

The English Sunbeam piloted by Guyot, a Frenchman, was fourth at 70.92 miles per hour, and fifth position went to Pilette of Brussels driving a Mercedes-Knight sleeve-valve motor entered by E. C. Patterson, the Chicago sportsman. The Mercedes-Knight, one of the smallest motors in the race,

Upper—The winning Peugeot stopping at the pits. Note cooling of tires by pouring water on them. Circle—Jules Goux, winner of the 500-mile race and his mechanician, Begin just after the contest.

250 cubic inches displacement in a 450-cubic inch class, averaged 68.14 miles per hour and made one of the most consistent performances of the day.

Five other cars finished, making ten in all to complete the five centuries. Their order was: Howard Wilcox in the Grey Fox, a special car built by C. P. Fox, an Indiana sportsman, speed 67.65 miles per hour; Ralph Mulford in a Mercedes, poppet-valve type, 66.94 miles per hour; Louis Disbrow, Case, 66.79 miles per hour; Willie Haupt, Mason, 63.48 miles per hour; and George Clark in a special car, the Tulsa, built by Oklahoma sportsmen, speed 62.98 miles per hour.

Only Eleven Cars Finished

Only one other car was running at the finish of the ten who divided the money among them, it being Bob Burman's Keeton which had led for many miles during the early hours of the contest but lost hours due to puncturing the gasoline tank, having to change carbureters and his carbureter catching fire.

Of the twenty-seven starters, sixteen fell by the wayside for one cause or another. The race, though slower, was a more enjoyable, and fascinating one than that of a year ago, the slower pace not being recognized by the contestants because of the changing positions of the leaders until the 400-mile mark was reached, after which the Peugeot was never headed off and started opening a gap of 3 minutes between it and Gil Anderson's Stutz which disputed every mile of the race until eliminated at 460 miles when running in second place by a broken camshaft. From 3 minutes the gap grew to 4 at 440 miles, then to 6 at 460 miles, then to 12 at 480 miles, and finally ended in a lead of 13 when the checkered flag was reached.

Today's race was one of thrills, yet remarkably free from accidents, only one marring the sport, that being the overturning of Jack Tower's Mason at 125 miles, Tower suffering a broken leg and his mechanic some fractured ribs. Scarcely had the starter's flag been laid aside when the crowd was stirred by the struggle of the American drivers with the pick of France, Goux and Zuccarelli in their Peugeots. Bragg, who had the inside position in the front line of starters, took the advantage and led the field for the first lap; Evans put No. 5 Mason into the lead for the second lap; he held it in the third but Goux came into the front on the fourth, held it by 200 yards in the fifth, increased it to 400 in the sixth, added a little more in the seventh and gained some more in the eighth. With eight laps, 20 miles, covered, it looked as if the much-touted Goux was going to make a runaway of the day. But the hopes of his admirers were short lived for Burman, who was late reaching the starting line due to replacing a broken steering knuckle, and who got away at the tail end of the list, was getting his graceful Keeton under way and at 40 miles was leading the Frenchman by 2 minutes, Goux having blown a tire 20 minutes after the start and requiring 78 seconds to change his wheels with tires.

Burman a Possible Winner

Burman had his Keeton running perfectly, hitting over 100 miles per hour on the straightaway and coasting the turns. It looked as if his chances were good. At 60 miles he had 3 minutes' lead on the Frenchman with three other cars between him and Goux. At 80 miles he still led with over 3 minutes leeway, at 100 miles he retained a good margin; at 120 miles he still led, but fortune failed him, his carbureter caught fire, he lost nearly an hour and Goux took the lead at 140 miles with Anderson's Stutz, Mulford's Mercedes and Guyot's Sunbeam all bunched 3 minutes behind him. Once more it seemed Goux's chance to pull away if his tires would only hold up. They did and he led for another 100 miles until pushed out of position at 240 miles by the Anderson Stutz and Mulford in the Mercedes. At 260 miles the Frenchman got the premier position back with a margin of less than a minute. Mulford and Anderson hung on with the desperation of demons. At 300 miles Goux had opened a gap of scarcely 2 minutes on Anderson but at 320 Anderson was back in front with 23 seconds on the Peugeot.

But fortune changed and positions went up and down. Goux took the lead at 340 miles and held it to the end. For 120 miles Anderson's Stutz hung onto him with determination that warmed the heart and fired the enthusiasm of every American who watched the gladiators, and until a broken part robbed him of a well-earned second place when but 30 miles from the finish.

Anderson and Goux in a Duel

Anderson and Goux were battling in a class by themselves 8 to 10 minutes ahead of the remainder of the field. It was a noble fight, with odds favoring the special Peugeot, the prize-winner for the tricolor a year ago. When Anderson coasted into the pits, lifted the hood of his motor, gave a few turns of the starting crank and then pushed his white racing machine back a pall of gloom fell over the countless thousands. America's best fighter had given away to a foreign foe and the public looked to new leaders for America. Hopes were placed on Wishart's Mercer and Merz's Stutz running scarcely a minute apart. But they were 12 minutes behind the flying Goux and with scarcely 20 miles to go there was little hope of victory. Goux counted on tire trouble, but with expert pit aid he scarcely lost a minute to a change, he saw the race was won, he slackened his pace and won easily.

With first position settled, the fierce duel between Wishart and Merz for second position and the $10,000 purse was taken up by the grandstands and bleachers. Although not in the limelight, these two had been waging equal warfare from the very start of the grind. They were generally 4 or 5 minutes back of the leaders until the 400-mile mark when they were 13 or 14 minutes back of the Frenchman.

From the drop of the flag to the finish it was a neck-and-neck battle between Wishart and Merz, with but 35 seconds separating them at the finish. First one had the advantage, then the other, with not a minute separating them for over 300 miles. Merz led his rival by 26 seconds at 100 miles; at 200 Wishart led by a minute and a half; at 300 miles Wishart had his greatest margin, nearly 6 minutes; at 400 miles Merz had reduced it to less than 2 minutes; at 420 miles Wishart led by 9 seconds; at 440 miles he was 58 seconds up; at 460 it was 51 seconds, at 480 but 29 seconds, and then 35 seconds apart. Merz's finish was spectacular in the extreme. Just as he got the green flag, meaning that he started his last lap, flames burst out under the bonnet at each side. Simultaneously the cry went up "He is on fire." All looked for him to stop, but, never slackening his pace, Merz sped for the finish. Up the back stretch the flames could be seen gaining headway. Everybody wondered if he could make it, wondered if the insulation on his wires would bring him to the tape or if second or third position would be snatched from him as was De Palma's lot a year ago. Every eye followed the white racer around the far turn, back of the bushes and then into the home stretch. The flames brightened but Merz held his pace and as he shot over the line with the mechanic vainly endeavoring to keep the flames under the hood he was given a cheer that rarely is accorded to a third-place car. The 35 seconds meant $5,000, the difference between second and third places.

Sunbeam Pleased I. A. E. Men

The Sunbeam, winning fourth place, gave all the visiting English engineers, the guests of the American Society of Automobile Engineers, a chance to wave their Union Jacks from a private stand erected for them close to the timers' pagoda. The running of this car was one of the consistent features of the race. Guyot put it into fourth place at 60 miles and held it in fourth, fifth, sixth or seventh position until 400 miles when he

Circle—The timers' pagoda, the Marmon which run in 1911, and the National, last year's winner

Lower—Bragg's Mercer, the Sunbeam, Liesow's Anel almost abreast at an early stage of the race moved into fourth and held it to the finish. The car, with its long bottle-shaped black body, moved with the utmost ease, its long wheelbase handicapping it slightly on the turns. Guyot never pushed it. He was playing the safe game from start to finish, being determined to end within the money, of which he eventually carried off $3,500. He changed but one tire from start to finish.

Mercedes-Knight Very Consistent

If the consistency of the Sunbeam was noteworthy that of the Mercedes-Knight was more so. It being the first Knight-type motor to be seen in a race of any nature in America its performance was watched with the utmost interest. It had a piston displacement of 250 cubic inches as compared with 450 of the Peugeots. Pillette, who sells the car in Belgium, started on a 75-mile an hour clip. He started in eighteenth position; at 100 miles he was tenth; at 200 miles he was ninth; at 300 he was seventh; at 400 miles seventh, and at the finish fifth. So consistent was his work that everybody felt from the start he would finish well up in the money. He finished 45 minutes after Goux. At 100 miles he was 4 minutes back of Goux; at 200 miles 16 minutes; at 300 miles he was 21 minutes back, and at 400 miles 29 minutes.

A contender all through the race and one who might have finished in second or third place had he not carelessly run out of gasoline on the backstretch and lost half an hour getting a supply from the grandstand, was Ralph Mulford in No. 29 Mercedes. Mulford made one of the greatest runs of the day in that he did not change a tire from start to finish and did not make a stop until the race was more than half over. He was a leading contender until the race was past the 400-mile mark when he dropped from third to seventh and was not able to regain his lost advantage. Mulford was in fourth place at 100 miles; at 200 miles he was third; at 240 miles he was second, being less than 2 minutes back of Anderson's Stutz leading at that time; at 300 miles he was fourth, and at 400 miles he was

third. Soon after came his downfall, by a shortage of gasoline. His tank held 40 gallons and was filled at the start. At 275 miles 20 gallons were added but he ran out at 440 miles. His falling from third place moved Wishart and Merz up and when later Anderson, who was running second, fell out Wishart and Merz were moved up to second and third positions. Mulford won $1,800; had he held his place he might have been second with $10,000. It was costly gasoline.

Today's race had more than its share of troubles with cars due to a general lack of preparedness. They had not been driven enough, the parts were not well enough worn in. As a result, bearing troubles were many. Of the sixteen to fall out, at least five had troubles traceable to burned-out bearings. The Shacht broke a crankshaft; Stutz No. 3 broke a camshaft; De Palma's No. 2 Mercer burned out a bearing; Zuccarelli in No. 15 Peugeot, a duplicate of the winner, burned out a motor bearing; Nikrent's Case lost a bearing, and the Anel withdrew because of loose connecting-rod bearings.

Next to bearing troubles came those due to faulty gasoline lines and poor support of gasoline tanks. Two of the Isotta cars went out with leaky gasoline tanks. These cars arrived at the speedway 3 days before the race started. They were fresh from the Italian factory, where their manufacture was delayed by a strike. The bodies with the gasoline tanks in them had been built specially at an outside factory. The rivets tore through the tank walls. Harry Grant and Truccò, the Italian diiver, both withdrew for this trouble. Burman in the Keeton had gasoline troubles and changed carbureters during the race, putting on a Rayfield in lap fifty-seven. Mulford had more or less gasoline trouble from the start of the race.

Peugeot's Pit Well Managed

A measure of the glory accruing to Goux and the Peugeot car should be awarded to the excellent management of the repair pit. The Peugeot team was fortunate in having as its manager John Aitken, of National fame, whose experience in racing as a

Pilette in the Mercedes-Knight

Guyot in the Sunbeam

Wilson in the Gray Fox

A snap shot of Jenkins in his Schacht, taken just before the great contest began

driver on the Speedway and in pit work helped him to make an efficient organization in the French quarters. He was assisted materially in his efforts by Charles Faroux, consulting engineer of the Peugeot factory.

It was a matter of question as to the effect wire wheels would have on tire wear and it was expected that this year's race would be of some value in determining just how the wire wheels would affect the life of the casings in the race. However, the results of the race are not such that any definite statement can be made either for or against wire wheels as tire savers. Of the ten cars which finished, three of them were equipped with wire wheels and all three were well up in the money. The winner, Goux, Wishart, who took second, and Pilette, who captured fourth money rode on wire wheels, the others using wood. The Sunbeam used the demountable type.

There were a few breaks of parts that were quite unlooked-for. Two of the Masons and the Henderson had troubles with slipping clutches. Tetzlaff's Isotta broke a driving chain on the home stretch. The driver and mechanic pushed the car into the pits only to be disqualified for pushing a car on the course. Bragg twisted off a pumpshaft on his Mercer at 325 miles. H. Endicott, driving the Nyberg, withdrew under 100 miles because of the reverse shaft in the gearbox seizing. Tower's Mason skidded and upset at 125 miles. Burman, with all his trouble, had the only car to be running at the finish of the race when ten cars had completed the course and taken all of the prizes. For consistent work he and his car deserve credit.

Haupt and his Mason as they looked before the race

The elimination of cars started early in the race. Six contestants dropped out before 100 miles were covered, these being Schacht, Grant's Isotta, DePalma's Mercer, Zuccarelli's Peugeot, Endicott's Nyberg and Trucco's Isotta.

Between 100 and 200 miles two more withdrew, Tower's Mason upsetting and Nikrent's Case withdrawing.

Between 200 and 300 miles only one fell out, Tetzlaff's Isotta.

Between 300 and 400 miles a Waterloo occurred, four withdrawing, namely, Henderson, Bragg's Mercer, the Anel and No. 5 Mason.

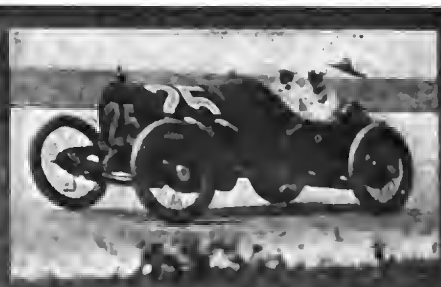
Between 400 and 500 miles only one fell by the wayside, it being the most pathetic of the race, No. 3 Stutz, driven by Gil Anderson, when it was in second position.

Wire wheels played a greater part in today's race than in any previous race in this country. Four different makes were in the race, Rudge-Whitworth, McCue, Frayer and Riley. The winning Peugeot used French-made Rudge-Whitworth detachables; No. 22 Mercer used American-made Rudge-Whitworths; and No. 23 Mercedes-Knight, finishing fifth, used English-made Rudge-Whitworths. No. 31 Case used McCue wire wheels; No. 35 Mason used Rudge-Whitworth, and No. 25 Tulsa used the McCue type of wheel. In recapitulation six of the ten cars to finish were equipped with wire wheels. Burman's Keeton, running at the finish, used McCue wire wheels and of the other contestants the three Isottas used the Riley wire wheels. It is impossible to state the accurate report of tires on wire and wool wheels with the object of gauging the relative merits of wood and wire wheels.

The tire story continues to be one of the engrossing ones of a big race. Owing to the cool weather preceding the race and the cool rains the bricks of the speedway were cooler than usual, but still much tire trouble developed. The right rear wheels suffered the most. Then came the left rear and lastly the right front. The left front tires gave little if any trouble. Goux, using Firestones, changed nine, five on the right rear, two on the left rear and two on the right front. The left front tire went through the race and was little worn at the finish. The big reason for wearing out the

Mulford in Mercedes

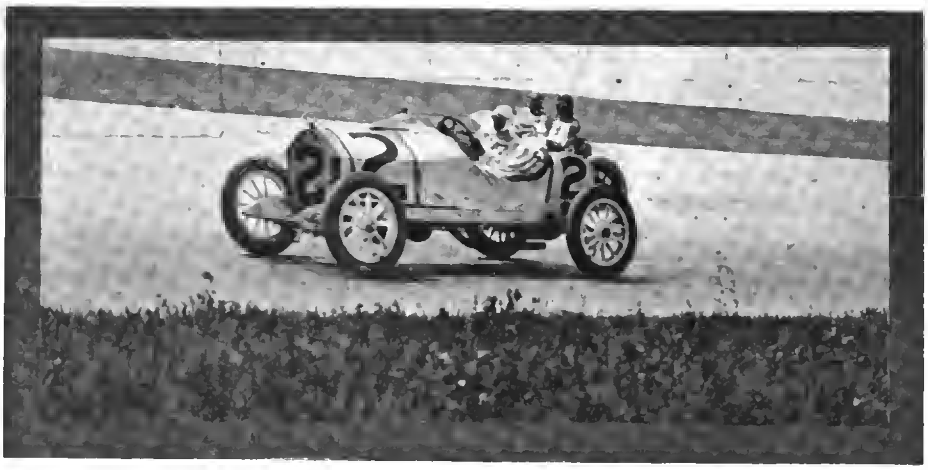
Case with Wisbrow driving



Clark driving Tulsa

right rear was because of getting off the smooth oiled center of the track. The rear wheels invariably slipped on the oily stretches and the dry, rough bricks tore the treads clean off several tires as the wheels spun around at great speed.

The most remarkable tire performance of the day were the Braender tires on Mulford's Mercedes. These are single-cured wrapped tread tires, made in Rutherford, N. J. By single cure is meant that the carcass and tread portion of the tire are all vulcanized together in one process, whereas in many tires there are two curing processes. Mulford's rear tires did not have a mark on them at the end of the 500 miles. There was one short cross-cut in the right front.



Stutz car rounding one of the banks, with Merz at wheel

Various other makes of tires were represented in the race. No. 22 Mercer, which won second place, used Michelins in front and Firestones in rear. No. 2 Stutz used Michelins all around. No. 9 Sunbeam used English Dunlops and changed but one during the entire race. No. 23 Mercedes-Knight used Michelins. No. 12 Fox used Michelins.

Practically all of the contestants used shock-absorbers in front and rear, some contenting themselves with one set of four but many others putting on two sets or eight in all. Hartfords were in general use with a few of other makes. Both Peugeots used eight Hartfords each. The Mercer used a set of four Hartfords and on the Stutz finishing third were two Hartfords in front and four in rear. The Sunbeam used four Hartfords in front and a hydraulic set in rear. The winning Peugeot used Bosch ignition and a Claudel carbureter.

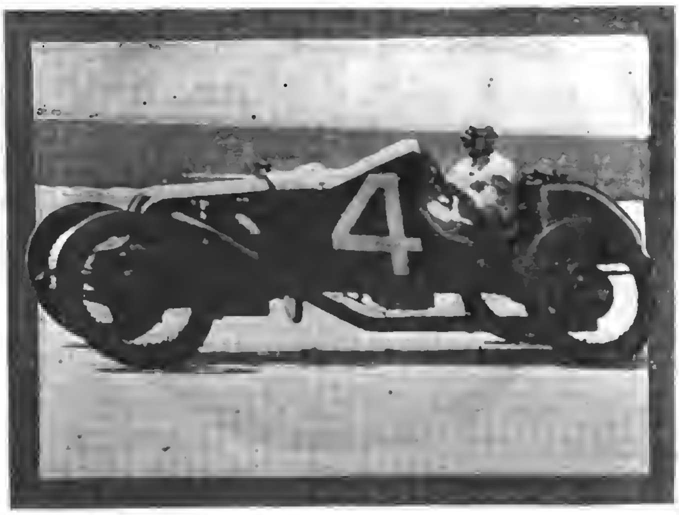
Some conception of the relative performances of the ten cars completing the race can be gained from the accompanying table, which gives their piston displacement and the speed in miles per hour that they averaged. The Peugeot was right up to limit and so was the Case.

These were the only cars to exceed the 400 cubic inch mark, the limit set by the rules being 450 cubic inches. No. 28 Mercer, and No. 23 Mercedes-Knight were the smallest capacity motors in the race, the Mercer 299 and the Mercedes-Knight 251. It would be possible to use a 400-cubic-inch limit next year and have practically as fast a race as that run this season.

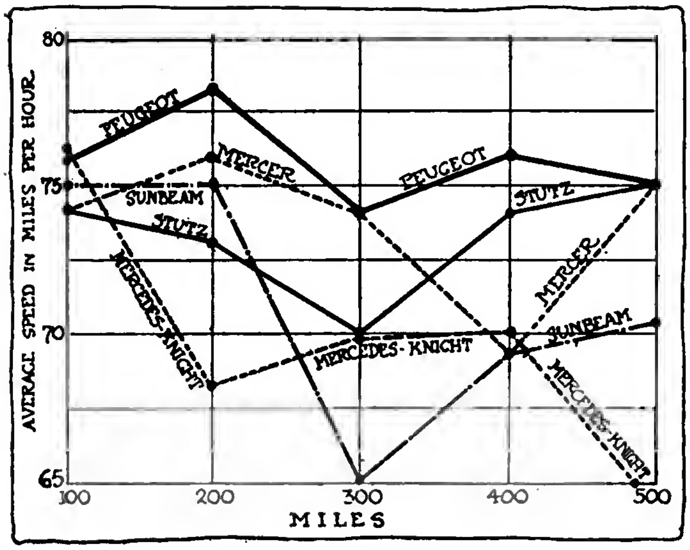
No.	Car	Piston Displacement	Speed
16,	Peugeot	448	75.92
22,	Mercer	299.7	73.49
2,	Stutz	399.97	73.38
9,	Sunbeam	380.8	70.92
23,	Mercedes-Knight	251.33	68.14
12,	Grey Fox	389	67.65
29,	Mercedes	440.8	66.95
31,	Case	449	63.08
35,	Mason	350.5	63.47
25,	Tulsa	340.1	62.99

To the Stutz team belongs the palm for quick and efficient pit work and to the men in the Stutz repair pit must be given a great measure of credit for the excellent showing made by Merz's car. In the matter of tire changes particularly did Stutz teamwork show up brilliantly. Tire changes were made in 30 seconds flat in some instances. The average time required to change the tires on the Stutz car was about 45 seconds and opportunity was taken during this time to renew the supplies of gasoline, oil and water.

This showing was due not only to the training of the pit men but also to the preparation and arrangements that had been provided for fast work. For instance, the jack used was a long wooden lever which lifted the wheels clear of the ground with one movement, an iron strap acting as a catch which was released by a kick and let the wheels which had already been started spinning down on the ground. Another feature of the preparation was the special funnels which could be dropped into the filler opening and the can of gasoline or oil up-ended into them without wabbling.



Burman's Keeton going over 100 miles an hour



Average speed of first five cars for each 100 miles

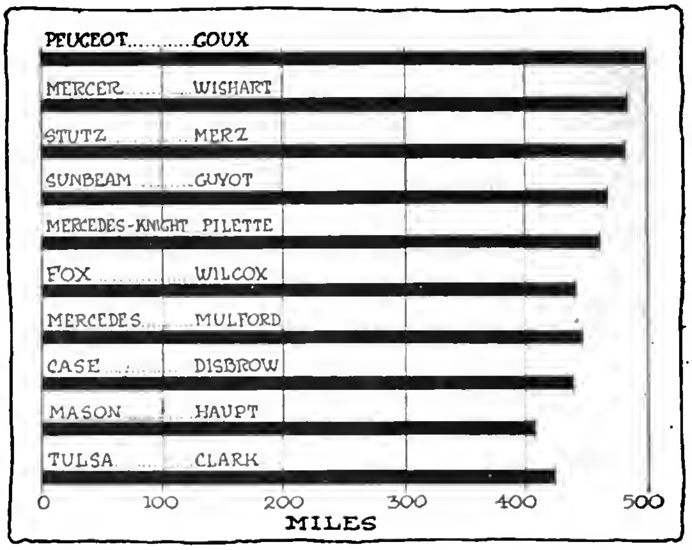


Chart showing positions of cars when Goux finished

Excellent generalship also was shown in the pit work of the Mercer team and although changes were not made as quickly as they were in the Stutz pits, yet stops for tire change and water, gasoline and oil required on an average only a minute and a quarter. The Mercer people had some difficulty with their jacks.

The Peugeot had a method of jacking that made for quick changes when two tires were to be replaced on either the rear or front axle. With this, a single jack of the long lever type was slipped under the differential housing and the entire rear axle lifted in one operation so that both the right and left tires could be changed simultaneously. The first stop of this car consisted of changing both rear tires and taking on gasoline and oil and the car was on the road again in 1 minute and 43 seconds. The Peugeot pit was ably managed by John Aitken, of National fame, assisted by Charles Faroux, consulting engineer of the Peugeot factory.

So far as mechanical troubles were concerned there were five cars that came through with clean scores and four of these were the ones that finished 1, 2, 3, 4 in the race. Goux' Peugeot, the Mercer 22, the Sunbeam and Clark's Tulsa did not have to stop at any time during the 500 miles for mechanical adjustments.

The only difficulty encountered by the Sunbeam was in the sticking of the hub-retaining nut when one wheel was to be replaced. The Mercedes-Knight came very close to finishing without difficulty but on its last few laps had a stuck float valve. Pilette diagnosed the trouble as due to the magneto and wasted considerable time before discovering that the fault was in the carbureter.

Troubles with the gasoline connections seemed to be the most frequent of any of the mechanical difficulties. The extreme vibration of the cars over the brick track at high speed played havoc with gasoline tanks and piping. In several instances flexible conduit had been employed to lead the gasoline from the tank to the carbureter but this conduit seemed to break with as great frequency as did the stiff copper tubing ordinarily employed. The pounding of the cars started the rivets in the gasoline tanks and caused leakage in several of them. In fact, this very difficulty was the cause of the withdrawal of two of the Isottas. A broken gasoline lead held up the Fox Special for 3 minutes during the early part of the race. The No. 10 Henderson, along with its other difficulties, had trouble with a break in the flexible conduit which led the gasoline from the tank to the carbureter. Burman's Keeton also developed a leak in the gasoline tank but a wad of chewing gum plugged up the hole successfully.

Tower's Mason, which turned over in lap 51. This was the only accident of the race. Tower suffered a broken leg and his mechanician some fractured ribs—C.N.E.

Next to difficulties with the gasoline line, slipping clutches were the most frequent cause of trouble. The Henderson was forced to spend nearly 20 minutes altogether in trying to adjust the clutch so that it would hold. Frequent applications of gasoline with a squirt gun were necessary and every few laps the treatment had to be repeated. Knipper, a large portion of the time before his withdrawal, was on his back under the car. The difficulty was relieved temporarily by driving in pieces of saw blade in the leather facing. Disbrow's Case also was bothered with a slipping clutch and lost 2 or 3 minutes on this account. The Mason No. 35 made eight stops after running about 200 miles, on account of clutch slipping. The saw blades wedged into the facing gave temporary relief but slipping continued in less aggravated form.

There was not as much trouble with valves and valve operating mechanism this year as during last year's race in spite of the fact that the motors were run at a higher speed than they were a year ago. Wilcox's Fox Special had to replace a rocker arm in one cylinder and had to change exhaust valves in two cylinders. No. 3 Stutz broke its camshaft which was the only mechanical difficulty it had. It put the car out. Liesaw's Anel had valve trouble and the exhaust valve had to be changed. It was found necessary to adjust the rocker arms on Trucco's Isotta and occasion was taken to try to remedy the leak which was beginning to show itself in the gasoline tank. The gasoline continued to leak.

Carbureter troubles affected several of the cars and this difficulty was the only one which Mulford encountered throughout the race, one stop being made necessary by a slight carbureter adjustment.

The $20,000 handshake of Goux and Begin, as the winners congratulated each other after the race—C.N.E.

Burman's chief difficulty was occasioned by carbureter troubles and he lost 21 minutes in changing carbureters shortly after noon. This, together with another 21-minute stop to fix the gasoline tank, lost him his position of leader which he had held up to that time and dropped him down to sixteenth place. Knipper's Henderson had to stop twice, losing in all 7 minutes on account of carbureter adjustments.

Difficulties with the steering gears occurred in only two instances, Disbrow's Case losing a nut off the tie-rod bolt and Burman having to replace a bushing on the steering gear. Burman's trouble was to be expected in as much as he had broken a steering gear twice in practice and his final adjustments on a front axle that had just been put in that morning made him late at the start of the race.

Lubrication troubles, while they were not the direct cause of any of the stops at the pits, were responsible for some of the difficulties already enumerated. The burned-out bearings on Nikrent's Case, Zuccarelli's Peugeot, DePalma's Mercer, and Harry Endicott's Schacht probably all can be laid to insufficient lubrication.

Eighty-eight new tires were worn out during the race. This means an outlay for tire equipment along of between $3,000 and $4,000. Tires were eaten up more rapidly this year than in previous speedway races because the day was warm and because there were oily spots on the track in which the tires spun and rasped the treads.

The ten cars which finished together with the two contenders, Anderson's Stutz and Burman's Keeton, used in all fifty-eight casings. These were divided among the four wheels as follows: right rear tires, twenty-nine; left rear tires, eleven; right front tires, twelve, and left front tires, three.

Disbrow's Case was nearly as fortunate as Mulford's Mercedes, making the complete run with only one tire change. The Tulsa, driven by Clark, wore out only two tires. The Sunbeam, fitted with demountable wooden wheels, replaced three tires. Goux's Peugeot wore out seven tires in all, three on the right rear, two on the left rear and two on the right front wheel. Wishart's Mercer made the run with five tire changes. Merz changed as many tires as did Goux, but lost only 5 minutes. The Peugeot lost 10 minutes. Pilette ground off the tread of one of his tires when running off an oily spot and stopped for a change. At the same time he took the precaution of replacing the other three tires, although they showed no signs of wear. Later in the day he stopped for another tire change, rather than run the risk of blowing out. The Fox Special ate up seven tires, losing less than 6.5 minutes. Haupt's Mason had to replace six tires, four of which were on the right rear wheel, losing 5 minutes. Anderson's Stutz held the record.

S. A. E. and I. A. E. Off on Lake Trip

Distinguished Visitors Royally Entertained at Indianapolis Race—Inspect Hoosier Capital's Automobile and Accessory Plants and Wonder at Magnitude of the Industry in Detroit

NEW YORK CITY, May 28—The British visitors, members of the Institution of Automobile Engineers, who arrived 2 days ago to be the guests of the S. A. E., left here at 9 a. m. today on a special train for Pittsburgh, after having been given a local reception by the members of the Metropolitan section.

After the first handshakes had been exchanged on Monday, when the guests arrived and were welcomed with an American beefsteak dinner, Tuesday was utilized to show them the greatness and splendor of New York. The Britishers were taken about the town in automobiles and during the morning they received a fair idea of what Gotham is and how it looks. This was followed by a luncheon tendered by the Automobile Club of America in its headquarters at Fifty-fourth street. In the evening, the monthly meeting of the S. A. E. was held in the ballroom of the McAlpin Hotel.

There, the subject of engine starters was taken up in an exhaustive manner. This subject had been chosen, because it was truly representative of American inventive and manufacturing spirit. R. B. Whitman read a paper on the starter situation and the influence of starters on design. After this representatives of starter manufacturers read papers illustrated by screen pictures and intended to be limited to 10 minutes each. Following were the starters described: Prof. W. C. Marshall's, Prest-O-Lite, Warner Gear Co.'s, Gray & Davis, Hartford, North East, Disco, Rushmore, Westinghouse, Ward Leonard, Bailey, U. S. Lighting & Heating companies and Entz.

H. Marmon, president S. A. E.

PITTSBURGH, PA., May 29—The visiting English engineers enjoyed a stay of one day here and then boarded their train en route for the races at Indianapolis tomorrow. During the forenoon a visit was made to the Carnegie steel works, while the afternoon was spent in a trip down the Monongahela and Alleghany rivers.

INDIANAPOLIS, IND., May 31—True Hoosier hospitality was shown the English engineers by the Indiana division of the S. A. E. during the 2 days spent in Indianapolis. The visitors

above shows the members of the English engineering society and the American S. A. E. grouped before the Ford plant

did not have an idle moment from the time they reached the city yesterday morning until they left at 9 o'clock tonight for Detroit. The 500-mile race at the speedway, of course, was the *pièce de résistance* of the visit, but the hospitality did not end there. That used up yesterday, while today was devoted to visits to the Wheeler and Schebler and Prest-O-Lite plants and a ride through the country adjacent to Indianapolis with a so-called luncheon at the Indianapolis Canoe Club, which in reality was a noon-day banquet, finishing with a visit to Broad Ripple where the visitors were treated to an old-fashioned clambake, which kept them busy until time to catch the train to Detroit.

The visitors were late in reaching the speedway yesterday, but as they marched into the paddock and took their seats in the special stand provided for them, which was located just north of the pits, they created quite a sensation. The hospitality of the speedway management was extended to them in the shape of refreshments and the men from across the big pond spent the rest of the day pulling for the Sunbeam and expressing their admiration of the big track and the system that prevailed in handling the race.

"It's a magnificent track and we from England are much surprised at your enterprise," said one of the visitors, H. Massac Buist. There's a vast difference, though, between it and Brooklands. At our speedway you cannot get the view of the race you can here. With us it is more in the nature of a road race, with the cars disappearing from view, while here one can watch them all the way around. I must say that I like this the better. Brooklands is faster—there is no doubt about that, but that's because of our high banking, where the cars can run to their limit. Here a car that has a powerful motor has the best chance because of its accelerative powers. On these turns, where you have to shut down, it is necessary to be able to make a quick pickup of the speed after coming out of the turn."

The admiration of the English for the 500-mile race was followed by the suggestion that possibly a similar race could be organized at Brooklands, although the Britons confessed that it would be impossible to get anything like the attendance Indianapolis had. It was suggested that possibly an international team race could be organized, with five cars representing each country. Some of the visitors promised to take up the matter upon their return.

T. B. Browne, president I. A. E.

It was 10 o'clock this morning when the Englishmen started on the last lap of their Indianapolis visit. Climbing into cars at the Claypool which were driven mostly by engineers from the Indianapolis factories, the first visit made was to the Wheeler & Schebler plant, where the process of carbureter manufacture proved an interesting study. Each of the party was presented with a rose by President Frank H. Wheeler, while every department of the big plant was thrown open for inspection.

Following this the visitors were whirled to the Prest-O-Lite plant at Speedway, the new horseless town. This plant, just opened, kept everyone going for more than an hour. The Britons, who rely mostly on acetylene lighting hy generators, marveled at the utility and simplicity of the Prest-O-Lite tank system, and absorbed every word of information given out by the company's employes. A demonstration of the new starter was made, which also enthused the visitors, who know comparatively little of self-starters.

Next a jump was made to the Indianapolis Canoe Club, also just opened, where the visitors had a chance to see what country club life was like. It was an oppressively hot day and the cool porches were most inviting. The luncheon tables were spread on one of the porches overlooking the river and a most elaborate meal was served, which was followed by several speeches. Howard Marmon, president of the Society of Automobile Engineers, presided as toastmaster and called on H. O. Smith, president of the Premier company, for the first remarks. In a most graceful speech which breathed the hospitality of America and the admiration of the Americans,

Henry Souther congratulating Basil H. Joy on George Houk's gift

for the English engineer, Mr. Smith extended a cordial welcome to the Middle West. Replying, President T. B. Browne of the I. A. E. spoke wittily, while C. A. Bookwalter, former mayor of Indianapolis, made the address of welcome on the part of the municipality, showing a familiarity with the motor industry that impressed his hearers.

Leaving the club at 4 o'clock the engineers next were treated to a 10-mile drive through the country adjacent to Indianapolis to Broad Ripple, the scene of the clambake. It was a novel experience, that clambake, and although the party had just got up from the table, still everyone was able to make inroads into the repast, which consisted of chicken, lobster, fish and clams.

Prominent in the entertining were several of the Indianapolis engineers—Wall of the National, Weidley of the Premier, Crawford of the Cole, Howard Marmon and George T. Briggs, of Wheeler and Schebler.

Busy Time in Detroit

DETROIT, MICH., June 2—The party of twenty-five English engineers, which has been augmented to the number of about 150 by the arrival of representatives of American concerns from all over the country, have been putting in a busy time since their arrival in this city.

Yesterday being Sunday was spent by the party in gaining a slight rest from their tiresome travel and rather arduous program. Motoring trips to various parts of the city were taken and an opportunity for general relaxation was given. Today a start was made at 9.30 a. m., for the Ford plant.

The party of 115 engineers and ladies spent the forenoon at the Ford plant getting an idea of what it means to manufacture 1,000 cars per day. The activity of the plant, the organization of the various departments and the methods of manufacture and assembly astounded and bewildered the Englishmen, many of whom were unable to comment on the production methods, other than giving vent to their amazement at the speed of production.

J. B. Dunlop, of tire fame, and T. Clarkson

Henry Ford personally piloted the party through the factory, having as his right-hand guest President Browne of the Institution of Automobile Engineers, and on his left J. B. Dunlop of Dublin, the inventor of the pneumatic tire. The procession first went to the final inspection department in the back yard of the plant where each chassis is given its road test amounting to scarcely 100 yards of driving necessary in order to get in line and pass between two inspectors who glance over the chassis, examine the production papers with it and pass it along to take its body. Today the chassis were passing one in every 20 seconds, or three a minute and 180 per hour. At this rate an 8-hour day should register 1440 chassis.

The method of shipping Ford cars in knock-down condition

George W. Houk and H. M. Swetland are Interested

in the freight cars was next seen. The chassis occupy one end of the car, the bodies and all other parts the opposite end. The wheels are taken off the chassis and they are placed at an angle of 45 degrees across the car. This permits of the closest packing possible.

The production sheet for today showed that by 8 this morning 100 cars had passed through; by 9 o'clock 200 had been manufactured; at 10 the records showed 317, and an hour later 437 had been checked through. The daily output ranges between 925 and 950 at present. A short time ago a record was made, 1,117 cars being turned out in a single day.

The English and American engineers alike were interested in the multiple methods of production which have characterized Ford manufacture since the inception of the present four-cylinder model. Interest at one minute centered in a multiple-drilling machine which makes forty-five holes at the same time. These holes are drilled in the cylinder casting. The drills work from four sides—namely, top, bottom, right and left. By stop-watch it took exactly 2 minutes from the time the workman picked the casting from the pile back of him until he put it into the jig, drilled the holes, took the casting out and laid it down on the pile at the other side of him. A few feet away other machines were behaving with equal human intelligence. The stop watch showed exactly 1 minute necessary to put castings into the drills, have the holes drilled and return the casting to its place.

What interested Basil H. Joy, secretary of the I. A. E., most was the method of piston manufacture, it being accomplished in about the same fashion that a lead pencil is sharpened by an automatic machine sharpener. The piston in the rough is mounted on a vertical spindle. Immediately it starts to revolve two cutters begin operations, one cutting the sides and the other the piston head, both being so timed that the operations are completed at practically the same second. Immediately they are done four other cutters begin, three cutting the grooves for the piston rings and the fourth the broad recess opposite the end of the wristpin. The beveled edge of the piston head is accomplished by another cutter. While the stop watch was not held on the operation, it was but a slight pause in the procession to watch the entire job.

The fact that Henry Ford employs workmen by the day and week and has no one at piece work astonished all of the visitors. They imagined that piece work was the only possible method to be employed in a factory employing 16,000 workmen. Their excursion through the plant soon convinced them that Ford accomplishes results in other ways, in a word, that he is a general of men and so arranges much of the work that the pieces undergoing work pass in procession through the hands of perhaps six or a dozen workmen so that if any one workman slackened the regular pace he would hold all of the others in the series back, the work would pile up around him, and the only conclusion would be that he was not competent for the job. Ford has proven that he is right, and that results can be obtained without piece work.

T. Clarkson, manufacturer of steam omnibuses for the city of London, was an interested observer and student of Ford production. Mr. Clarkson was a visitor to America for the Chicago Fair 20 years ago, when motoring was scarcely in its swaddling garments.

Group on steps of Ford plant—Mackie (hands in pockets), Norton (arms folded), Prestwick (arms behind back)

One of the pleasantest features of the day occurred just at the completion of the Ford visit when George W. Houk, controller of the Rudge-Whitworth wire wheel interests in America, presented a full-fledged touring car to Secretary Basil H. Joy of the visiting engineers. Mr. Houk has known Mr. Joy for years, having lived 14 years abroad. Henry Souther, ex-president of the S. A. E., made the presentation speech. The presentation was a spur-of-the-moment affair, Mr. Houk purchasing the car a few minutes before it was presented, and the car itself having been manufactured while the visitors were passing through the factory.

The entire afternoon was spent by the party in making the rounds of the factory of the Cadillac Motor Car Co. Here the visiting engineers were given an opportunity of seeing the American methods of manufacture which had been worked out in a plant which is working on an annual schedule of 15,000 cars.

Two of the visitors—C. H. Wheeler and R. H. Smith

The last 1913 car is scheduled to leave the factory of the Cadillac company at 5 p. m. of June 14. On that day the last of that model will have passed through the assembling plant and the entire manufacturing attention will be given over to the 1914 product. For the coming season 18,000 cars are scheduled, and material and accessories for that number of cars has been ordered.

Welcome from the Cadillac

On the arrival of the party at the Cadillac plant after luncheon at Ardussi's, the members were led to a reception room which but a few hours before had been a part of a busy machine shop. Seats were arranged in rows and the party seated themselves and listened to an address of welcome by H. M. Leland, president of the Cadillac company. Mr. Leland explained the manner in which the party was to be conducted through the various departments and assigned each group to a separate guide.

Following one of the parties through the works many expressions of interest were head from the English visitors. The elaborate system of gauging every piece of work by under and over-limit gauges provoked general comment. The large machines designed for special work were also greatly admired.

One of the representative parties going through the works started at one of the shops where some large milling operations were being carried out. In this department there was a large Ingersoll milling machine which faced off sixteen of

D. Beecroft, Ker of Scotland, and A. L. McMurtry

Mr. Souther's presentation of the Ford car was amusing

the engine supporting arm faces at a time, eight on each side. This machine takes the place of four machines which formerly carried on this work.

Passing to the block testing room in which each of the engines are tested before they are mounted in the chassis, the full set of seventy-five engines were seen running on separate blocks. Each of the motors is given a thorough running test here under a moderate load of about 10 horsepower. The racks upon which the motors are carried are of special design and attracted the interest of the entire party. Mr. T. B. Browne, president of the Institute of Automobile Engineers, was particularly interested in the explanation of the guide of these racks. It is possible to turn the motor upside down in less than a minute and to adjust the bearings by simply removing the bottom of the crankcase which arrangement seemed very ingenious to the visitors.

In the bearing department a special feature of interest is the method used in placing the babbitt in the brass bearing caps. The babbitt metal has no affinity for brass. Solder, however, has an affinity for both brass and babbitt, so that babbitt liners are put on after the brass bearings have been tinned. The solder forms a binding strip between the babbitts and the brass.

New Machines Interest Visitors

The manufacture of the smaller parts brought in some machinery which was new to the English guests as well as to many of the American visitors. In making the shackle bolts for the springs a revolving fixture is used which feeds to the cutters 3,500 bolts per day. A shackle bolt passes through the machine every 45 seconds.

The assembling work throughout the plant was examined with the greatest care. In the motor assembly department the crankshafts were set up and run by belt in their own bearings and then taken down and the bearings scraped by hand. The Cadillac car uses five main bearings which amount to a total of 95.75 square inches of bearing surface. All of this surface is gone over by hand, not a shim being used in the motor.

In assembling the connecting-rods the lower bearing cap screws are very carefully made. This is an exceptional piece of work as the screws are first done in the rough to within .001-inch limit and are then sent through a special burnishing tool through which they must come within .0005 inch. The lower end of the connecting-rod itself its ground to .001 inch and the exterior of the bearing bushing is ground within the same limit. This gives two ground surfaces against each other in this bearing.

Before visiting the testing room of the plant in which all the chassis receive their work-out instead of on the road, the party was conducted to the room in which they were originally assembled and there found a series of tables at which tea and bread and butter were served. At the close of this repast H. M. Leland presented each of the English visitors with a gold Cadillac fob.

The two presidents, T. B. Browne and Howard Marmon

The testing room proved of great interest. Twenty-two Sprague dynamometers were arranged along the longitudinal walls of the room. In each of these a chassis was passing through what corresponds to the road test.

The chassis is backed into place and a hydraulic jack lifts the rear wheels from the ground. In 10 minutes the wheels are connected by chains to the dynamometer and the entire driving mechanism is put through a 3.5-hour test. During this time the car is run an hour at a speed of 30 miles an hour and 10 minutes on the lower speeds and reverse. Various speeds are tried and any noises which develop are carefully noted by the attendant who is in charge of two testing stands. The road test is entirely eliminated and a great saving results.

Detroit Banquet Well Attended

DETROIT, MICH., June 3—*Special Telegram*—The most successful banquet in the history of the S. A. E. was held tonight at the Pontchartrain. Seated at the tables were men of the greatest prominence in the industry both of this country and England. Howard Coffin acted as toastmaster.

Howard Marmon, president of the Society of Automobile Engineers, made a short address on the welcome accorded to

Henry Souther and George W. Houk, donor of the Ford car

The two secretaries, Coker Clarkson and Basil Joy

Group of engineers, T. B. Browne and Henry Ford in the center

the visiting engineers of both countries by the city of Detroit. He thanked the city of Detroit for the freedom of the city and for the symbol given to the engineers of both bodies in the form of the engraved parchment granting the courtesies of the greatest city of the industry. T. B. Browne, president of the I. A. E., was introduced as one of the pioneers of the industry in Great Britain. In 1900 he was an active participant in the 1,000-mile test run given the old single-cylinder horizontal engine of that day. His speech was one of thanks for the hospitable welcome given the English visitors.

Browne on American Hospitality

Mr. Browne said: "You are the most hospitable nation in the world. I am impressed by the organization of the industry in your country, particularly as it is in Detroit. A perfect Niagara of cars streams forth from the factories here. We are also impressed by the beautiful city. Detroit reminds us of Paris more than any other city we have been in. You have made enormous strides in the past 20 years and in a short time you will have nothing but automobiles here.

"Fuel, of course, is a serious consideration with you, as with us. It now costs 1 shilling 9 pence a gallon, but we may soon use kerosene, especially for the commercial vehicles, and we have hopes of being able soon to use a coal product. We admire the care used in the work here and we hope to emulate the standardization which you have worked out so well here but which is apt to be much slower of establishment in England.

"We feel at home here, not as if we were in a foreign land, and your jokes appeal to us in spite of the story that an Englishman cannot see a joke."

Swetland, Prestwick and Houk reading the latest

Mr. Browne concluded with some appropriate words of thanks for the freedom of the city extended by the Mayor and for the parchment proclaiming the same which was presented to the I. A. E.

T. C. Pullinger, one of the English engineers, in speaking on the subject of production in a motor car factory said: "You must know your business before you can be a success in it. What is needed most in a factory is men who will operate the machines as you want them to be operated. It is not a bit of good taking a lot of engineers to work machines in your factory because it is the most difficult thing to teach them how to operate them as they should be operated. They all think they know more than the factory manager. In Scotland I looked around for soldiers and sailors who were ready to go to work and I found them willing to learn what you want to teach them. At the present time these men are doing better work in their several operations than many of the educated men we have.

Reduce Dead Charges

"To make a motor car factory successful you must first of all get away from dead charges or what is known as non-productive labor as much as possible. Inspection departments are good but it is better policy to teach your men to do accurate work. If you get your men to make the parts accurately you have accomplished one of the biggest things in the automobile shop. Try in this way to reduce your dead charges and you will reach eventual success."

H. M. Leland, president of the Cadillac Motor Car Co., gave what he characterized as a little shop talk. This was really a look into the future and it showed how the ideal car will have to be made under a combination of ideal production methods by which all factors entering into the making of such a vehicle will be of the most efficient character. Mr. Leland dealt with the ideal automobile plant, that which might be and will be in operation at some distant time; he said the success of such a plant depends upon a combination of ideal conditions. He explained how this ideal car, which he said had not yet been produced, could be a success and be manufactured so that its factory could pay dividends. It is made possible by just two words—knowing how. Just as it is necessary to know how to breathe before one

Starbuck, Treasurer and Director of the Haynes Automobile Co.

French Car Workmen Clamor for 5.5-Day Week

Majority of Plants Crippled—All Italian Works Are Closed—Altogether 8,000 Men Are Affected

PARIS, May 24—Trouble has again broken out among the workers in the French automobile factories with regard to what is known as the English week. For some time past there has been a strong movement towards the closing of the factories on Saturday at noon, as is done throughout practically the whole of England. This has been done in a few of the factories, among them being Delaunay-Belleville, Hotchkiss, Gnome Aviation Motor Works and the Goodrich tire factory. The present discontent began with the bodymakers, such leading firms as Belvalette, Labourdet, Rothschild, etc., being affected. It spread to the bodyworking department of Bayard-Clement, and from there has spread to the engineering section. A large number of the workmen at the Bayard-Clement factory are now on strike. The Delage factory was affected to a slight extent, but after an explanation by the owner the question was submitted to a private vote and a small majority decided against a strike. In view of possible disorders at the Bayard-Clement factory gendarmes and soldiers have been called out.

Practically all the Italian factories have been closed for the last 60 days, the workmen asking for an increase in wages which the manufacturers refuse to grant. Altogether 8,000 workmen are affected, the shops closed by reason of the strike being Itala, Fiat, Isotta-Fraschini, Bianchi, Aquila, Storero and Spa.

Connecticut's Wood for Automobile Use

HARTFORD, CONN.—The manufacture of automobile bodies is conspicuous among the wood using industries of Connecticut. Automobile body construction demands ash in greater quantities than any other kind of wood, and its immense production of this wood places Connecticut in a leading position. Out of the total quantity of ash used annually in the construction of vehicle and vehicle parts over one-quarter, or 26 per cent., is grown in Connecticut. The exceptional strength of this wood combined with its light weight renders it a favorite for body framework. Yellow poplar, or white-wood, is the other important body wood and meets an exacting demand for panel work. Because of its fine grain and the fact that it is soft and easily worked, besides having a special capacity for holding paint, it is the favorite wood with builders of high-class automobiles and other vehicles. Another wood worthy of mention is cypress, although it is not used as yet in any very great quantities. This wood, however, is growing in favor as a panel wood for fine vehicle bodies.

NEW YORK CITY, June 4—Fred J. Wagner has been made vice-president of the Ajax-Grieb Rubber Co. He will superintend the company's tire sales.

State Registration Running High

COLUMBUS, O., June 2—During the first 4 months of 1913, more than 67,000 automobile licenses have been issued in this state, as compared with a total of 63,117 for the entire year 1912. Up-to-date receipts of $278,729 exceed those of last year by $3,000.

SAVANNAH, GA., June 1—The first 4 months of this year show a state registration of 20,078 cars as against 14,000 for the same period last year. The other southern states have also made considerable progress, the comparative figures being as follows: Tennessee, 1913, 11,225 and 1912, 7,181; Florida, 9,978, 4,896; Alabama, 4,350, 3,360; North Carolina, 7,000, 4,000; Arkansas, 4,500, 3,360; Virginia, 7,000, 4,000; Mississippi, 3,079, 2,000; Kentucky, 7,500, 4,000.

AUSTIN, TEX., May 31—There are at present 10,026 automobiles in San Antonio, Dallas, Houston and Fort Worth, which four cities have an aggregate population of 340,830, the population per automobile being 36, 31, 28 and 45 respectively.

MADISON, WIS., May 31—Alexander J. Cobban, in charge of motor registry in the secretary of state's department of Wisconsin, predicts that the Wisconsin pleasure car registration for 1913 will reach 30,000. On May 12 the registry passed the 25,000 mark, and on May 21 license No. 26,442 was issued, meaning that on May 21, 1913, the registry was nearly 900 in excess of the total registry for the entire year of 1912.

Peugeot and Benz Break Climb Record

PARIS, FRANCE, May 26—Originally held by the local champion Deydier, on a Cottin-Desgouttes car, the record for the Limonest hill climb was this year broken twice. First Georges Boillot, on the Peugeot, 1912 Grand Prix model, similar to the two taking part in the Indianapolis race, lowered the record from 2.24 to 2.07. A few minutes later Fritz Erle on a 200-horsepower Benz clipped the time to 2 minutes 2.5 seconds. As the hill has a length of 2.32 miles, the average speed is at the rate of 68.26 miles an hour. The gradient varies from 2 to 7.5 per cent., and the hill is marked by two very difficult turns, almost impossible to take at full speed. The victorious Benz is a special four-cylinder racing model with which Erle broke the Gaillon hill-climbing record last year at an average speed of 101.5 miles an hour. The car has a bore and stroke of 7.1 by 7.8 inches, and is chain-driven. Boillot's Peugeot, which came second, is a smaller car, measuring 4.3 by 7.8 inches bore and stroke. Third place was secured by Champoiseau on a Th. Schneider car intended to be run in this year's French Grand Prix at Amiens.

The fastest time in the touring car section was made by a six-cylinder Gobron-Brillie driven by Pons in 3 minutes 4.4 seconds. Second place went to Descours on a Turcat-Mery touring car, defeating a six-cylinder Peugeot entered in the higher class. The Peugeot, however, had the disadvantage of running with a wind-resisting closed body. René Thomas, who is scheduled to drive one of the Schneiders in the French Grand Prix, made a good showing with one of the 3-liter models on a touring chassis in 3.32.6 seconds. Juvanon, also on a Th. Schneider, won his class with one of the sleeve valve models in 3:54.5.

Results, Racing Cars

No.	Car	Bore and Stroke, Inches	Driver	Time
1	Benz	7.1 by 7.8	Fritz Earle	2.02.5

Ninety-Eight Trucks Entered in French Trials

PARIS, FRANCE, May 26.—Instead of a series of trips around Versailles, tbe ninety-eight commercial vehicles entered for this year's French trials will be sent on a journey across France with Lyons and Bordeaux as the extreme points. Tris competition, which is almost exclusively a military event, is organized witb a view to testing the endurance of tbe trucks and tbeir suitability for participation in the military subsidies. If a vehicle accomplishes the tests in a successful manner the manufacturer has tbe advantage of selling all duplicates of this model as army subsidized types, the purchaser receiving an annual subsidy and entering into an agreement to hand over the truck to the military authorities in case of mobilization.

This year's trials will last from July 1 to August 12. The first 3 days will be occupied in weighing and sealing tbe vehicles at Versailles. From July 5 to 12 a series of runs will be made from Versailles, the daily distance being from 60 to 90 miles, the fuel being gasoline. On July 16, 17, 18, 19, and 20 town to town runs will be made under full load with carbureted alcohol used as fuel. After a rest at Dijon tbe competing machines will continue to Lyons, Montbrison, Clermont-Ferrand, Limoges, Perigueux, and Bordeaux, carrying full load and using benzol. A day's rest will be allowed at Bordeaux, tbe return to Versailles being made in five stages, through Angouléme, Poitiers, Tours and Chateaudun, using gasoline as fuel. August 8 and 9 will be rest days, and the 3 following days will be occupied in dismounting the various organs of the machines in order to judge the amount of wear that has taken place. The firms entered in the trials are tbe following: Delahaye, Panhard-Levassor, Balachowsky & Caire, De Dion Bouton, Rochet-Schneider, Berliet, Motobloc, Delangere & Clayette, Latil Saurer, Brasler, La Buire, Peugeot, Clement-Bayard, Lorraine-Dietrich, Aries, Cohendet and Cottin & Desgouttes.

RACINE, WIS., June 2.—Of the 120 Racine manufacturing concerns that will exhibit in the first annnal Made-In-Racine exposition, to be held in the new J. I. Case foundry at Lakeside, Racine, from June 9 to 14, under the auspices of the Racine Commercial Club, nearly fifty are manufacturers of and will exhiblt motor cars, parts, accessories, bodies, etc.

FINDLAY, O., May 26.—Beecber W. Waltermire has been appointed trustee in bankruptcy of the Findlay Motor Co., recently sold to L. E. Ewing, its promoter, for $50,000. Tbe debts will aggregate $158,000, wbile claims to the amount of $121.000 have been allowed.

Two Killed in Grand Prix Practice

PARIS, May 23.—While training for the French Grand Prix, Guido Bigio, chief engineer of the Itala Co., and his mecbanician, Giovanni Abrizzon, were killed in the neighborhood of Dieppe yesterday morning. Bigio, who had been connected with tbe Itala factory at Turin for about 7 years and was somewhat recently appointed technical director, was tuning up tbe cars specially built for the French Grand Prix race next July.

PARIS, FRANCE, May 27.—An examination of all the circumstances under which the Italian engineer, Guido Bigio, and his mechanician met their deaths while practicing near Dieppe for the French Grand Prix point to the fact tbat the Itala race driver attempted wbat appeared to be a fairly easy turn at too high a rate of speed. The road on this portion of the old course comprises some magnificent straightaways, a short portion of a switchback nature and a very fine down grade into Eu. One of the sbort rises was followed by a fairly easy bend. It is supposed that the Itala engineer came up to this rise at a very high speed to discover that he bad to make a turn. His rate of speed was too bigh to get round correctly, the car skidded violently, grazed a tree, taking the bark off for a beight of 10 feet, and turned over, coming to a stop in the ditcb with the four wheels in the air.

Milwaukee's Inter-Club Run

MILWAUKEE, WIS., June 2.—Saturday, June 28, has been selected as tbe date for tbe first annual Milwaukee Inter-Club, a team match trophy tour between the Milwaukee Atbletic Clnb and the Milwaukee Automobile Club. The run will be modeled along the lines of the annual competition between the Chicago Automobile Club and the Chicago Athletic Association.

WASHINGTON, D. C., June 2.—The Washington Automobile Racing Association has been formed to conduct a series of race meets on Benning track. The first event is scheduled for June 21.

View of the Turcat-Mery touring car, which was second among cars of this class in the Limonest hill-climb, at the beginning of the upward gradient

Wreck of the rotary valve Itala, in which Guido Bigio, chief engineer of the Itala company, and his mechanician were killed near Dieppe, France, while practising for the Grand Prix

Case and Pierce Defeat Stephenson Truck

Weed Is Granted an Injunction Against Makers of the Federal Grip—Cole Capital Raised to $1,000,000

Knight Motor Finds Truck Field in Europe—Benz Importers Lose Froelich Suit

MILWAUKEE, WIS., June 2—Judge W. J. Turner of the Circuit Court of Milwaukee county found in favor of the defendants in a decision handed down in the suit of the Stephenson Motor Truck Co. of South Milwaukee vs. the J. I. Case Threshing Machine Co. and Pierce Motor Co., of Racine, for $100,000 damages on the claim of breach of contract. The finding of Judge Turner in favor of the Case and Pierce concerns is virtually a dismissal of the suit. The costs are taxed against the plaintiff.

The Stephenson Motor Truck Co., of Milwaukee, with works at South Milwaukee, entered into an agreement with the J. I. Case Threshing Machine Company, of Racine, which had at that time effected an affiliation with the Pierce Motor Co., and since absorbed this concern, to purchase its entire output of delivery cars for a certain period, at the end of which the Stephenson company was to be purchased by the Case company under certain conditions. By this means the Case company virtually became a factor in the motor delivery car field, having previously entered the pleasure car field as marketer of the output of the Pierce Motor Co.

However, the Stephenson product did not come up to the expectations of the Case company, and when the time came for the consummation of the agreement, the Racine concern refused to proceed, claiming that the Stephenson company's product was not up to specifications. Upon the Case company's refusal to purchase the Stephenson company, the latter brought suit to enforce the agreement, and asked for $100,000 damages due to the loss of business and inability to market its own product because of the arrangement with the Case company.

Since the beginning of the suit the Stephenson company has been marketing its own product and intends to continue to do so. The Case company has not made further efforts to engage in the delivery car field and confines its motor car business to the manufacture of Case passenger cars.

Federal Chain Injunction Issued

NEW YORK CITY, June 3—The Federal Chain & Mfg. Co., as well as James Millard & Son Co., William F. Holroyd, Maurice H. Cormack and Frederick Cormack were enjoined from manufacturing chain tire grips which were claimed by the Parson Non-Skid Co., Ltd., and the Weed Chain Tire Grip Co. to be infringements of the Weed patents. The preliminary injunction was issued by Judge Lacombe in the U. S. District Court, Southern District of New York, on the strength of the fact that the grips resemble closely the products which brought about the injunction against the makers of Atlas chains.

Cole Doubles Capital to $1,000,000

INDIANAPOLIS, IND., June 2—Application has been made to the Indiana secretary of state for authority to increase the capital stock of the Cole Motor Car Company, Indianapolis, from $500,000 to $1,000,000. The company has adopted plans for increasing its manufacturing facilities to a large extent.

Motor Wagon Co. Adjudicated Bankrupt

DETROIT, MICH., May 24—The Motor Wagon Co. of this city was adjudicated bankrupt on May 12. A meeting of the creditors will be held here in June to arrange matters.

NEW ORLEANS, LA., May 27—Freight rates on practically all of the European lines to South America were raised May 1. The increase in many cases amounts to 20 per cent. This will be a decided advantage to the American manufacturer of motor cars.

Knight Motor Used on Trucks

LONDON, ENGLAND, May 24—The Knight sleeve valve motor is being used considerably in the commercial field in Europe. The Daimler company, of Coventry, has to date 250 buses and trucks with Knight motors in commission and is at present building 450 buses for the London service, these being equipped with four-cylinder motors 4.33 by 5.91 inches bore and stroke. The chassis of these buses are so designed that they may be used for truck purposes. Forty of these buses have now run an average of 20,000 miles each on the London streets carrying their average load of 40 persons. They are built with a gear ratio of 7 to 1 and are frequently called upon to do 25 miles an hour which means 1,600 revolutions per minute of the motor.

There are several of the Knight type trucks in use throughout England and on the Continent. One bus operating in Constantinople takes in in fares $40.00 per day, seven are running in Munich, Germany, and others in different cities. Recently a sample bus has been placed in the service of the Fifth Avenue Coach Co., New York City.

Froelich Wins Against Benz

NEW YORK CITY, June 4.—The Benz Auto Import Co.'s two suits against Jesse Froelich, its former manager, were dismissed with cost yesterday, when they came up in the Supreme Court of New York before Justice Erlanger. The first suit was for $7,500 in payment of two Benz cars, and the second for $22,500 in payment of 225 shares of stock of the American company. J. S. Epstein, attorney for the defendant, showed to the satisfaction of the court, that Mr. Froelich, in the matter of the first suit, had sold to the home Benz company at Mannheim, Germany, $15,000 of stock formerly his property, half of which was paid for in cash by the German company and half in the form of two Benz cars delivered by the New York concern, who charged the Mannheim company with it, against a credit of the latter with the New York company. This was shown by the books of the Benz company. As for the 225 shares of stock of the New York company, these were transferred to the German company by its American legal representative, Walter Mass, as the stock books of the New York concern showed. On the strength of this proof, the jury dismissed the suits, with payments to be borne by the Benz Auto Import Co.

Automobile Securities Quotations

STOCKS this week varied but little from the prices of last week, due to few developments. Trading was limited.

A. C. of C. Will Revise Car Warranty

Committee To Arrange Details—Evans Moves to Nashville—Luverne Has New Unit Power Plant

Ford's Machinery Moved from Buffalo to Detroit—Remy Company May Make Oil Engines

NEW YORK CITY, June 4—A revision of the standard warranty on passenger cars was proposed by the members of the Automobile Chamber of Commerce who were present at the monthly meeting of the board of directors today. These were: Charles Clifton, W. E. Metzger, W. T. White, W. C. Leland, G. W. Bennett, L. H. Kittredge, F. T. Davis, Jr., J. N. Gunn, H. H. Rice, C. C. Hanch and A. L. Pope.

Mr. Metzger resigned as representative of the Maxwell Motor Co., Inc., but was re-elected to the board as representative of the Argo Electric Co., Saginaw, Mich.

The committee for warranty revision is composed of Messrs. Hanch, Rice and White. The show committee of the body was given the task of working out details for the coming Chicago and New York shows. A request was received from the A. A. A. to co-operate with it in the fight against truck legislation now pending in New Jersey and this matter was referred to the legislative committee.

The next meeting will be held at Christmas Cove, Me., on July 18.

LOUISVILLE, KY., June 2—The Ten Broeck Tire Co., capitalized at $250,000, announces the opening of its plant on June 10 for the manufacture of pneumatic and solid tires in all standard types, both plain and non-skid. The tire is named for Kentucky's famous race horse Ten Broeck. The factory is located at Twenty-sixth and Courtney streets. There are 55,000 square feet of floor space under one roof. The officers of the company are H. L. Lewman, president; Fred Haupt, vice-president; W. N. Cox, treasurer, and Dr. F. L. Koontz, secretary.

DETROIT, MICH., May 31—The Evans Motor Car Co., which has absorbed the Automobile Mfg. & Engineering Co., a former Detroit concern fathered by R. H. Evans, has definitely located its plant at Nashville, Tenn., where a complete factory for the manufacture of commercial cars and motors is to be built, according to Mr. Evans. The Evans company was organized March 20 under the laws of Tennessee with a capital of $50,000, which, however, is soon to be increased to $200,000, it is stated. The factory is to measure 60 by 200 feet and 500 trucks are to be made the first year with a force of men in the neighborhood of 500. The Evans car has a capacity of 1,500 pounds and is equipped with a 30-horsepower Continental motor and a Timken rear axle.

Luverne Has New Unit Power Plant

LUVERNE, MINN., May 31—The Luverne Automobile Mfg. Co., of this city, have placed upon the market a four-cylinder, unit power plant which is completely equipped, consisting of motor with carbureter and high-tension magneto attached. Multiple-disk, dry-plate clutch, selective transmission, with control levers and pedals attached and connected are included in this power plant. If desired, the motor is equipped with electric generator and starter.

Ford Buffalo Branch Moves

BUFFALO, N. Y., May 31—Employees of the Ford Motor Co. branch at Kensington avenue and Liberty street were paid off Friday afternoon and preparations at once were made to ship all machinery of the plant to Detroit, where the firm has contemplated removal for some time. The recent labor trouble and strike in the local Ford plant hastened action of the firm in removing its machinery to Detroit. About 500 men were regularly employed in this plant.

INDIANAPOLIS, IND., June 2.—There is an unconfirmed rumor that Frank and Perry Remy of Anderson, formerly owners of the Remy Electric Co., expect to engage in the manufacture of kerosene oil engines. They have been engaged in secret experiments for several months and have been negotiating for a factory. It is reported that within a short time the Remy brothers will be ready to make public their plans for the future.

NEW YORK CITY, June 2.—The Grimm ordinance abolishing private stands for taxicabs in New York City and the leasing of the streets in front of hotels by the proprietors of the latter and reducing the rates for taxicab service was passed last week by the Board of Aldermen's vote of 65 to 1.

WASHINGTON, D. C., June 2.—Recognizing the great question of good roads the Democratic caucus of the House of Representatives today created a committee on roads, with Representative Dorsey Shackleford, of Missouri, as chairman.

NEW YORK CITY, June 3.—A meeting of the creditors of the bankrupt New York Motor Works, Inc., Newark, N. J., has been ordered by the Chancery Chambers in Newark for June 24. At this meeting the creditors and stockholders are to show cause why the receiver's account now on file should not be allowed, allowance for the receiver's services made, a 66 per cent. dividend with interest paid and a final dividend paid out of the money remaining in the hands of the receiver after this payment.

NEW YORK CITY, June 4.—The Brady-Murray Motors Corp., distributor of the Chandler six cars and the Maccarr, Lansden electric and Smith commercial vehicles, has leased the first two floors of the new eleven-story building under construction at 245 West Fifty-fifth street. The company will move into its new quarters July 1. R. J. Laciar is sales manager.

ANDERSON, IND., June 2.—G. A. Lambert and James A. Burk have bought the interests of B. F. Lambert, president of the Buckeye Mfg. Co., Anderson, Ind., which builds Lambert motor cars. They have been interested in the company for some time. B. F. Lambert has bought a controlling interest in the Elwood Iron Works, Elwood, manufacturers of heavy castings and of an oil engine recently perfected by David Morrison, a machinist of Anderson.

NEW YORK CITY, June 3.—The Packard Motor Car Co. has declared a quarterly dividend of 1¾ per cent. on its preferred stock.

Market Changes for the Week

TIN slumped this week to $46.55 per hundred pounds. The market was unsettled and irregular and still below the cost of importation from London. Copper was dull and heavy, the consumers here and abroad buying sparingly and the speculators showing small interest. Both electrolytic and Lake coppers dropped in prices, the former $.00 3-10 and the latter $.00 1-4 per pound. Lead was dull but steady, remaining constant at $4.35 per hundred pounds. Bessemer and Open-Hearth steel rose $1.50 and $.50 respectively. Automobile tire scrap held firm at $.10 per pound. Cottonseed oil rose $.05 per barrel, though there was decided weakness on Tuesday due to a break in lard. Petroleum prices remained firm and unchanged and the consumption was liberal. Linseed oil was quiet and unchanged. Gasoline, rapeseed oil, sulphuric acid and antimony remained unchanged.

The Visiting English Engineers

IT is to be hoped that more visits between foreign and American engineers will take place, now that the ice has been broken and both sides have taken the first step. American engineers learned much when abroad a couple of years ago and already all of the foreigners are pleased with the insight they have been given of American production methods. There are always two sides to a question and there is no better way of making progress than to get together. The automobile is an international creation, a machine built in a particular country but used in all the lands that make up the continents. The get-together spirit is needed more than in many other industries. The greater the standardizing work that can be mutually accomplished the better for maker and consumer. Visits of this nature are bound to bring people closer together and in this age of international congresses of peace, international congresses of good roads, international congresses of commerce and international congresses of government and chambers of commerce, the automobile industry would not be keeping step with the march of progress if it failed to work for closer international relationships in matters of design, manufacture and production. It is to be hoped that annual visits may be stimulated, or if once a year should prove too frequent, not more than 2 years should be the interval between visits.

Unpreparedness Is Costly

INDIANAPOLIS' 500-mile race was slower this year than last because of unpreparedness on the part of several contestants and because of much greater caution in driving by not a few of the best-known pilots. True the motors were limited to 450 cubic inches displacement as compared with 600 cubic inches a year ago, yet this reduction of 25 per cent. in capacity was not the major reason for the reduction in pace for the entire distance.

Scarcely one-half of the cars were racing fit. Some of them were not any more fit to start in the race than a drug store clerk would, without training, be fit to start in an Olympic marathon. Others had new motors, new sets of cylinders being put on the day before the race, and nothing but dropping out before the race was well under way was all that could be expected. With other entrants there was not sufficient time previous to the race, to test thoroughly the running gear parts and gasoline tank leaks gave more trouble than motor defects.

In spite of the years of experience American makers have had in preparing cars for severe contests, a majority of the factories are slow to learn the lessons of the early bird. Last week's race has proven once more that the car to endure the gruelling punishment of 500 miles is the car that has been well run in, several of the foreign cars that finished having had many thousand miles of previous running.

It is one thing to design and build a racing car and it is another thing to get it ready for the race. The best-designed and best-built car in the world will generally fail signally in a contest if it has not been previously prepared for the fray; whereas a relatively inferior machine may make a surprising showing if it has been well groomed for the work. The cylinders must be worn in; the bearings must be worn in; and a hundred other parts must be worn in. After being worn in the motor or other part has to be taken apart, every iota of worn material removed, every part thoroughly cleaned and then re-assembled ready for the final trial run.

The exceptional amount of oil on the track held the speed down considerably, a fact which led to the utmost conservatism, translated by many as being good judgment in order to get a share of the $50,000 prize money.

The enormous consumption of gasoline and oil by some contestants directs attention to making fuel economy a factor in such a race, a factor only in that a contestant must not use in excess of a determined maximum. Such a regulation would apply with equal effectiveness to lubricating oil also. In last week's race one car averaged 23 miles to the gallon and landed well up with the leaders. Compared with this some others averaged but 5 miles to the gallon.

This year's victory of a foreign car is bound to give this classic a greater following a year hence, in fact, it will be surprising if the $50,000 does not attract a galaxy of foreign racing stars and the premier racing machines of Europe. Those who participated this year will surely return and each is bound to bring others over because of his tale of American gold. Viewed from a contest viewpoint the French victory will do more to stimulate American entries next year than if an American made machine had won.

The Growing Popularity of Electrics

From a Paper Read by H. H. Ricè at the Recent Convention of Electric Vehicle Makers in Boston.

THE encouraging feature of the growth of sentiment in favor of electrics is not limited to those who derive profit from them. The public itself acknowledges the desirable features of the electric car in ever-increasing numbers. There are thousands of owners of automobiles, who, if they were to make their automobile investment over, would find in their stable a place for an electric. They will do this eventually, as is shown by the large number of gas cars which are traded in for electrics and many more which are offered in trade.

Another indication of the growing popularity of the electric is that manufacturers and dealers in gasoline cars have changed their attitude of outright contempt or good-natured tolerance to recognition that the electric, both in the passenger and truck vehicle, is a car which in its own field is unequaled by the gas car.

Only a few years ago, the manufacturer of a gasoline car looked upon the electric as a toy or a car for the woman or the man who did not dare, but today they have been forced by figures of cost and maintenance to acknowledge that the electric cannot be ignored for service and that in spite of self-starters and all the other improvements the electric is par excellence the car of convenience for city use.

Electrics Really Necessary

It hardly seems in place to argue for the growing popularity of electric vehicles to those who are entirely familiar with the fact, but sometimes we do not see best the things that are nearest to us and when we hear of the tremendously large scale of gasoline vehicles we wonder if the electric is really growing as fast as its friends and well wishers would have us think. But it is really becoming an important numerical factor.

According to THE AUTOMOBILE there were in October, 1912, some 33,842 electric pleasure cars registered in the United States, while the new registration for the year was 5,550, showing a growth of 20 per cent. These figures show that there are half as many electric vehicles in use in this country as there are automobiles of all types in France or any other of the leading countries of Europe.

At present there is no accurate way of obtaining a definite report on the actual number manufactured except by very tedious inspection of the registration records and from these, owing to the different laws of the various states, it is difficult to obtain satisfactory information.

However, one only needs to look about and to count the large number of new firms manufacturing vehicles to know that at least from that source there are a great many electrics being placed on the market. Then, by noting the number of new vehicles of the older manufacturers which are seen on the streets, further proof is added of the increase. One has but to look about him in any city of the country, except the East, perhaps, to realize to what extent electric vehicles are used, and even in the East itself people are beginning to take up the electric pleasure vehicle.

For a number of years, indeed, certain sections of the East have shown a larger use of the electric commercial vehicle than anywhere else in the country.

It is generally considered in the automobile trade that the gasoline car and the electric occupy different fields and there should be no active competition between them. It is a fact, however, as we all recognize, that many owners of gasoline touring cars have become so accustomed to the use of their machines that they employ them without considering the cost in daily service, to and from business and in their pleasure rides in and about the cities in which they live.

The general use of high-priced touring cars for both city and country service is one of the most expensive and uneconomical fads of the day. It is much the same as if the carriage owner of 50 or 100 years ago had insisted on driving a stage coach on city streets because it was necessary to use such a vehicle for long-distance work on country roads.

The electric pleasure car as it is built in this country fills the place of the fashionable pleasure vehicle as it was used before the introduction of the motor vehicle. It has all the speed allowed, or mileage necessary, within the city limits.

It is built with greater luxury than the most fashionable carriages of the last generation and it has every advantage over the gasoline car for daily service. It is simpler in construction, free from all the mechanical troubles that beset the gas car and far more economical to maintain than any gas car.

The man who has $4,500 to invest in automobiles will do well to consider whether he can find a better investment than a $3,000 electric for city use plus a $1,500 gas car for touring purposes.

It is now 21 years since the first electric vehicle was seen on the streets of Chicago, but it was 5 or 6 years after that that they began to be manufactured. If it were not for the phenomenal growth of the gasoline during these later years, the increase in the use of the electric vehicle would itself be considered phenomenal.

The growth of the business has never taken on boom proportions and hence has not been subject to the fluctuations that have affected the gasoline car industry. The increase in the demand for electrics has been sufficiently moderate to be a normal and healthy growth and it has never been stimulated by an extraordinary amount of free publicity.

Yet the electric has done a very, very large amount of straight advertising in proportion to its business and the advertising done by the manufacturers has always been in advance of the volume of business. They spend a larger percentage of their gross business on advertising account than almost any gas car company.

It is accordingly not surprising this year to find the manufacturers of electrics working at full capacity and in some cases increasing their product over last year's business, a result that can be largely attributed to the increased advertising.

Today there is no manufacturing industry in the United States that is more firmly established, more safely within the bounds of its legitimate field than the electric automobile business.

As for the car itself, it may well be claimed that while many improvements, small and great, may be looked for within the next few years, as in the past, it is at this moment a highly developed, well-balanced piece of mechanism which runs with comparatively little attention.

What I have said about the general attitude of the public, the central station men and the gas car manufacturers as to the growth of the electric, applies both to pleasure and commercial vehicles, but I cannot help referring particularly to the steady growth of the electric truck and delivery wagon business, and the increasing importance of that side of the industry. The field of the electric pleasure carriage, as now built, is already pretty well defined and its future growth may be predicted with some degree of certainty. The field of the electric commercial wagon has hardly been explored as yet. There is an immense opportunity for the use and distribution of electric motor wagons which remains to be opened and exploited. It is the undiscovered country of the future and the growth of that branch of industry is likely to be one of the phenomenal developments of the next few years.

Commercial Vehicle Growth

This growth of the electric commercial vehicle is all the more remarkable because the comparatively few manufacturers have had to make headway in face of the competition of a hundred manufacturers of gasoline trucks. Nearly every manufacturer of gasoline pleasure vehicles puts a commercial body on his chassis and thus has an outlet for his surplus stock or obsolete styles. He can make a demonstration on pneumatic tires, which will, of course, be excellent in speed and in performance, but day in and day out and year in and year out the electric invariably shows the lower cost per package.

Let us continue persistently to claim for the electric the advantages which it so surely possesses, be careful not to claim superiority in fields where it is not as yet superior, and show by our deeds as well as our words that we believe everything we claim.

Fig. 1—Neat hat for touring in white ratine with rose colored band. Listed at $3

Fig. 2—Smart reversible bonnet in red silk with visor of black flexible hemp straw. $6.50

Fig. 3—Close-fitting gray bonnet with turned over brim and trimmed with bow at front. $2.25

Fashions for the Woman in the Automobile

This Year's Dustcoats Are Smartened with Colored Trimmings—Hats Show an Interesting Variety of Design

THE touring season is rapidly approaching and within a few weeks thousands of happy automobile parties will be skimming along the open highways drinking in the scenery in its springtime freshness. Such a party forms a pleasing picture, always granting that the load of enthusiastic tourists includes a proper complement of members of the fair sex in holiday raiment. None know this better than the ladies themselves and their taste in clothing that combines neatness of appearance with comfort and the peculiar demands of automobile travel is reflected in the extensive display of motor wear at present being eagerly examined at the supply store counters.

Lightness of material and looseness of fit so as to allow that ease from which a considerable part of the pleasure of automobiling is derived, mark the latest developments in motor garments for both sexes. And the designers have so worked that these desirable features are obtained without in the least sacrificing the charm of graceful lines. All through the range of coats, dusters, waterproofs, slip-ons, etc., on the ladies' counters are strong evidences of the hand of the artistic designer.

Perhaps the most noteworthy direction in which development is passing is that of reducing the number, weight and bulk of the garments which it is necessary to carry in order to provide for all possible weather contingencies. Formerly the waterproof was too warm for the midday sun, and the necessity of changing into it at every summer shower was rightly considered a trouble that should be avoided. This brought about the introduction of rubberized garments in gabardine, silk and other materials light enough to perform the ordinary duties of the duster. For a warm showery day these garments are ideal.

Fig. 4—Popular type of linen duster with color relief of blue or red for the collar and cuffs. Listed at $7.50

Fig. 5—Linen dustcoat trimmed with white and tan leather. The oblique front gives a distinctive appearance. Price $29.75

A few years ago it was customary to meet the cold air of evenings with a massive coat whose bulk monopolized an undue share of the baggage space on the car when it was taken off. This has been remedied by the use of garments made from closer cloths, with more attention paid to the correct design of collars and buttoned parts, and by the use of wind shielding devices at the wrists. By these means it is now an easy matter to keep warm without acting as a support for a weighty top coat. This duality of purpose of the lighter wear and reduction in bulk and weight of the heavier renders the all important question of what clothing shall we carry one that can be faced with comparative calm.

In order to provide that freedom of arm movement which is essential to comfort while sitting in the car and also to insure the least damage by crushing to delicate wear underneath the top coat it is the universal custom in motor garments to provide roomy arm holes and shoulders. This perhaps explains the popularity of the raglan type of sleeve, although the particular advantages that were formerly associated only with that cut of shoulder are now incorporated in garments having the regular coat sleeve.

Of all the garments that are necessary parts of the woman motorist's wardrobe none is so indispensable as the duster. This year's display of these garments is bewildering in its variety. Scarcely any are on show that cannot claim a share of attractiveness in one way or another. The introduction of colored trimming of some sort adds considerably to the appearance of many of these summer garments. In Fig. 5 a particularly neat example of this use of contrasting color in a linen dustcoat is shown. In this the collar and wrist cuffs are of tan leather with a narrow border of white, also in leather. The collar is provided with a buckled strap so that close fitting at the neck is an easy matter. Similar adjustable fasteners are attached to the cuffs to keep out the wind. A helf belt of tan and white leather, in uniformity with the collar trimming, contributes to the smart appearance of the back.

Fig. 4 also demonstrates the enhanced appearance that is obtained by the introduction of a slight splash of contrasting color on an otherwise plain garment. This duster, supplied in linens and mohairs, has a collar of a light shade of blue or red with the cuffs to match, and is a most popular type for summer wear.

Linen has the advantage of easy laundering, but where a dustcoat of a more dressy appearance is wanted the prospective purchaser has a wide range of silks and other fine materials placed before her. The duster shown in Fig. 13, for instance, and supplied in pleasing shades of blues and grays, fits the case. It is an extremely light garment and has the advantage of being shower proof. The skirt is long and roomy and the side pockets are of a useful size.

Fig. 6—Tan mackintosh with close fitting military collar and wrist bands. Supplied with raglan shoulders or the ordinary inserted coat sleeves. The wrists have inner wind guards. Price $15.

Fig. 7—Very light, double-breasted shower proof of white rubber fitted with black collar and wrist facings. This garment is furnished with large side pockets with wide flaps. Price $10.

Another silk coat for the dressy motorist is illustrated in Fig. 12. This is in rubberized Italian silk with a convertible collar and raglan shoulders. The sleeves are comfortably wide and are furnished with the conventional buttoned wrist strap. The neat appearance of the collar with the lapels buttoned up is well brought out in the illustration. In the heat of the day when a breeze about the neck is welcome the open position of the collar will be found to look equally well.

A mannish mackintosh of the conventional type is shown in Fig. 6. This is a single breasted garment in tan with a close fitting military collar. Slash pockets at the side are provided and the sleeves are furnished with wind cuffs and outer wrist straps. It is supplied in both raglan and the regular coat sleeve forms.

For those who prefer an extremely light waterproof the white rubber illustrated in Fig. 7 can be recommended. As will be seen, this is a double-breasted garment of a very smart appearance. The collar and cuffs are black, and wind guards are fitted to the wrists. The side pockets are of the patch type furnished with wide flaps. Such a coat can be folded up into a very small compass, and its price, $10, is astonishingly small when its neat appearance is taken into account.

Fig. 11 shows a tan leather coat that somehow seems to suggest that the wearer has a thorough knowledge of the mechanical details of her car. Not that it is designed primarily for the lady driver—it is a handsome garment for any one in the car—but it smacks more of the automobile than those previously described. The leather is extremely soft and pleasant to wear and with the collar raised as shown in the picture forms ample protection against the elements. The single row of buttons pass through a storm flap that produces a perfectly sealed joint

Fig. 8—Mica mask inserted into crepe de chine veil. Ventilating holes are provided. Price, $4.50

Fig. 9—Handsome silk bonnet with veil permanently attached to front of brim. Listed at $12.50

Fig. 10—White corduroy hat that is easy to wear and always looks well. The price is $2.95.

Fig. 14—Left, showing smart side view of silk and straw bonnet shown in Fig. 2. $6.50

Fig. 15—Right, smart sailor straw hat that is useful in the blazing sun. Price $10

Fig. 11—Top illustration shows handsome tan leather coat provided with high, close fitting collar, wrist guards and storm flap under front buttons. The leather is pliable and comfortable to wear. Lined with plaid silk this garment sells for $49.50

Fig. 12—Light, skeleton-lined shower proof in rubberized Italian silk of a pleasant gray shade. The collar is of the convertible type, permitting closed or open neck and straps are fitted to the wrists. It is listed at $42.50

Fig. 13—Bottom illustration shows an extremely light duster in gloria silk, fitted with the conventional lapel collar and wrist cuffs. It is treated so as to resist summer showers and is supplied in various shades of blue and gray. Price, $22.50

to the exclusion of wind and rain. Wind cuffs are also fitted to the wrists.

Turning now to the heavier wear, a general utility overcoat that will protect against the cold snaps of evenings at this time of year and at the same time act as a useful touring garment for day travel during the cooler seasons, is a necessity in the woman motorist's wardrobe. For such a coat the check pattern will always remain popular. The front and back views of a particularly handsome homespun overcoat in black and white check are given in Figs. 18 and 19. The collar is supplied in a light red or blue with piping at the buttons to match. This small relief of bright color from the black and white of the material is an exceedingly happy combination. The lapels are of the flexible order that is becoming increasingly popular, permitting of a close fitting up to the neck when desired. The buttons are of the same check material as the coat. Fig. 19 shows the distinctive appearance of the back, obtained by the use of a diagonally buttoned panel effect.

Another heavy coat that will defy the cold winds is shown in Fig. 20. This is in English tweed of a plaid pattern with a collar in broadcloth of contrasting collar. As will be seen, the buttons are massive and arranged in two sets at the side. A broad half-belt at the back, button-trimmed, agrees with the wide form of buttoned cuffs.

Favorite Colors Are Grays and Browns

Color tendencies this year show the grays and browns to be increasing in favor, these quiet tones being generally relieved however, by a judicious use of small quantities of brighter hues in the way of trimming. The use of belts and the various forms of button trimming has also had the effect of destroying the monotony of line of a garment.

It may not be out of place to mention here the great utility of the ordinary woolen sweater in connection with the wardrobe of the woman motorist. They are easily carried and are generally provided with ample pocket space. This latter is a point which should not be forgotten by the tourist. It will be noticed in respect to other garments, too, that the convenience of these receptacles of gloves and the numerous other things which on tour are always wanted in a handy place has not been overlooked by the makers of automobile wear this year.

The question of headwear has received special attention at the hands of the designers. The automobile hat must have the feature of being easily held to the head in a wind. And a great variety of hoods, bonnets and soft hats are to be had possessing this desirable feature. Fig. 1 shows a ratine hat in rose and white that is flexible and has a neat, comfortable appearance. This type of headwear can stand a good deal of knocking about and therefore is popular with those who mean to have all the fun of a tour without wasting too much thought on the care of wearing apparel.

Fig. 16—Left, reversible bonnet of flexible hemp straw with silk crown covering. Listed at $5

Fig. 17—Right, showing the charming effect of the veil and hat combination illustrated in Fig. 9

Fig. 18—Top illustration shows back view of a smart coat in black and white check homespun. The neat appearance of the back with the obliquely buttoned panel effect will be noted. The collar is of a bright blue or red. Listed at $38

Fig. 19—Another view of the garment shown in the upper illustration, showing the trimming of the collar. This collar has flexible lapels so that they can be buttoned up close or as shown. Piping at the wrists and buttons of the same color as the collar

Fig. 20—Heavy coat in English tweed with yoke effect and novel arrangement of buttons. The wide cuffs and a wide half belt at the back are button trimmed. The collar is in broadcloth of a contrasting color. Price $37.50

The center illustration, Fig. 2, shows a charming bonnet of the visor type. The crown is loosely arranged silk of a bright red shade, while the visor is of black hemp straw with black ribbons attached. A bonnet of this type has the merit of affording protection to the eyes in the sun rays and is close-fitting enough when tied to defy the wind. A view from the side is given in Fig. 14.

A neat hood in light gray with bow trimming of the same material and color is shown in Fig. 3. This hat harmonizes pleasantly with almost any light duster.

For those who use a veil to secure the hat the bonnet shown in Fig. 9 will be found suitable. In this the veil is permanently attached to the front of the hat, which is a gray silk and straw combination. The appearance of this particular hat with the veil in place is shown in Fig. 17.

Fig. 10 shows a popular hat for the sporting tourist. It is a white corduroy and looks exceedingly well in the open against the green background of trees and lawns.

The sailor hat shown in Fig. 15 is useful in sunny weather and is capable of withstanding a good deal of rain without any serious result.

Reversible hats are meeting with a ready demand. The one shown in Fig. 16 represents the most usual design. A flexible weaving of hemp straw is used, covered on one side with a silk crown. By merely turning the hat outside-in the effect of another hat is instantly produced.

The Colored Veil Is Popular

Among the minor details of wear that are of importance to the woman who finds that the continual facing of the wind has a serious effect on the complexion, veils should receive careful consideration. This year a veil that is meeting with much favor is one in which a graded effect of color, somewhat reminiscent of the treatment of skies in Japanese prints, is introduced. The color is deep at the ends where it makes up into a bow with charming effect, and gradually fades into the natural transparency of the chiffon over the face.

In choosing a veil for automobile wear it should not be overlooked that ample size and closeness of material are the two essentials if a real dust excluder is desired.

For the woman motorist who never feels comfortable wearing goggles and yet desires a protection for the eyes the mica mask in Fig. 8 is worth consideration. The plate of mica is inserted into a veil that is tied about the hat, supporting the transparent surface in a suitable position and allowing a wide view.

The Automobile is indebted to James McCreery & Co., New York, for the use of the garments and hats shown in Figs. 3, 5, 10, 11, 13, 18, 19 and 20; to Saks & Co. for those illustrated in Figs. 1, 6, 7, 9 and 12, and to The Auto Supply Co., New York, for the duster shown in Fig. 4 and the hats in Figs. 2, 8, 14, 15 16 and 17. Photographs by N. Lazarnick, New York.

The Engineering Digest

Interesting Attempts by British Engineers at Establishing Objective Standards For Judging the Quality of Automobiles—Results With Naphtaline as Taxicab Fuel—Patent Law Under Revision—Balloon Material For Tops

RATINGS of Cars by Co-efficients K and Sigma—In the *Automobile Engineer Year Book for 1913* (London) 16 pages of text and reference tables are devoted to what is called "the co-efficient K," by the proper use of which it should be possible to compare the merits of design of one motor vehicle with those of another, especially with regard to hill-climbing capacity, if the best possible performance of each vehicle under a given set of conditions is on record, the two sets of conditions not necessarily being identical.

K figures out to a number averaging between 120 and 130 for sporting cars, between 100 and 110 for touring cars and between 80 and 90 for commercial vehicles. It is composed of the factors from which motor power is figured, combined with those giving the total gear-translation (revolutions per minute of engine divided by revolutions per minute of road wheels), the diameter of the driving wheel tire and the weight of the car with passengers. K, standing for these data of construction expressed in one numerical value, represents the chosen design features which should make possible certain performances, and these theoretical performances are tabulated for values of K ranging from 400 to 30, and for different road conditions, the performances corresponding closely, it is stated, to those obtained with the best cars in the market. Now, by consulting these tables and comparing the actual performance of a car which is under investigation, and whose K has been figured out, with the tabulated performance for its K-value, it can be seen whether the performance falls behind the standard or not. If it does, it stands to reason that the design or workmanship of the vehicle falls below the standard of excellence at present attained at the best factories at some one or more of the points which influence the car's work but which are not included in K, or else that the condition of the car has suffered by use or neglect.

Under the title "The Co-efficient Sigma," H. Kerr Thomas proposes in *Internal Combustion Engineering* for April 2 to use another co-efficient which he calls sigma, and which is patterned after the co-efficient K, for comparing the gasoline consumption of different types of automobiles, and the components entering into sigma are so chosen that not only the ton-miles involved in a performance are considered but also the dimensions of the motor and, the author says, its volumetric efficiency and the degree of perfection with regard to fuel economy reached in the carbureter with which the car is fitted, it being apparently the view of the author that these features may have been selected by the car builder or owner for reasons having to do with convenience of operation and considered superior in importance to fuel economy. In other words, the co-efficient sigma serves to determine the fuel efficiency of a car in so far as it is determined by other factors than those most directly concerned, especially by the mechanical frictions in gears, tires, motor and bearings. The road resistance is left out of consideration, however, so that comparative tests should be made over identical stretches of road.

In contrast to this reservation, the tables for co-efficient K, above referred to, are figured out with reference to several classes of road surface, for each of which a certain co-efficient of road resistance is assumed, and those making use of the tables must estimate whether the road over which the performance under investigation takes place conforms nearly enough to one of the types scheduled in the tables or an allowance should be made for the variation.

The co-efficient sigma, as first devised with reference to the factors to be considered, takes the following form:

$$\Sigma\ (\text{sigma}) = \text{Constant} \times \frac{D^2 S N g T}{d W}$$

in which D is bore, S stroke, N number of cylinders, g the total gear ratio, T the presumable gasoline consumption in ton-miles per gallon, (so that 1 divided by T becomes the consumption in gallons per ton-mile), d the diameter of driving-wheels in inches and W the weight of the car in tons. The value of the constant is determined by a consideration of the weight of the air and gasoline vapor theoretically consumed for a given piston displacement per mile, and the weight of the car is supposed to increase this consumption proportionately.

By evolving the equation on this principle, the formula reaches the final form:

$$\Sigma\ (\text{sigma}) = 0.0039 \times \frac{D^2 S N g M}{d}$$

in which M represents miles per Imperial (English) gallon, and in which the weight element has been cancelled out through the fortunate circumstances of being represented in M. For use in America, where the gallon is 1.2011 times larger, the constant is changed accordingly and becomes:

$$\Sigma\ (\text{sigma}) = 0.0047 \times \frac{D^2 S N g M}{d}.$$

By taking the fuel consumption officially recorded for a Rolls-Royce car as an example of good fuel economy and figuring out the value of sigma for its performance, finding it to be 4.7, the conclusion is reached that 5 might be accepted as the maximum value likely to be attained for sigma at any car performance. If fuel other than gasoline of about .750 specific gravity is employed the constant 0.0047 must be modified.

[A cursory study of the system proposed by Mr. Thomas in this formula does not seem to disclose in what manner the volumetric efficiency of the motor and the qualities of the carbureter have been set aside and eliminated from consideration. As these factors are not found among those of which sigma is composed, it seems that they should be among those to be held responsible if a given car performance falls short of the standard.—Ed.]

REVISION of French Patent Law—A government bill is now before the French parliament according to which it is proposed to extend the life of patents from 15 to 20 years, to change the present annual tax of 100 francs to 25 francs for the first year and an additional 25 francs for each succeeding year and to establish a special form of patents for "small inventions" expiring in 5 years and taxed only 25 francs annually. The latter provision is criticised as likely to give rise to ambiguity in distinguishing between great and small inventions as well as eventual dissatisfaction to inventors who for the sake of momentary economy try to get along with protection for only 5 years. The total tax during the lifetime of a patent, according to the new bill, would amount to 5,250 francs, while at present the total is only 1,500 francs. It is mentioned as one of the reasons for proposing lower rates for the first years—the first including the fees for securing the patent—that French inventors now, in order to save initial expense on an invention, frequently apply first in Belgium where the fee is only 10 francs. By doing so, they gain protection for one year, during which they can try to make sure of the commercial value of the invention while still retaining all their rights in those countries which are members of the Patent Union. [The text does not state clearly if the year runs from the date of application in Belgium or from date of issue of Belgian patent. Those who may be interested—since the United States also are members of the Patent Union—are referred to their patent attorneys for responsible information on this point.—Ed.]—From *Omnia*, May 10.

—

TAXI Run 62 Miles on 20 Cents Worth of Fuel.—The fuels now regarded as possible substitutes for gasoline in motors of small size and light weight include benzol, coal spirits (meaning the fluids), practically equivalent to gasoline, which have been distilled in large percentages from coal, especially cannel coal, in England), kerosene, enriched alcohol, dissolved acetylene (absorbed in acetone) and naphtaline; also shale oil products, of which some resemble kerosene and others gasoline. Hereto comes that methods have been devised for combining the highly volatile naphtas contained in crude oil with other constituents of the same raw material in a manner which is almost equivalent to synthetic production of gasoline and immensely increases the percentage of it obtainable from the petroleum fields; it being stated, even, that much of the gasoline now in the market is produced by these improved methods. In making this list, no account is taken of the possibility of developing the Diesel motor to the point of making it applicable to automobile and kindred purposes and getting the benefit of the heavy oils and tars with which motors of this type can be operated in the sizes and weights suitable for stationary and marine work.

Among the proposed substitutes for gasoline, some are susceptible of unlimited production, especially enriched alcohol and acetylene, but questions of cost and adaptation to existing motors have retarded the testing-out of their fitness. The coal spirits, too, are probably obtainable in sufficient quantity to compete effectively with gasoline and limit the upward tendency of its price.

Now, however, the very number of the substitutes coupled with the development of carbureters by which fuels of different density and composition may be successfully handled in connection with motors of the type in common use, or only slightly modified, forces into the background, somewhat, the question of the quantity of each fuel which may be put into the market and raises to greater importance, on the other hand, the question of what may be done with each of these fuels, on the assumption that the field for light motors is broad enough to admit of finding suitable uses for each variety, while all of them in combination will check the fuel famine, with its attending evils, more efficaciously than any one of them could be expected to do. From this new viewpoint, the results lately achieved with naphtaline—so far the cheapest of all the fuels mentioned—gain an interest which is not limited to the European countries, where the fuel question has become one of vital urgency intimately allied with the problems of national defense.

From the tests of naphtaline reported by L. Ventou-Duclaux, one of the engineers of the Automobile Club of France, it appears that this substance might well be used for heavy hauling of earth, rock and ore and perhaps for omnibuses.

The tests were conducted with a Renault taxicab whose 2-cylinder, 12-horsepower motor had been modified for the purpose, the modification consisting mainly in replacing the ordinary carbureter by the apparatus illustrated in Fig. 1, which was developed in two years of experiments conducted by G. Mohr. It consists in the double carbureter shown in subfigures 1 and 2 and the device for melting the solid naphtaline shown in subfigure 3. The latter comprises a receptacle A heated interiorly by leading a coil of pipe from the exhaust around the wire-gauze filter *c* in which the solid naphtaline is placed and which retains the impurities which it may contain. The melted naphtaline runs out through the fine tube *d*, which is so paired with the exhaust branch pipe D that the fuel arrives in the carbureter at a temperature higher than its melting point. The carbureter is also heated by the exhaust gas, which arrives through the wrapped pipe D'. A third branch D" from the exhaust manifold connects with the upper end of the coil *c*. Butterfly valves G and H in these pipes admit of regulating the heat, as between the receptacle and the carbureter. The double carbureter has two float chambers, one for gasoline and the other for the melted naphtaline. The latter is cast in one piece with the atomizing-chamber above the jets, so as to equalize the temperature in these two parts and avoid precipitation of the fuel vapors. The two jets I and I' converge toward the same atomizing-chamber, which is placed, as shown in subfigure 2, between the chamber L, filled with exhaust gas, and another chamber in which the surplus air arrives regulated by a sliding-sleeve and the wingnut *e*.

The naphtaline used in the test was of the crude variety tapped from the still of which the price is 6 francs per 100 kilograms in 5,000 kilogram lots in Paris, near which city it is produced. The test was conducted over a stretch of road 52.7 kilometers long which was covered in both directions. The laboratory engineers of the *Conservatoire des Arts et Métiers* were in charge. The motor was started a few minutes before the beginning of the test, so as to make use of no other fuel than naphtaline for the recorded time.

The results were as follows: The test lasted 3 hours, 19 minutes, 30 seconds. Stops of the motor aggregated 15 minutes 30 seconds, making elapsed time 3 hours 4 minutes. The distance covered was 105.4 kilometers. The road was a macadamized one in good order and with moderate grades. The average speed was 34.4 kilometers per hour with a maximum observed speed for one kilometer of 42.3 kilometers per hour. The total consumption of fuel was 14.996 kilograms, making a consumption of 14.228 for 100 kilometers.

The motor was started on naphtaline without difficulty after injection of gasoline in the cylinders. During the test it functioned normally and regularly, without skipping or knocking. There was little smoke in the exhaust and that only on the upgrades. Restarting after stops was effected without injection of gasoline. On the following day it was ascertained that the compression had remained normal and that the motor was not gummed up but in good working order. No deposits or abnormal fouling of the different organs was observed when it was taken

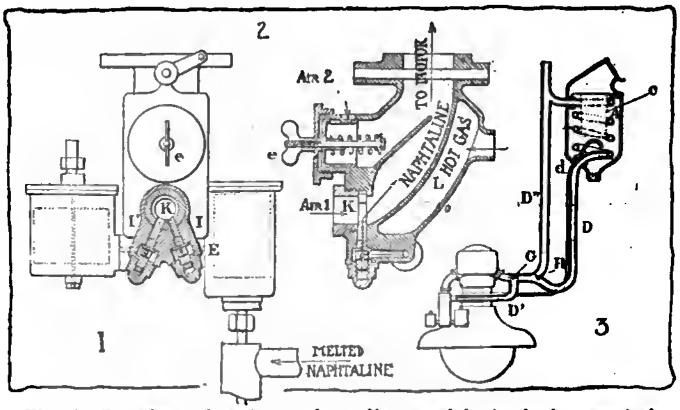

Fig. 1—Double carbureter and smelter used in taxicab operated with naphthaline as motor fuel

apart. There was, especially, no precipitation of naphtaline in the crankcase.

A supplementary test was conducted to find out how long time was required after starting the cold motor on gasoline before the naphtaline could be switched in. It could be done after 13 minutes 37 seconds, although at that moment the naphtaline in the receptacle was not yet all melted. After a stop of 10 minutes, the motor could be restarted on naphtaline without difficulty, while after another stop lasting 16 minutes an injection of gasoline in the cylinders was required to help out.

The figures, as given above, bring the cost of operating a taxicab on naphtaline over 100 kilometers, at the speed mentioned, to 0.85 franc, and if the cost of the gasoline necessary for starting is counted, the total fuel cost for 100 kilometers barely reaches 1 franc. With gasoline alone, 10 liters would be consumed, costing 5 francs.

The weight of the motor, carbureter and melting apparatus did not reach 10 kilograms per horsepower.

The annual production of naphtaline in France amounts at present to 30,000 tons, while Germany produces 175,000 tons, England 126,000 tons and Belgium 1,200 tons. The price varies according to the purity of the product and the transportation cost, ranging from 5 francs for 100 kilograms at Antwerp to 14.75 francs for German naphtaline delivered in Paris. Until recently the marketing of crude naphtaline has been extremely difficult, and the production was therefore restricted as much as consistent with the rectification of the coal oils and tars of which it is the by-product. The moment the tar distillers gain a ready market for their naphtaline, this condition will be changed, since it will be to their interest to produce as much as possible, thereby also improving the grade of their main output. Besides, a larger market is likely to be created for the tars, as soon as they can be made more economically. These things going hand in hand, it is then probable that naphtaline can be produced in much greater quantity than is now the case, and that it will rise to a considerable importance as a motor fuel, especially for heavy hauling.—From *Le Poids Lourd,* May 10.

BALLET'S Removable Wire Wheel.—A simple construction serving the purpose of having a wire wheel substantially secured to and yet easily removed from the fixed ball-bearing hub which remains mounted on the axle-end, is shown in Fig. 2. It is designed by Ballet, and the mechanism, like that of some other demountable French wire wheels, seems inspired by gun mechanism. The fixed hub A has a semi-circular projection *a* against which abuts a similar projecting flange *b* on the demountable hub B, when the latter is pushed home against the short and steep cone on A by means of which the centering of the wheel is secured. The two projecting rims secure the rotation. The wheel is secured from coming off by the nut C, whose interior thread is interrupted like that of a screw tap. This is pushed onto the end of the fixed hub which is correspondingly formed, and a short turn then engages all of the threads of the two parts, blocking the demountable hub laterally. A spring clip engaging ratchet teeth in the face edge of the fixed hub obviates rotation of nut C. The cap D protects this clip. T is the brake drum, forming part of the fixed hub.—From *Omnia,* May 10.

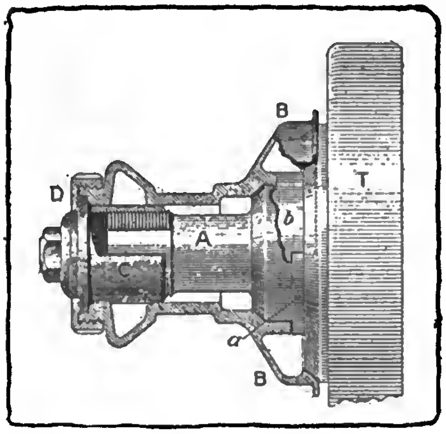

Fig. 2—Ballet's demountable wire wheel hub

—

METALLIZED Textiles.—The balloon cloths covered with a thin aluminum film on one side which have recently been placed in the market are suggested as possibly of interest to manufacturers of automobile tops, as they reflect sunlight strongly, including the ultraviolet rays, and therefore tend to keep the space directly under the top cool—a feature which adds considerably to the comfort of passengers, even if the sides of the vehicle are open and particularly if the top is low and the climate tropical. The aluminum is blown upon the rubberized cloth in the form of dust when the cloth comes from the spreading-machine and while the rubber with which it is impregnated is still soft. Aluminum dust is not powdery, though it appears so, but is in reality composed of infinitely small scales, and these stick to the rubber at once and are afterwards rolled into it on the calendering machine, forming a perfectly smooth surface which sheds water quickly and, as said, reflects light rays and heat radiations. It is the last-mentioned property which makes this cloth indispensable for balloons, in view of the need of avoiding all sudden expansion of the gases which they contain, but the protection which the metal coating affords against rapid oxidation of the rubber by the sun's rays is also a matter of primary importance, meaning a much increased durability for a purpose requiring lasting gas-tightness.—From *Kunststoffe,* May 1.

Contemporary Articles on Subjects Allied to Automobiles But Not Adapted for Abbreviation

Revue de Métallurgie for May contains a symposium of articles intended as a survey of present knowledge relating to the modifications of the properties of metals, especially steel, which are produced by mechanical working processes—as distinguished from heat-treatment—and are neutralized by annealing. One of the articles is a translation of the essay by Goerens submitted to the Iron and Steel Institute in 1911 for the Carnegie Research Scholarship. The others are by M. P. Galy-Ache on Upsetting (*écrouissage*), by M. Hanriot on the same subject and by Léon Guillet on Annealing of Upset Metal.

In *Automobil-Rundschau* for April 30 there is reproduced a paper by Dr.-Ing. Carl Büchner on the benzol question with special reference to carbureter construction. It dwells on the chemical composition of different fuels and their ignitability, on the movements of gases under different methods of throttling and on preheating of air and fuel. Illustrated. To be continued.

In *Internal Combustion Engineering* of May 14 G. H. Baillie discusses automobile spring design with illustrations of car and axle movements. He proposes to measure the jerk given by a road obstacle by means of the amount of change in the acceleration of the car produced in a finite time. The question of fitting variable loads is not taken up.

In *Der Motorwagen* of April 30 Engineer August Bauschlicher discusses fuels for explosion motors, their sources and their thermo-dynamic properties.

In *La Technique Automobile et Aérienne* for April 15 G. Lienhard analyses the movements and stresses occurring in the motor with variable stroke which was exhibited by the Itala company at the last Paris show. The variable stroke supplants the customary change-gear. The principle of the construction was described in these columns in the issue of January 4, 1912.

In the same journal an essay by Pol Ravigneaux on the reactions of transmission shafts upon their supports and an instalment of a serial by the same author upon the kinetics involved in a vehicle's capacity for "holding the road"; mathematical and relating largely to spring suspensions and tires.

The Engineers' Forum

Making More Tests in Less Space

Suggested Arrangement Gives Maximum Capacity at Least Cost

CHICAGO, ILL.—Editor THE AUTOMOBILE.—The test of the gasoline motor and its correlated parts prior to its trials upon the road is entirely taken care of by the laboratory block test. Here the assembled motor is given every conceivable load at the different speeds to bring out its characteristics. The conditions existent in the majority of automobile plants tend to sacrifice scientific accuracy and thoroughness for want of time and facilities. With a single block test equipment the allotted time for laboratory tests will not be proportionate to the number of tests and models. On the contrary, this time will be so diminished that the tests will be of an indicative nature rather than scientific proof.

The capacity may, of course, be doubled or tripled by simply multiplying the single complete testing unit, usually consisting of a bed plate for the gasoline motor and some form of dynamometer. By thus increasing capacity the time difficulty is removed and with it in consequence every opportunity is allowed for scientific thoroughness. The great objection to this means of increasing capacity is the cost.

The duty of the engineer is to find the maximum equipment purchased by the fixed allowance granted. The dynamometer represents the greatest expense when multiplying units to increase capacity. As the approved type of dynamometer is electric this expense is considerable. Not only this, but the calibration and standardizing of several dynamometers would never equal the accuracy of one common dynamometer.

The accompanying drawings represent a very compact and inexpensive means of meeting these conditions. An electric dynamometer is used common to all the bed plates upon which motors, gearsets, rear axles, etc., may be mounted for test. Thus the expense of multiplying capacity is proportional to the slight cost of adding additional bed plates and a special base for dynamometer. A still further advantage lies in the ability to use the dynamometer to absorb the power on the rear wheels of a chassis.

Fig. 1 is a side elevation of one cast iron bed plate and an electric dynamometer of conventional design. Beneath the regular stock base furnished with the dynamometer is a special subbase designed with a machined surface on which to move the dynamometer about a fixed center. The subbase should be "let in" to the flooring to keep the horizontal axis of the armature as low as possible.

Fig. 2 represents the layout of the floor plan showing the relative position of dynamometer to three bed plates A, B and C. The center lines of A, B and C are radii from the pivotal center of dynamometer base. These radii are spaced at an angle of 45° for convenience, as will be shown later, and marked on the face of each base. Thus, should a test be in progress on A, a motor may be perfectly lined with the radius of B and raised to the proper height. As soon as test on A is completed or stopped for alterations it is simply necessary to move dynamometer on its pivotal center 45° when B would be ready for test, etc. For convenience the subbase of the dynamometer is drilled for tapered dowel-pins for each position in which it may be used. As the dynamometer base proper is a square the drilled positions for A and C are the same provided the holes are drilled in corners of a square. The pins should be of sufficient taper and diameter to facilitate an approximate alignment, the driving of the pins, making the exact location always the same. When located, cap screws threaded into the subbase hold the apparatus rigidly.

If desirable the pivotal center may have a centering pin to not only keep the dynamometer centrally located, but also act as a jack with which to take the weight off the base. To do this the pin is threaded into the dynamometer base proper and has a tapered seat in the center of the subbase. However, this has not been found necessary up to 100 horsepower outfits.

The flexible cables carrying the current must have plenty of slack and be secured to the stationary frame of the dynamometer. This prevents any deflection of the scale arm outside of that due to actual power developed.

All measuring instruments reading the results of the dynamometer must likewise be connected to the movable base. Thus tachometer, revolution counter and scales will not change their relative positions with the dynamometer itself.

For testing the complete chassis the dynamometer is located as at A and suitable pulleys placed on both ends of the armature shaft. The car may then be backed into position on extended radius C. At the same time such a test will not interfere with other work set up on the various blocks.

The advantages of this system are: 1—Minimum expenditure with maximum capacity; 2—least floor space commensurate with accessibility; 3—absolute standard for measuring power common to all tests; 4—low first cost which enables the small manufacturer to have the same equipment as the largest; and 5—an expanding system which may be added to at any time.—R. M. ANDERSON, Stromberg Motor Devices Co.

Runabout Body Design for Paige-Detroit

Spare Tires Carried in Concealed Storage Space at Rear—Body Doors Oppositely Hinged for Ventilation of Interior

By George J. Mercer

THERE are three conspicuous essentials to consider in body designing today. These are: First, the proportioning of the body so that the comfort of the passengers is well provided for; second, the elimination as far as possible of flat external surface that would result in loss of power against the wind; and third, the provision of adequate storage space for extra parts being carried on the car.

The first two of these essentials has received careful consideration at the hands of the designers and the results are used as talking points of considerable weight by automobile salesmen. With regard to the third consideration, the provision of storage space, however, this does not seem to have been given the attention that the subject apparently deserves. Even when the space is ample the important feature of accessibility is often ignored or insufficiently considered.

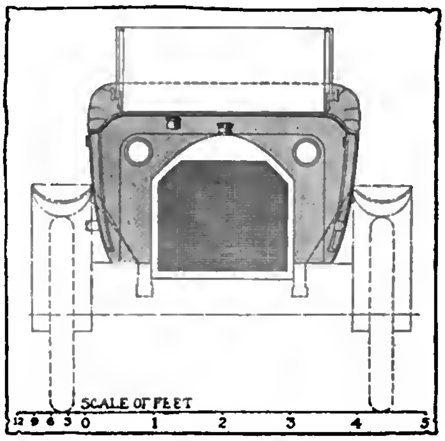

Fig. 1—Front view, showing position of gasoline filler in top of dash cowl

One matter that is receiving more attention than formerly is the disposal of the spare tires, though there is still much to be desired in the way these articles are cared for. The storage of tires inside the body has not met with the favor that it was anticipated would be the case.

A runabout body design with an interior compartment for the tires is the subject of this article, and the body is shown mounted on the medium-sized Paige-Detroit chassis, having left-side drive, 116-inch wheelbase, 34 by 4-inch tires, body space back of the dash of approximately 91.5 inches and a rating of 36 horsepower.

This car is especially adapted for rear storage, as the gasoline tank is provided for at the front. This tank, of approximately 14-gallon capacity, is standard equipment and is indicated by dotted lines in Fig. 2.

Taking the rear compartment first, this is long enough to take nicely the two tires that are considered necessary spare equipment for touring. Since the gasoline tank is provided for in front under the hood, all the space at the rear is available for carrying the tires and for luggage. In this case, the tires being 34 inches in diameter it is an easy matter to provide sufficient space. At the rear is a door large enough for the entrance of the tires. This door is hinged at the top, and at the sides and along the bottom and is made watertight by having a flanged lip, that extends inward from the inside of the door. When closed this lip enters a recess packed with either rubber or felt. At the top the hinge is continuous and keeps out the water. Fasteners are placed at each of the lower corners and in the center a hasp and padlock is fitted.

The tires are set on a tray that slides on rollers. To remove the tires, the door is first held open in the upright position, and the tray rolled out as indicated by dotted lines on Fig. 2. At the back end a hinged leg, forming part of the tray equipment, is dropped down for a support, while at the front the tray rests on the slider. The inside space of the tires is utilized by a drum that serves the double purpose of keeping the tires in position on the tray and also acting as luggage space for small articles. At each rear corner of the tray is a small triangular box that can be used for small tools. This box thus utilizes the space at the corners not occupied by the tires. Its shape and position is indicated on the plan view, Fig. 3.

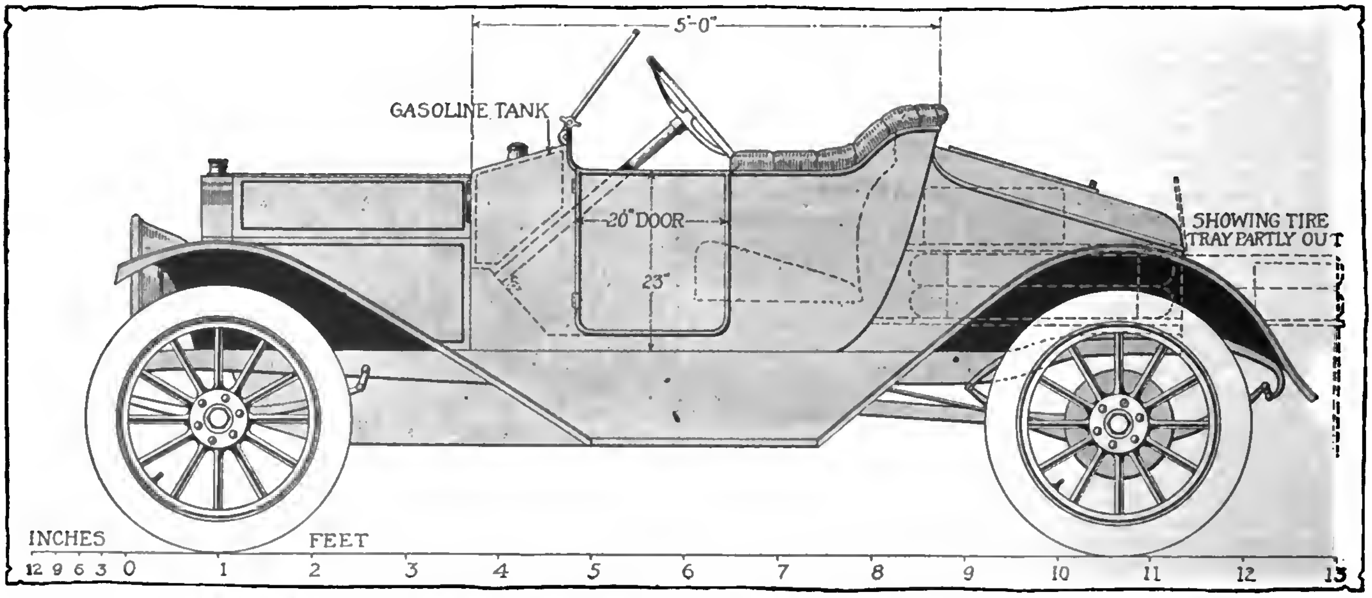

Fig. 2—Side elevation to scale of suggested runabout design adapted to chassis of Paige-Detroit 36

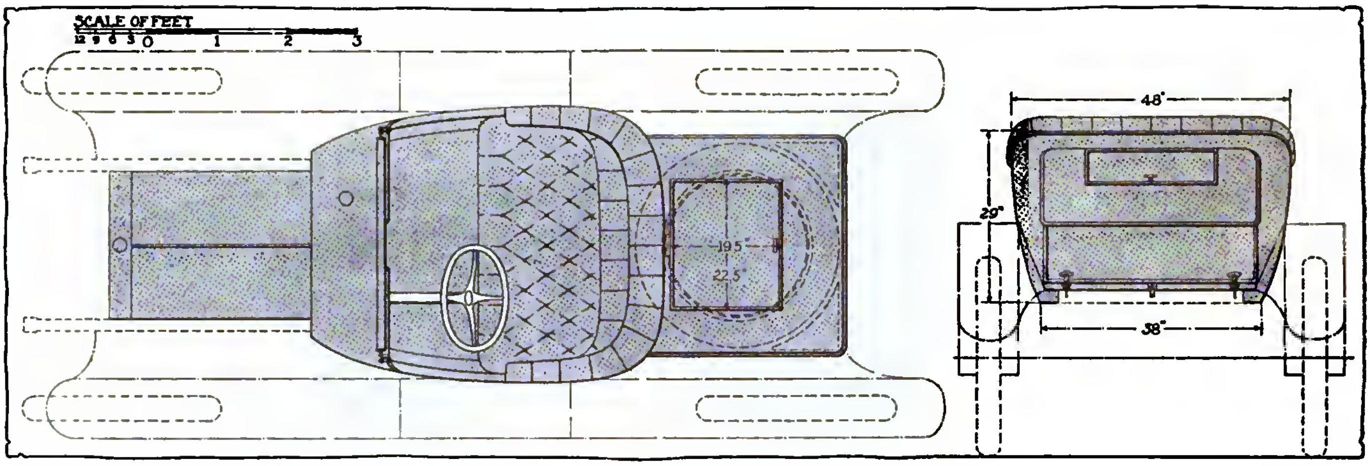


Plan view and rear elevation of suggested runabout body for Paige-Detroit chassis

Above the tire compartment the space is utilized for carrying miscellaneous articles of luggage. This is sufficient for one large or two small suit cases and have room besides. The floor dividing the upper and lower compartments is one sheet of metal and waterproof and there is suitable drainage, so that in case of water leaking into the top compartment it will not be carried into the lower compartment and do damage. An idea of the storage space that this upper compartment provides can be obtained by reference to the side elevation Fig. 2 in which a suit case 18 inches by 8 inches by 30 inches is indicated. The door on top is made watertight.

The body interior has ample seating space for two people. A generous thickness is allowed for in the trimming, and there is a small locker space under the seat. The gasoline tank under the cowl is not directly connected with the metal of the body; air space is allowed all around. The filling plug is directly under the cap on the cowl.

The electric dash lamps are placed flush with the dash and the horn is placed under the hood.

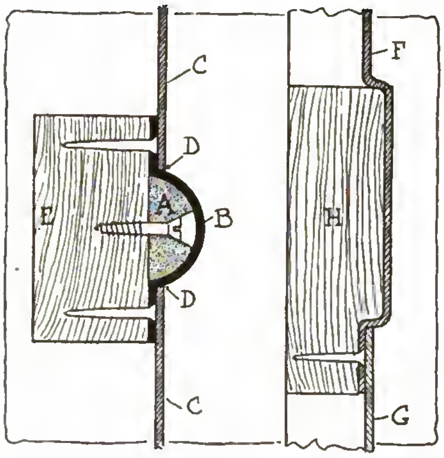
One of the novelties used on this design is the Auster windshield. This shield is of canvas that is unrolled from a spring roller and held in position by the two side arms as shown on Fig. 2. On Fig. 3 the shield is shown folded and the arms are turned down. When in use the angle of the shield can be made at will and as the material is very light it can be folded away very easily. This type of shield has most of the advantages of the glass shield without its greater weight.

The ventilation of the body is by means of the doors entirely, that on the left side being hinged opposite to the right door. By leaving both doors slightly open and as the openings are in opposite direction a cross circulation of air is obtained.

The standard equipment is utilized throughout, including the front and rear fenders. The color specification for this design cannot be improved over that of the stock car. Standard blue and striping and black leather are as good and lasting in results as can be desired. The quality of the material should be of the best for hair, springs and leather if comfort is to be had after the car has seen service.

New Metalklad System of Metal Body Construction

THE increasing use of sheet metal as a material for the panels is one of the most noticeable tendencies in automobile body construction at the present time. Metal lends itself readily to the formation of harmonious curves which enhance the appearance of the car. And the close attention which is being given to this point besides the great favor which the streamline type of body is meeting with are undoubtedly having a stimulating effect on those body builders who heretofore have devoted their energies chiefly to construction in wood. As is well known, the two metals used in body work are steel and aluminum, and the method of joining the separate sheets is a constructional detail that admits of much ingenuity in the design so that the resulting exterior surface is smooth and unbroken.



Figs. 1 and 2—Methods of joining panels in metal body construction

One method of accomplishing this result adopted by an English concern, the Regent Carriage Co., of London, is described in *The Autocar*, London. The system is known as the Metalklad system, in which a strong but light ash framing is covered with steel panels which are pinned and soldered so that they give the appearance of a jointless construction.

The method in which this is effected is shown in the diagrams, Figs. 1 and 2, the former showing how two adjacent panel sheets are joined up on either side of an aluminum moulding A. This moulding is, first of all, secured to one of the wood frame members E, and is then covered with a strip of sheet steel B, which is pinned down by small iron nails. The panel sheets C are then brought up to position and are also closely pinned, the holes being countersunk so that the pin heads are, if anything, below the surface. The two joints D are then carefully soldered and the solder is run over the pin heads, the whole being afterwards cleaned off with sandpaper. It is found that the solder finds its way well in between the panels and the strip B and makes a thoroughly secure joint, which, at the same time, is not apparent as a joint. Fig. 2 shows how, in a similar manner, the upper panel sheet is beaten out and secured.

The method of construction seems admirable and should entirely eliminate the hardening and showing up of joints.

Fig. 1—View of the country where the Easton, Conn., pipe line is being laid, showing truck and some pipes on the road

Trucks Save 86.6 Per Cent. In Heavy Work

In Constructing Pipe Line, Automobiles Transport a Pipe for $2 When By Horse It Costs $15

GIVEN: The problem to build a dam and a drinking-water pipe line over a distance of about 7 miles of hilly territory and containing mostly poor roads; the solution to be reached at the lowest possible cost. This problem means transportation at minimum cost of iron pipes weighing several tons, of thousands of hundredweight bags full of cement, of machinery, power plants, timber, telpherage, coal, etc., aggregating hundreds or thousands of tons. And of these tons, each pound and ounce must be carried over the poor roads, up steep hills, in the shortest possible time. If these facts are kept in mind, the vastness of the problem becomes apparent even to those not familiar with such work.

That motor trucks are capable of considerably assisting the contractor and engineer in such work, needs hardly to be said; but that it was ever possible to do such pieces of work without the help of trucks is a thing to be wondered at. Only concise comparison, however, brings out the marvelous advantage of the commercial motor vehicle.

First a general statement as to the comparative cost: **To build the pipe line of about 7 miles length, approximately 1,300 pipes of 5 feet diameter and roughly 10 yards length are needed. Each of these cast-iron pipes weighs 5 tons, and to transport it over the distance of about 5 miles**—if this is taken as the average travel of each pipe, on account of the hilly condition of the territory and to compensate for the hills between the loading point and half way from the end of the line—**costs $3 a ton or $15 per pipe, if horses are used for the work. If motor trucks are used, the cost is $2 per pipe or 86.6 per cent. less. The total saving on a line of 1,300 pipes is $16,900.** A similar saving as compared with the cost of horse transportation applies in the case of machinery, building material and so forth.

The Bridgeport Hydraulic Co., of Bridgeport, Conn., is

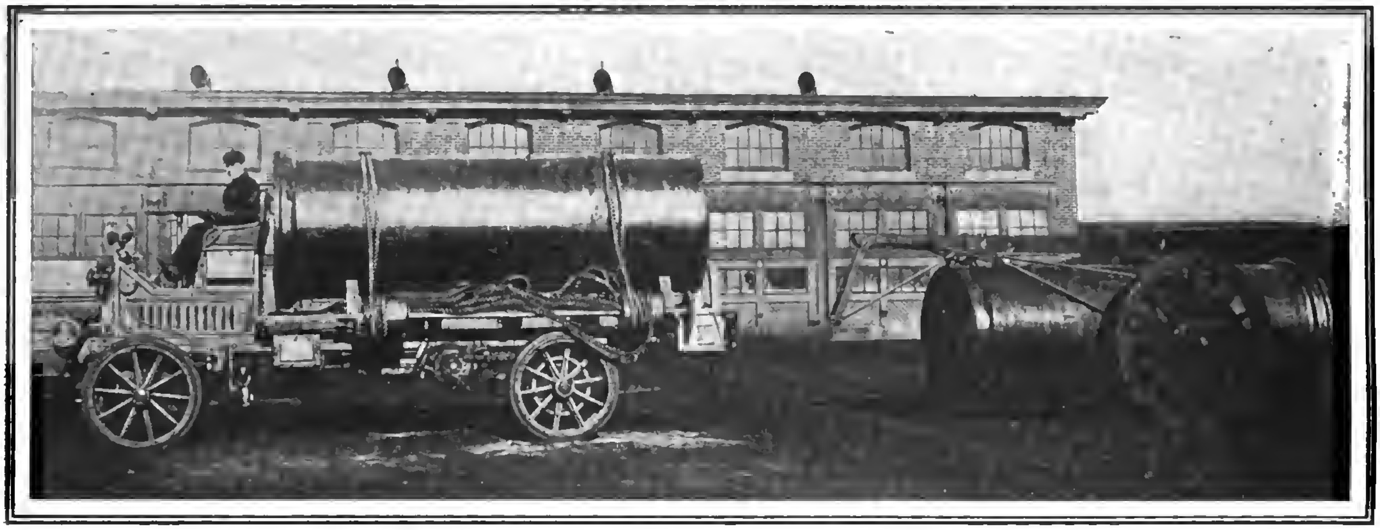

Fig. 2—Truck and trailer loaded ready for the way. Observe the hoisting mechanism on the platform of the truck

carrying out the work referred to in the opening lines, using for this purpose freight automobiles. Two of these are Locomobiles, of the 5-ton type, capable of carrying that and also of hauling an equal load resting on a trailer connected to the truck proper. Fig. 1 shows one of these trucks traveling along the road, and Fig. 2 shows it loaded and connected with a loaded trailer, ready for work. The trucks used for this work are built with a transmission permitting of using the motor power for work other than propelling the truck, and Fig. 2 illustrates the machinery which permits of applying it to the loading and unloading of the truck with the 5-ton pipes. This device consists of a pair of drums or capstans mounted on a horizontal shaft at the left side of the truck platform and driven by shafting from the working shaft of the special gearset. The operation of the drums is regulated by a lever mounted just behind the speed-change lever. In front and behind each of the front and rear drums, respectively, a cross-bar is mounted on the truck, being secured to the body platform and being fitted with a pair of blocks forming a seat, shaped to accommodate the curvature of the pipe.

Fig. 4 shows the method of leading, the pipe being drawn up over the power-operated capstan drums by means of two strong ropes. In unloading, the ropes are slackened around the drums, so that the pipe is sunk by its own weight. Two blocks of wood and a pair of pressed-steel channels form the runway for the pipe. To take the weight of the pipe off the truck springs when the pipe is positioned on one side of the

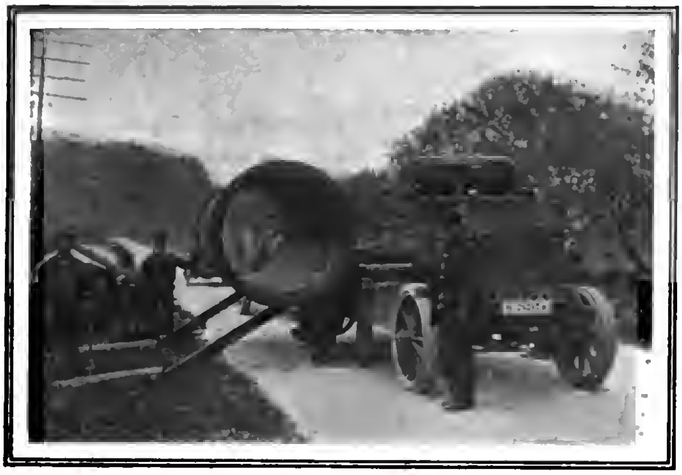

Fig. 4—Unloading the Locomobile pipe truck

Fig. 5—Unloading the trailer of the truck

chassis, a pair of jacks mounted under the frame on this side are used. The jacks proper are secured to tree stumps.

The trailer consists of a pair of wheels mounted on a steel axle curved overhead, to the middle of which a crane-neck beam is secured. The long end of this beam is trussed to the axle at four places so as to constitute a rigid system. At the short end of the beam, just above the axle, is a ratchet device with two pawls and a long lever. By working these a chain laid around the pipe is either wound around or off the ratchet wheel, thereby raising or lowering the pipe. One man controls the pawls, keeping one in and the other out of engagement with the ratchet, while two men control the end of the lever bar to which a cable is fastened.

All pipes are loaded at a dock where they are brought by a steamer. They are discharged along the roadside. Machinery and other loads are also loaded either by motor power or by means of cranes. Cement and similar material is placed on the truck in bags, being put on and off while the truck runs up against a platform which is on one level with that of the truck body, as shown in Fig. 3.

Provided each truck is used in conjunction with a trailer, it can transport seven pipes per average day, making three trips and loading for another on the next day, and making four trips on that day. As the total daily average operation cost of one of the trucks is $12.26 and that of the other $14, the latter figure may be safely taken as an average daily cost, and figuring fourteen pipes in 2 days at the cost of $28, or $2 a pipe, as stated above.

The tabulations at the bottom of this and the next page show the various expenses of both Locomobile trucks, each for the first 9 months after installation. During this time the total cost of operation and maintenance for trucks No. 2 and 3 were $3,198.02 and $2,379.03, respectively. The average cost per ton carried was 77.9 cents and 67.3 cents respectively. The various average figures appearing in this tabulation will probably be of interest to users of trucks. The tabulation showing the cost of truck No. 2 gives, under the heading remarks bonuses, premiums pair to drivers for extra trips made; a driver being paid $1.00 for each trip made in addition over the seven prescribed for 2 days.

On the bottom of page 22 some figures are given which give an idea of the time spent in loading, carrying and unloading the pipes on the job here illustrated. On May 21, the truck traveled 5.6 miles in 35 minutes, at 9.6 miles an hour. Having arrived at the point of unloading, the skids, etc., were gotten ready for unloading, the pipes were unloaded and the truck was made ready to leave, starting away from the place of unloading 9 minutes after having arrived there. It traveled to West End, 4.6 miles distant, at a speed of 9.2 miles an hour. In the afternoon, the truck arrived at the dock at 1:25 and during the next 39 minutes was loaded with a pipe and coupled to a trailer loaded likewise. It took 1 hour, 8 minutes for the truck and trailer to arrive at the point of unloadmg, where the teams spent 38 minutes in unloading the two pipes before starting back.

On the following day the truck upon arrival at the dock was loaded with a pipe and connected to trailer, all of which took 16.5 minutes. After losing 10 minutes on the road, the entire journey took 24 minutes, while unloading took 34 minutes, after which the truck started on its way back.

The men busy in loading and unloading were: One at each drum, the driver to operate the power and place the truck and the trailer and one man to guide the ropes and to superintend the whole work.

Records of Time Spent by 5-Ton Locomobile Truck Used in Building the Easton Line

Truck Without Trailer

May 21	Minutes
From dock to unloading point, 5.6 miles	35
Preparation to lower pipe	3.5
Lowering the pipe	1.5
Getting skids and jacks on truck, etc	4
Get ready to leave the place	.5
Travel to West End (North avenue, 4.6 miles)	30.5

Truck and Trailer

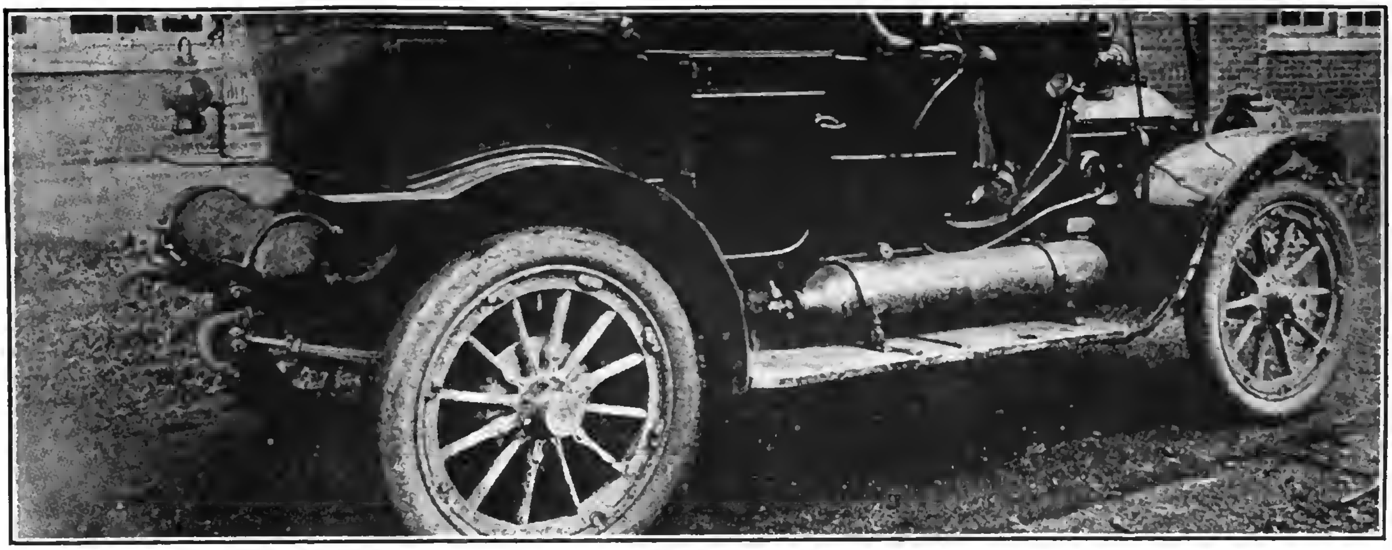
Afternoon: Preparing truck for loading at dock	7
Hoist pipe on to truck	3
Remove skids, jacks, etc., fastening ropes	2
Backing up to trailer and coupling it on	3
Time lost in waiting for coats, etc	24
Travel to unloading point, 5.6 miles	68
Preparations for unloading	7
Lowering the pipe carried on truck	1.5
Getting skids and rope on truck, etc	4
Lost time in inspecting a bridge over which a pipe will have to be transported on May 22*	7
Preparing to unload trailer	1.5
Unloading the trailer from its pipe	2
Pulling the trailer away from the pipe	5
Rolling the two pipes across the road	8.5
Preparing to leave the place	1.5
Travel back to dock, 5.6 miles	45

Truck and Trailer

May 22	Minutes
Preparing to load the truck	3
Load the pipe on to truck	4
Getting skids and jack on truck, etc	2
Backing up to trailer and coupling it on	4
Traveling to unloading point, 5.6 miles, including loss of 10 minutes on the road†	84
Preparing to unload the truck	7
Lowering the pipe carried on truck	3
Getting skids and rope on truck, etc	3
Lost time in getting out of a wagon's way	2
Pulling up the trailer before unloading it	.5
Unloading the trailer of its pipe	5
Pulling the trailer away from the pipe	1.5
Rolling the two pipes out of the way	7
Preparing to leave the place	3.5
Travel to dock, 5.6 miles	28

*As the pipes were unloaded near a feeble-looking wooden bridge, the driver thought it opportune to inspect the latter's strength. The time thus lost proved a good investment: the bridge would have been unable to support the truck and its load.

†In passing some of the pipe-line construction work, a rope was encountered, taut across the road, and the truck had to wait until the workers were ready to slacken it.



Packard car, showing mounting of the compression tanks containing the liquefied natural gas which is used as fuel

Automobile Run on Liquefied Natural Gas

Ford Car Runs 100 Miles on 300 Cubic Feet at a Cost of 1.5 Cents

CHICAGO, ILL, May 21.—To run motor cars on gas carried under pressure on the running board or some other accessible location instead of using gasoline is the prospect offered by a new process of liquefying natural gas. The economy of natural gas as a fuel for gasoline engines long has been recognized; in fact, this is the fuel employed for testing purposes in some of the motor car factories in Detroit. The difficulty has been in utilizing the gas in a power plant that is not stationary.

A system of compressing natural gas to a liquid and storing it in this form in tanks resembling those used for lighting acetylene lamps has recently been developed by Albert M. Schenk, president of the Packer's Motor Truck Co., Wheeling, W. Va. By his process, the natural gas as it comes from the wells is liquefied and stored under a pressure of 50 pounds per square inch in steel tanks. It is found that this liquefaction removes most of the impurities from the gas so that it emerges from the tank practically a pure fuel.

In application, the tank is simply connected with small expansion chamber to the ordinary carbureter and the fuel admitted to the engine and used in precisely the same way as gasoline is used. Several cars have been fitted with the tanks, among them, two trucks, one Packard touring car and a Ford.

At present the cost of liquefaction and storing is 5 cents per thousand cubic feet of free gas, and it is stated that in tests on the speedway at Indianapolis, Ind., the Ford car ran 100 miles on less than 300 cubic feet. Each tank as now arranged holds about 600 cubic feet of free gas at a pressure of 50 pounds, but it is expected to double the pressure and the mileage per tank under improved methods of manufacture.

In general, the expectation of the backers of the new process is to sell the liquefied gas at a price that will make the cost per mile one-half that of gasoline. It is expected to establish refilling stations throughout the country so that empty tanks may be exchanged for full ones in much the same way that lighting tanks are exchanged.

At the present time the regular carbureters are used, but experiments are under way toward dispensing with the carbureter. One of the claims made for the fuel is that it is clean, leaving no deposit and no smoke. Patents for the process have been granted and others are in the patent office for which reason no details of the process of manufacture can be given at this time.

Why Benzol is a Good Fuel

LONDON, ENGLAND, May 31—At a recent dinner given by Lord Montague, editor of *The Car*, Henry L. Doherty, of New York City, made the statement that no less than 12,000,000 gallons of benzol could be recovered annually from the city gas works of London alone by probably handling the gas. Experts in the gas business in New York claim that an adequate substitute for gasoline as an automobile fuel cannot be developed from this source in the United States. It has been pointed out that the introduction of benzol as an automobile fuel has made but little progress thus far, although present indications point to an increasing activity in the popularization of this substitute for gasoline.

Some reports from car owners who have tried benzol in their machines indicate that the refined benzol is superior to gasoline. The motor starts more readily on both the refined and crude benzol and seems to be much more resilient and to give more power than with gasoline. The refined, or water white, benzol is stated to be an excellent fuel for internal combustion engines, but the crude is not as good because it gums up the inlet valves and manifold. The crude material carries some matter in suspension and some in solution, say several cars owners who have given the subject intelligent attention, and this matter precipitates the moment the clear benzol is gasified or vaporized and some of it collects in the intake end.

The new fuel for automobiles, liquefied natural gas, burns freely in the air without danger of explosion

In which Letters from Readers Are Answered and Discussed

Owners Discuss Location of Gearbox

Coil Not Apt To Go Wrong—Wiring of Michigan Ignition—Pulverized Coal Recommended as a Cheap Fuel—Motor Chokes When Running at Low Speed

EDITOR THE AUTOMOBILE:—I have been reading with considerable interest, the articles about the proper location of the transmission. This is well enough for the engineers to discuss, but they deal with the problem of new cars. Why not invite some of the users to express their opinions? I believe the only test is after the car has been in use a year or two, and the man who has used all of the different kinds is best qualified to speak. I happened to have two cars with each kind of arrangement, and find the rear axle idea altogether wrong. In the first place they are hard to get at for repairs, oiling and adjustment. In the second place, owing to shocks sustained, they give trouble, after 5,000 miles, and will continue to do so. I find that arrangement is hard on tires too. My experience teaches me that for a heavy car, say 3,000 pounds or over, the amidship location is much to be preferred. For light cars, the unit with the motor does very well. The unit with rear axle has proved a complete failure on both of my cars, one of which was heavy, and the other fairly light.

Mina, So. Dak. C. E. BASHL.

—Do you agree with Mr. Bashl? Car owners who have views upon this subject are invited to express them in these columns. Under the heod of the Engineers' Forum, engineers are thoroughly threshing this matter out, now it remains for the car owner to speak his preference.

¶ *In answering this question car owners are directed to the fact that one of the leading arguments advanced against rear axle location is that of increased axle weight and consequent tire damage. Definite information on this line would be in order.*

¶ *Those not in favor of the amidship location have urged against it lack of accessibility.*

¶ *The gearbox os a unit with the motor has been criticised in that it is not suitable for a heavyweight car because of the fact that too much weight is placed in front.*

Coil Does Not Require Much Care

EDITOR THE AUTOMOBILE:—I have had considerable trouble with the ignition on my car this spring which was finally traced by a repair man to a defective coil. The motor would run on battery but would not run on magneto. The system in use is a Splitdorf model N magneto and model N coil. I have sent for a new coil. Can you suggest what may have caused the coil to give out, so that I may avoid trouble as far as possible in the future? The motor does not start as readily as the average and I would like to inquire if it will do any harm to use six or eight cells for starting, instead of the usual battery of four as at present installed? I have used four different sets, but they all required too much cranking, even in warm weather. The wiring from the battery runs through the coil box. While running on the battery, since the failure of the magneto, turning on too much gasoline, or advancing spark too far, seems to cause motor to skip or misfire.

Farmington, Conn. G. E. M.

—Trouble will not develop in a coil very often and it is only occasionally that a defective one slips through the manufacturers' inspection departments and starts to cause trouble. One of the chief causes of coil trouble, and the fault of the car owner, is the use of too high a voltage. This generally causes a pitting of the vibrator points and tends to make them burn away rapidly. The use of four cells would never harm the coil. It would be better to use five cells as long as you are having trouble in starting and thus secure a hotter spark. Six cells are the limit in number, however. Each cell develops about 1 1-4 volts when new but this drops to a volt after they have been in use for some time.

Michigan Ignition on Regal Cars

Editor THE AUTOMOBILE:—We have a 1911 Regal 30 equipped with Michigan magneto and non-vibrating coil under hood with battery for starting. We bought the car which appeared to be in good shape, had no occasion to use it for several days and then it would not start on either magneto or battery and we could not get a spark from either. We took coil and magneto off and showed them to the K. C. Battery people. They told us the magneto was all right but the coil was wrong, and they worked on it. Since getting it back we have been unable to get the engine to run on magneto and only rather poorly on battery. It sounds much like the trouble we had with a Splitdorf coil as published in THE AUTOMOBILE recently. Howevere, the wiring is more complicated when under the hood as in this case. Kindly show a wiring diagram of this.

2—The Moline engine is given 4.125 bore and 6-inch stroke, rated 40 horsepower. The Henderson a bore of 4.12 stroke by 5.5 stroke claimed to have actually 44 horsepower. Where does it come in?

3—Is it an advantage or a disadvantage to have clutch and brake connected?

Bosworth, Mo. BOSWORTH GARAGE.

—1—The trouble with the ignition system is probably in the coil rather than in wiring. The wiring diagram is published herewith, Fig. 1, however, in case you may need it for your guidance. In a case of this kind it is not wise to attempt the repair of the coil yourself, either from a standpoint of securing better work or for economy. The coil should be sent to the maker who will give you the best service at the lowest rate.

2—Both of these motors will readily develop the power at which they are rated when new. The maker's rating is not of any particular value in most instances and is merely used as a method of naming the model. The makers very often will change the apparent rating of a model in putting the same motor in a different chassis. For instance, a car which is called a 40 this season may next be known as a 44 while all the essential features of the motor are the same.

3—This is a matter of personal choice. The advantage of having the clutch and brake operated from the same pedal is that one pedal is eliminated. It is not necessary to remove the foot from the pedal in stopping the car by simply pressing on the pedal and there is no chance to stall the motor by accidentally applying the brake with the clutch engaged. The disadvantages are that it is sometimes difficult to tell when the clutch is just disengaged before the brake is on. It is quicker to press the two pedals at the same time than to press the single pedal through double the distance. It is sometimes necessary in severe work to use the brakes as well as the motor for a brake. This could not be done with the single pedal.

Perhaps you refer to the practice which is followed by many manufacturers of connecting the emergency brake lever with the clutch so that when the emergency brake is applied the clutch is thrown out of engagement at the same time. This is largely a matter of personal preference, most car owners having cars equipped with this arrangement being highly satisfied with it while others do not like it. One of the chief objections to it is that it prevents the use of the motor as a brake when the emergency brake is being used and vice versa. It has the pronounced advantage of adding to the safety factor for the car cannot be started when the emergency brake is on.

Pulverized Coal as a Cheap Fuel

Editor The Automobile:—I have been much interested in the attempts to solve the problem of high-priced fuels. It seems to me that there are yet vast possibilities in the use of coal, especially powdered coal.

I have just re-read with considerable interest the article entitled, "Pulverized Coal a New Fuel," by Prof. William D. Ennis, which appeared in The Automobile for October 12, 1911.

I should like to ask the following questions which the article by Professor Ennis has brought to my mind:

1—Can any kind of hard or soft coal be used when powdered? If not, why not?

2—What is meant by 60 or 80 mesh?

3—The tube mill is mentioned as one of the types which are used to pulverize the coal. How is it constructed?

4—The following statement is made: "A highly volatile soft coal must be employed." Why? Laying aside the difference in cost, why cannot hard coal be used? Are there any pamphlets or books devoted to this subject? Where can I get information concerning types of grinding mills, methods of feeding the powdered coal, etc.?

5—In The Automobile, issue of May 1, 1913, there appears an article entitled, "Flameless Combustion and Automobiles of the Future." Chamot is mentioned as a granular fireproof material. What is it?

6—When using the liquid fuel in this system, is the air preheated or does it go to the burner at atmospheric temperature?

South Auburn, Ind. G. W. R.

—1—Only the soft coals can be used, because they contain the necessary percentage of volatile matter. Experiments have been made with the harder coals, but they have simply burned up in the furnace without producing the necessary gas. Only the softest grades of bituminous coal are satisfactory, because they contain the volatile matter necessary.

2—The mesh refers to the size of the screen through which the coal is sifted, and 60 and 80 are merely specific sizes.

3—The tube mill consists of a large cylinder about 8 feet in diameter and 20 feet long. In this cylinder there are thirty or forty pieces of iron pipe running the full length of the big cylinder. When the big cylinder is rotated rapidly the coal works its way between the pipes contained therein and is broken to pieces.

4—A highly volatile fuel must be employed in order that the gas be given off. Hard coal does not contain these gases. The only books extant on these subjects are in the form of transactions of the Brooklyn Engineers' Club of 4 years ago and some articles on the subject by Professor Ennis which were published in the *Engineering Magazine* about 6 years ago.

5—Chamot is a mixture of fireclay and burnt clay. This is the trade name given this particular combination of materials and its particular property is the fact that it is of exceedingly high fire test and hence valuable in the construction of crucibles, etc.

6—Either method can be used. Preheating the air results in a gain of efficiency.

Voltage at the Spark Gap

Editor The Automobile:—Could you tell me to what voltage the ordinary low-tension coil steps up the current, the current supply being six ordinary dry cells or Edison wet cells? The coil I refer to is the type ordinarily used with make-and-break ignition. Also, would it be practical to start engines with make-and-break ignition from a storage battery of 28 volts, fourteen cells, 40 ampere hours, without the use of a low-tension coil? Is this voltage too low? Would it injure the battery if used without a coil? Engines are six-cylinder, 6 by 8, running at 350 revolutions per minute, and are equipped with magnetos for running. The battery is used only for starting. This battery is installed for lighting but is seldom used and I thought I could save the cost of battery renewals for the engine if I used the storage battery without the coil if the voltage was high enough which I do not think it is. Of course I want to use all of the battery of fourteen cells or none of it, not taking three cells and using the coil, because this would be using the battery unevenly.

Scarsdale, N. Y. E. Hughes.

—The ordinary primary coil used with the make-and-break system of ignition will give a voltage at the sparking point of between 2,000 and 3,000 when used in conjunction with a 6-volt battery circuit. There are really two sparks at the points of such a system when considered carefully, one due to the breaking of the primary circuit by the separation of the points and the other is the induced current which passes through the windings when the primary circuit is broken. The separation of the points connected in the primary circuit really draws an electric arc and would in itself cause a small, weak spark to occur. When the current of the battery is broken, however, the phenome-

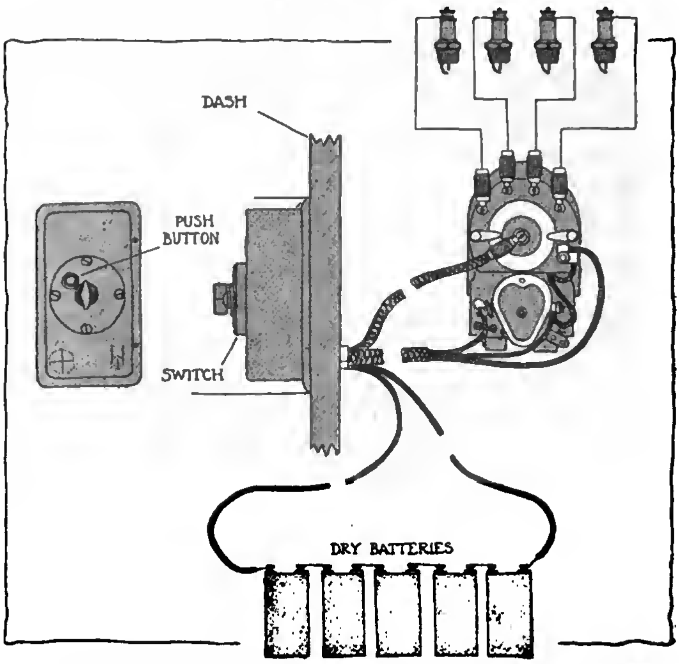

Fig. 1—Wiring diagram of Michigan ignition as used on the Regal

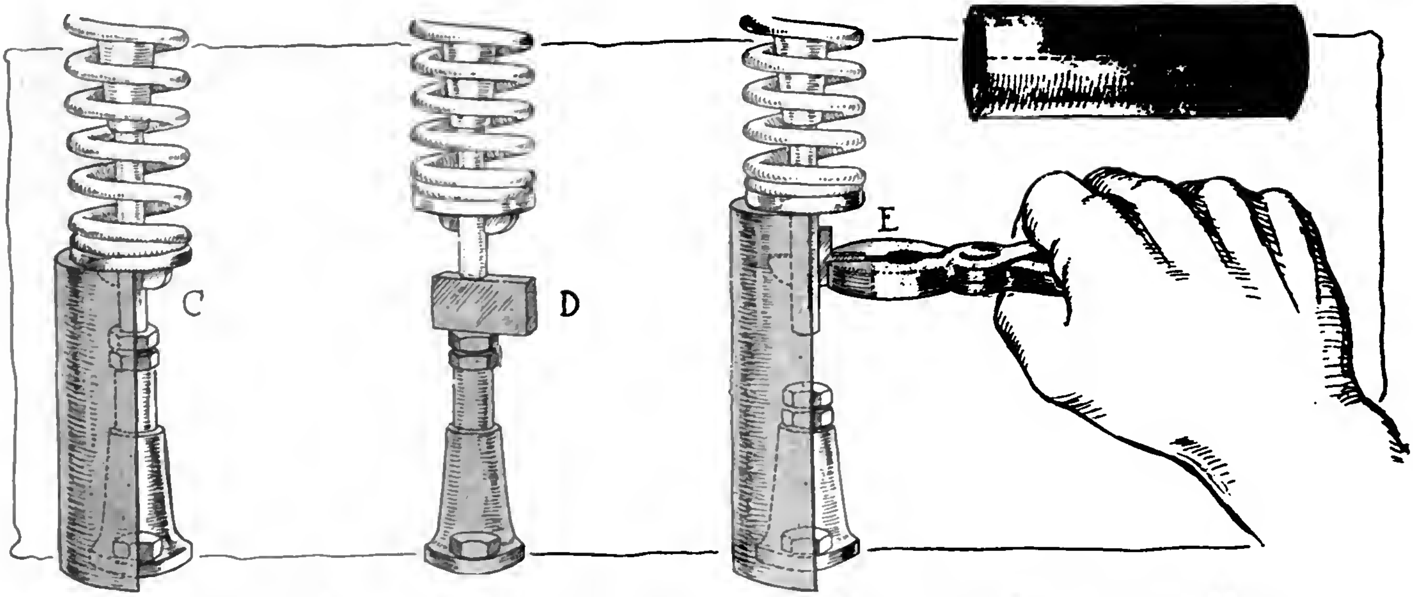

Fig. 2—Home-made valve lifter, pipe cut through A and B to correct length to fulfill steps C and D in lifting valve

non of electric induction occurs. A current of low amperage but of exceedingly high voltage, flowing in the opposite direction, causes the spark to be given the tension necessary to make it hot enough for ignition purposes.

It would not be practical to use your storage battery for the make-and-break ignition without a coil. In the first place, the current is not high enough in voltage to give a sufficiently hot spark and in the second place, to short-circuit the battery at each making of contact would soon put it out of commission altogether.

Another reason why it would not be good practice to use the battery without any coil would be the fact that the points on the coil would soon burn out. The trembler on the coil is designed for the low voltage and if a voltage four times as large were used the trembler points would not stand it even though frequently adjusted.

It would be a perfectly reasonable arrangement to connect the cells of your battery as follows: Take three out for ignition in connection with the coil. The remaining four could be used for lighting on a six-volt lighting circuit. It would be wise for you to connect one of the lighting cells in parallel so that you would not get an excess voltage at the lamps.

Standardizing Truck Tire Sizes

Editor The Automobile:—On pleasure cars, the same size tires are used for vehicles of the same weight. Why does not the same rule follow for trucks? Is there any progress being made for standardizing the tires to be used on trucks of the same carrying capacities? I believe that there is considerable difference now existing, especially in the heavier varieties of commercial cars. Is this not so?

Boston, Mass. Delivery.

—The tire question has progressed considerably the last year, and now seems to be following definite courses. For example, the pneumatic tire is in more general use for vehicles of under 1-ton capacity. The single pneumatics front and rear are the rule. These vehicles are generally intended for speeds of 15 miles per hour or over and in some of them the pneumatic equipment permits of setting the governor to operate at speeds from 20 to 25 miles per hour.

On the larger trucks dual rear tires are general, and the field is divided between the block and plain types with the cushion type occupying the position already mentioned.

There is still wide disparity in the tire equipments of trucks of the same load capacity, and it is apparent that either one maker is grossly undertiring his machine or the other maker overtiring. The position of the motor and the amount of body overhang back of the rear axle are factors which determine tire equipment, but when these are taken into consideration there still remains much variation. The following tabulation shows some examples:

Example	Motor location	Front tires	Rear tires
		One-Ton Vehicle.	
1	Hood	34 by 4½	36 by 3½
2	Hood	35 by 4½	35 by 4½
3	Hood	35 by 5	35 by 5
		Two-Ton Vehicles	
1	Hood	36 by 3½	34 by 4 dual
2	Hood	36 by 4	36 by 4 dual
3	Hood	36 by 4	36 by 3½ dual
4	Hood	36 by 4	36 by 3½ dual
5	Hood	34 by 4	36 by 3½ dual
6	Hood	34 by 3½	35 by 4 dual
		Three-Ton Vehicles	
1	Hood	36 by 5	42 by 5 single
2	Hood	38 by 5	42 by 5 dual
3	Hood	36 by 4	35 by 4 dual
4	Hood	36 by 5	40 by 5 dual
		Five-Ton Vehicles

2	Hood	36 by 6	36 by 5 dual
3	Hood	36 by 5	42 by 6 dual
4	Hood	36 by 5	40 by 6 dual
5	Hood	36 by 6	42 by 5 dual

Motor Chokes Up at Low Speed

Editor The Automobile:—I wish you could help me out of my trouble which is as follows: I have a late model 1911 Ford open roadster which I bought new 2 years ago and which I have given very great care and the best of oils, etc. I have run it only about 2,650 miles and for the past 3 weeks it has been coughing and jerking which is really caused by a missing of one or more of the four cylinders but I cannot tell which one, as the plugs are all right, being new and clean. Have put in new wiring, taken off the cylinder head, and cleaned out the carbon deposits, readjusted and filed the points on the master vibrator which I am using instead of the vibrators of the regular coil. Have even tried out a different vibrator and also a different carbureter, a Holly. I am using a Kingston floating or ball valve auxiliary air type, but there is no difference in either case on the magneto or on the batteries with either vibrator or coil. The occasional coughing or slow speed continues. Sometimes after adjusting the vibrator points or the needle valve to a different adjustment, the engine will run fine for a short time, and after congratulating ourselves, it begins to cough again, occasionally almost stopping. It sounds as though it did not receive the current and was taking in all air, as you can hear the loud rushing of air through the air intake hole of the carbureter.

Have had the Ford agents here to do the rewiring, adjusting and testing, etc., and it has them guessing so much that they are now trying to tell me that many of the Fords will not run idle or less than 8 miles an hour without occasional missing, but I know that my engine did, and as I am not fond of racing, it annoys me greatly, besides attracting more or less attention, which I do not like. Hope that you can suggest something that will lead to a remedy.

Portage, Wis. L. E. Grant.

—When an engine misses at low speed, suspicion is always directed to the valves. Since you do not mention that you have had the valves ground lately or at all since you have had the car, the trouble will probably be found there. A car, when new, very often exhibits slight signs of valve trouble after it has traveled its first 500 miles. The new seat placed upon the valves does not endure in a great many instances nearly as long as that taken by the valve after its next grinding. It is reasonably sure to assert that if you have the valves ground in, provided you have not done so, the result will be a tight motor that will fire at as low a speed as it is possible to secure good carburetion.

Should you desire to grind in the valves yourself, a few directions as to how to proceed may be of assistance. The first difficulty you will have will be to remove the key beneath the lower valve spring pad. This is generally done with a regular valve lifting tool but the following home-made apparatus works very simply and can be made in a few minutes with the aid of a hacksaw and a piece of pipe.

In Fig. 2 an explanation of the method of procedure in arranging the lifter is given. The motor is turned over slowly by means of the flywheel until the valve is lifted to its highest point. The motor is allowed to rest in this position and the distance from the base of the tappet guide to the lower part of the spring seat is measured. In turning over the motor the petcocks should be open so that there will be no difficulty in this respect. A piece of pipe is then cut down through the middle along the dotted lines shown in Fig. 2 and slipped beneath the spring seat to hold it in its compressed condition. The motor is then turned over again and the valve will follow the tappet through its own weight instead of through the spring action as the spring will be held away from the valve. When the tappet has gone as far down as it will, the space between the tappet and the bottom of the valve stem is filled by a block of metal or other hard substance. A nut filed down to the right thickness will often serve the purpose very well.

Lift Will Be Doubled

When this is in place the motor is again turned over until the valve is once more in its highest position. This will be double the lift that occurred before on account of the addition of the block of metal to the length of the valve stem. The spring will be lifted off the improvised pipe seating and another and longer piece of pipe inserted as shown in the illustration. The motor is then turned over again and the tappet allowed to come to its lowest position. The valve is allowed to drop down and the key can be withdrawn. This will permit of the spring being removed and will leave the valve free for grinding.

Good valve-grinding compounds can be purchased in any of the automobile supply houses. It is better to buy a prepared grinding compound because if you rely simply on purchasing emery the grade that you are given is apt to be irregular and the valve seating could be spoiled quickly. Before putting the valve-grinding compound on the seat of the valve, stuff a piece of waste into the cylinder port so that there will be no possibility of the compound working its way down into the cylinder. This would ruin the cylinder in a very short time.

A thin layer of the compound is spread on the valve seat and the valve brought lightly and squarely down upon it. There are two methods by which the valves can be ground by hand, Fig. 3, one with a brace and bit and the other by means of a regular screwdriver. The brace and bit is the quicker and at the same time the more dangerous because of the tendency to put too much pressure on the valve. If carefully handled with a light pressure it will serve very well. The screwdriver is slow but at the same time is safer for the inexperienced. It is true that with the screwdriver a lame wrist must not be considered too much of a hardship in exchange for a smooth-running car, because unless the muscles of the wrist are accustomed to hard work they are almost sure to feel the effects of the job for a couple of days.

The method of procedure with both instruments is practically the same except, of course, for the method of handling the tools. The valve is revolved about half way and back. This is done about ten times and then the valve is lifted off the seat and turned to a different position and the same operation again gone through. It is easy to see what this will do to an unaccustomed wrist using the screwdriver as it takes about 40 minutes to seat a valve. The valve is taken out and examined and when a polished appearing seat begins to appear, the grinding compound is removed and the finish given to the seat with ground glass. A final test as to the tightness of the valve is to place it in its seat and pour gasoline on it. If none leaks through past the seating valve is tight. If signs of a leak appear, however, the grinding must be continued.

Fig. 3—Grinding work can be done either by a plain screwdriver or a brace and bit

The English engineers posing for a group photograph shortly after their arrival in the United States

S.A.E. and I.A.E. on Lake Trip

(*Continued from page* 1155)

can sing, so it is necessary to recognize all of the essentials of such production before it can be realized. That is a great art—the knowing how to make an automobile.

It isn't being practiced in the making of cars today in Detroit. Old-fashioned common sense is worth more than all of the modern cost-keeping and efficiency methods today employed.

"Don't worry about your competitors," Mr. Leland told the engineers. "Show them the very best product which you are able to produce in your plant and tell them that if they can do better to do so for the good of all concerned. The automobile business is one of the greatest benefits of today and if we can in any way further its development we help all. If anyone wants to go anywhere and get back, he gets in an automobile and does it without the inconvenience of the steam cars or the other older methods of transportation. There is a demand in the United States alone for 30,000,000 automobiles and China is awakening.

Requirements for Manufacture of Ideal Car

"This is the answer to the question often asked as to the ultimate destiny of the automobile business. If you make a good car that sells itself, the public which is aroused by the advertising of all your competitors to the possibilities of automobiles in general, will buy your car. Let them create the demand and you give the public the car. How is the man who knows how going to make this ideal car? First, he must design a car which he believes to be the best to date. Then he must design for best speed over the roughest of roads and for reliability and comfort. Having all of these dissected, it is next necessary to decide upon the very best material of which each piece is to be made. Next comes the best machinery for each use and following that the best obtainable operators. Finally, these operators must be taught how to run this machinery at the best possible speed, so as to get the greatest speed for the accuracy desired, and the coarsest cutting speeds possible. After all this is accomplished there will be no need for inspectors.

"It costs less money to do high-grade work than it does to do cheap and sloppy work. Ideal production methods cannot be accomplished by militant organized workers, whose greatest aim is to see how they can get along without working."

Mr. Leland was not touching upon scientific management in his talk but said that he was dealing with the knowing how. This is the real thing, in addition to which it is necessary to have up-to-date machinery which you know is doing the best that can be done. Thus you get away from inspection, which is in the unproductive class. And you do not get any dividends out of the non-productive class. The right way is just as good as any other way.

In conclusion, Mr. Leland said that the more good automobiles which are made the better for all of the industry in general because the demand cannot be filled. One tour amidst the beauty spots without the handicaps of steam cars or boats is all that is needed to make the 30,000,000 prospects firm believers that they want cars. This is the reason they ought to have them.

"Only make them good ones."

Packard and Timken Axle Factories Visited

DETROIT, MICH., June 3—Today the program of instruction and entertainment for the visiting members of the I. A. E. and the S. A. E. included a trip in the forenoon through the plant of the Packard company and in the afternoon a visit of inspection to the works of the Timken Axle Co.

Leaving the hotel this morning at 9.30, the party was soon busily engaged in an interesting tour through the Packard factory. The works spread over an area of 37 acres. At the present time the factory is turning out twenty-one cars a day. Six of these are commercial cars and the remainder are divided among the different classes of passenger cars. A total yearly production of 3,000 cars is being made at the present time and of this number 1,800 are trucks.

The course through the Packard plant had been thoroughly mapped out in advance both literally and figuratively. Large white arrows painted on the ground showed each guide the route to pursue on the way through.

The assembly room in the building especially set up for jobs peculiar to truck work was the first visited. Here, the usual procedure of sending the chassis along the line was inverted. Instead, groups of specialized workmen went from chassis to chassis, each group doing the particular work to which they were accustomed.

The Packard company employs between 6,000 and 7,000 men and has a payroll amounting to $20,000 a day. There are 350 employees in the administration department alone. The welfare of the men has been taken care of in an extensive manner and the work done in this line was especially interesting to the English guests. A washroom is located in every department and a lunchroom on the grounds has a plant capacity of 1,500.

There is a doctor and an assistant constantly on hand and at the service of the men in case of accident. A hospital is located on the grounds and an ambulance and driver are in constant readiness.

The men work 52.5 hours a week. There is a single shift in all but two of the machining departments where it has been necessary to work nights to take care of the extra output due to the introduction of commercial cars in the line. The men are paid every 2 weeks and work 2 weeks ahead of the pay day. They are paid on the 15th of the month for work up to the first.

It takes 72 hours for a motor to pass through the assembling department. Rotating racks are used so that it is easy to work on the bottom of the motor by simply turning it over. While the crankshafts are being assembled the shaft is turned over at 350 revolutions a minute by belt driver. This is done to assist in spotting the bearings before hand scraping them to fit.

The testing of the motor provoked considerable comment on account of its rigidity before the road test. The motors are mounted on blocks and direct connected to dynamometers. The 38 motors are required to develop from 40 to 48 horsepower at 1,200 revolutions per minute and the 48 motors must develop 60 horsepower at 1,200 revolutions per minute before they are allowed to go on the road test. Inspection tags are attached to the motors running on the blocks and the power developed at 1,200 revolutions per minute is indicated upon them. If they fail to come up to requirements they are sent back to the assembling department for overhauling.

The road test consists of a thorough run until the tester is satisfied with the behavior of the entire car. The test is never less than 4 hours and very often much longer.

The testing work throughout the plant was of extreme interest and many of the groups lingered longest at work of this nature. Hydraulic tests on the waterjackets are made before the cylinders are passed along for assembling. A 30-pound pressure is put upon them in an endeavor to discover any faults in the casting which may have been disclosed by the finish grinding work that each casting is put through.

The men in the machine shops work on the premium system and in general the limits are generous enough on the work so that it is possible for the men to make from full time and a quarter to time and a half. In cylinder grinding work, for instance on the finish grind, time and a quarter is made on a fifty per hour limit. After the trip through the factory was completed the party gathered at a luncheon tendered by H. B. Joy, the president and the other officers of the company; while the Packard band consisting of employees of the concern played on the lawn outside the office building where the luncheon was served. After the luncheon was over cheers were given for President Joy and the Packard company. President Browne, of the I. A. E., made a short speech of thanks and the party fell in behind the band and marched to the waiting cars.

Timken Factory Methods Examined

In a few minutes the visitors again found themselves passing through another factory of absorbing interest, this time that of the Timken axle works. Here, over 175 tons of product are turned out in a day. This part of the plant is solely intended for the axle work. The Timken bearing factory is in Camden, Ohio.

The factory in Detroit covers about 250,000 square feet of floor space.

In one day 130 sets of passenger car axles are manufactured and nine sets of commercial axles, making a total of about 280 axles a day.

A railroad siding which runs the entire length of the factory on one side brings the raw material to the factory, and at the shipping platform at one end of the plant another siding takes away the finished product.

One of the most interesting pieces of work in the factory which was noted by the visitors was the method of hardening just the desired parts of a gear or other part. The whole gear for instance, is electrically copper plated while it is still a blank. The gear is then cut and when put in the hardening bath only the unplated or cut part of the gear will be hardened on account of the protecting sheathing of copper which renders the gear immune at those points covered to the process.

Labor-saving devices are shown all over the factory. One good instance of this is the punching of the holes in the brake bands. This is done while the piece is straight. The machine at work while the visitors were passing through was punching forty-six holes at a time.

Other interesting pieces of machinery at which the English guests spent some interesting moments were the device for grinding the steering arm ball to a perfect sphere, the enormous shears for cutting the heavy stock, the gear cutting machines and hobbers and the milling machine for grinding the springpads and axle faces at one operation lasting about 2 minutes.

The heat-treating work was also a great feature of the visit to those interested in forge work. In a small office the man in charge signals the condition of the furnace to the men tending the fires. Three lights are used one above the other. A red one is placed at the top, a white in the center and a green below. When the temperature is right the white is lit, when too high the red and when too low the green. A log is kept showing how the temperature of each furnace varied during each 10-minute interval of the day.

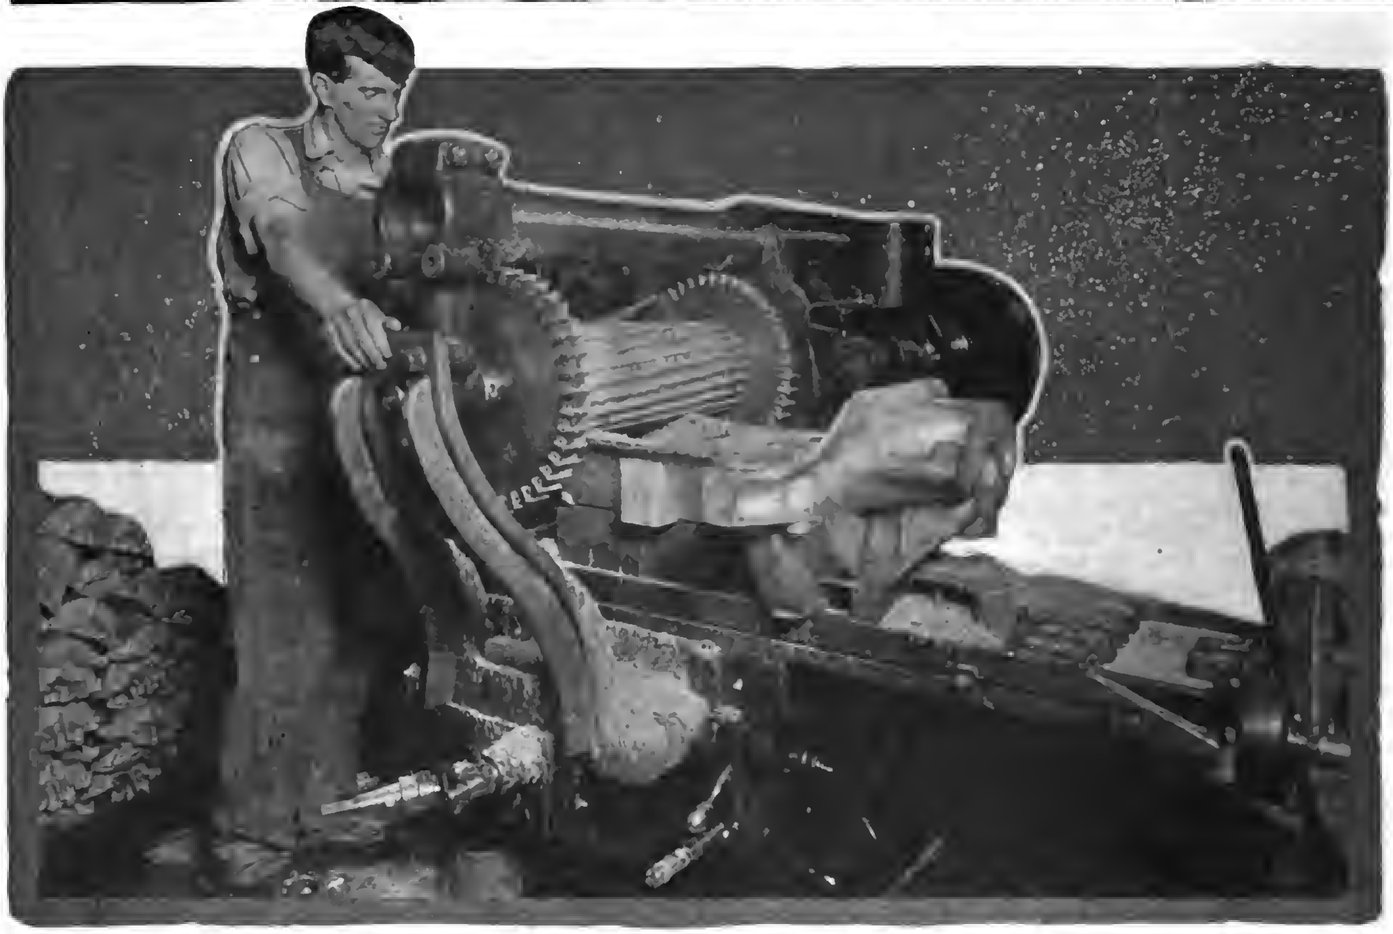
Party Embarks for the Trip Up the Lake

DETROIT, MICH., June 4—*Special Telegram*—Dated on the dock. The party of American and English engineers to the number of 600 are just embarking for their session on the steamer City of Detroit. This morning the program included a visit to the Continental, Hudson and Chalmers plants, at each of which the guests were welcomed by the officer of the respective company. The party terminated at the Chalmers plant, where a luncheon was served and a quick return was made to the hotel and thence to the steamer.

The following 3 days will be spent on the boat, and they will afford ample opportunity for the engineers to take up the principal work, for which they have been called to convention. On Thursday, June 5, business and professional sessions will busy the members of the S. A. E. and their friends from across the pond, and this work will take up the morning as well as the earlier part of the afternoon, while later on the Soo will be reached. At 6 p. m. the boat will leave Sault Ste. Marie and proceed on the lake toward Mackinaw Island, reaching it on Friday at 2 p. m. The morning of that day will again be taken up by professional work, a number of papers being scheduled for reading. After a stop of 4.5 hours, Mackinaw Island will be deserted and the steamer will go on with its return trip to Detroit, arriving there at 3 p. m. on Saturday, after the morning has been spent in a professional session once more. At 10 p. m. another steamer will take the engineers to Cleveland and thence east.

Group of members of the English Institution of Automobile Engineers and of the American Society of Automobile Engineers

Factory Miscellany



Special machine used in the factory of the Hupp Motor Car Co., Detroit, Mich., for milling crankcases and gearboxes

THE machine shown in the above illustration is of special construction and is designed for milling crankcases and gearboxes. The machine is used in the factory of the Hupp Motor Car Co., Detroit, Mich. Hupmobile crankcases and gearboxes are cast in one piece of aluminum. The gearbox shown in the picture begins at the end of the curve surface. The milling of this curve was one time thought to be a very difficult operation, which would require four or five different machinings. The engineers of the Hupp company devised this special spool-shaped cutter which grinds the entire case, curve and all, in one operation. The machine turns out sixty pieces of work a day, one man only being required for its operation. It is continually in use and never torn down. The saving effected is five-fold, the single machining process doing away with five separate machinings. Where time is saved principally in this operation is in having the cutters made as they are, milling the supporting arms of the gearbox, the straight line surface and also the curve section. Without this combination curve it would be necessary to handle the case five different times for the same amount of work. One piece of work is handled at a time. The machine occupies an area of about 36 square feet. It is standard No. 4 miller, the only special feature being the design of the cutters and the method of handling the job.

RUBBER Factories in Brazil—An impetus is to be given the automobile trade in all parts of South America by the establishment of rubber manufacturing plants in Brazil. In Brazil tires will be retailed considerably cheaper than in any other country. Other countries will profit by the lower freight charges. In addition to the Goodrich Tire and Rubber Co., Akron, O., which has a government contract for the erection of a factory and a washing plant, other firms will engage in rubber manufacturing.

Rubber Reclaiming Co.'s Plant—The United States Rubber Reclaiming Co., Buffalo, N. Y., recently filed plans for the construction of a factory to cost $2,000.

Gramm Plant Enlarged—The Gramm Motor Truck Co., Lima, O., will be enlarged this summer. It is the intention to increase the capacity to fifty trucks daily.

Goodyear Advertises for Workmen—The Goodyear Tire & Rubber Co., Akron, O., is advertising in Eastern newspaper for 2,000 working men, for its tire factory in Akron.

Universal Starts Factory Construction—The Universal Motor Truck Co., Detroit, Mich., recently incorporated under the laws of Delaware with a capital stock of $1,200,000, has begun the erection of a new factory adjoining its present plant and fully as large to cost, without machinery, $250,000.

Morgan & Marshall Awards Contract—The Morgan & Marshall Co-Operative Rubber & Tire Co., East Liverpool, O., has awarded the contract for the construction of a plant 90 by 107 feet. The work of construction will be started at once. The company will manufacture automobile and motorcycle tires.

Schachts Looking for Plant—G. A. Schacht and W. C. Schacht, formerly manufacturers of the Schacht automobile, Cincinnati, O., will re-enter the automobile business, and are looking for a factory they can buy. As soon as one is obtained equipment will be installed and work started making motor trucks.

Davenport Firm Is Reorganized—A complete reorganization of the Western Implement and Motor Co., a $2,000,000 concern organized in Davenport, Ia., over a year ago, was recently announced. The company will continue its manufacturing operations at the plant at Davenport until October 1, when the company will move to Cedar Rapids. This city made a flattering offer, which was accepted. The company will be given a $60,000 plant and a tract of 10 acres. The new plant will be completed about October 1.

Gramm to Build—The Gramm Motor Truck Co., Lima, O., will make important extensions to its plant in the near future.

Dominion Tire's $50,000 Building—The Dominion Tire Co., Berlin, Ont., has decided to erect a power house addition to cost $50,000, to be ready for operation in December.

Goodyear Factory in Seattle—The Goodyear Tire & Rubber Co., Akron, O., has commenced the construction of an elaborate factory building in Seattle, Wash. It will have a total floor area of 10,000 square feet.

Cole Doubling Production—The future production figures for the Cole Motor Car Co., Indianapolis, Ind., will double. A $150,000 addition to the present plant on East Washington street will be built, and the organization generally enlarged.

Dreadnought Tire's New Plant—The Dreadnought Tire & Rubber Co., Baltimore, Md., recently incorporated to manufacture rubber tires for automobiles, has secured a plant at Orangeville, Baltimore County, for its factory. The site has four acres of ground on which are seven buildings. Work will be started at once in rebuilding the Wilms plant so that the manufacture of rubber tires can proceed as soon as possible.

Four Wheel Drive's Factory—The Four Wheel Drive Automobile Co., Clintonville, Wis., has awarded contracts for the construction of factory No. 3, the largest addition to its plant, which is to be ready for occupancy July 1. After completion work is to be commenced on factory No. 4, which will be 100 by 120 feet, and similar to factory No. 3. A 40 by 40 foot house is also to be erected soon. The improvements will cost $75,000.

Pierce-Arrow's L. I. Building—The new service building now being erected at Freeman and Fifth avenues, Long Island City, for the Harrolds Motor Car Co., distributor of the Pierce-Arrow automobiles, has been completed as far as the steel work and the filling in of bricks and concrete has been commenced. The front of this building will be of gray brick with red and brown trimmings. The first floor will be 200 feet square owing to a one-story extension, while the remaining floors will be 80 by 200 feet. A smaller building, 50 by 100 feet, is being erected adjoining the main building, which will be used as a tin shop. This building is to be equipped with electrical apparatus the equal of that in the Ford building. The power equipment will total about 175 horsepower and in addition to the lighting and operating there is to be a fire apparatus which will be equipped with a 75-horsepower motor. In this plant at least 200 men will be employed when the building is completed, which will be about the middle of the summer.

Ford's L. I. Plant—The alterations to the Ford Motor Bldg., at Honeywell street and Jackson avenue, Long Island City, are about completed and this concern now has about 100,000 square feet of floor space which will be used entirely by the company for the assembling of cars. Parts will be shipped to that city from the Detroit, Mich., factory and about 150 more men than at present will be put to work in the assembling. It is proposed to assemble from fifty to sixty cars a day. One of the features of this plant is the use that will be made of electricity. Instead of the space given over to boilers and engines and the big smoke stacks that would ordinarily be found in a plant of this size, they are replaced by electric motors totaling 125 horsepower which will be used to drive elevators, air compressors and machine tools. On the roof is also to be erected a large electrical sign. This company recently completed the purchase of the entire block bounded by Honeywell street, Fifth avenue and Jackson avenue, and will shortly commence the erection of a ten-story building adjoining the present plant, which has been raised to eight stories.

New factory addition of the Sanford Motor Truck Co., Syracuse, N.Y.

The Automobile Calendar

Shows, Conventions, Etc.

June 2-7.......... Racine, Wis., "Made in Racine Exposition," J. I. Case Co.'s foundry.
June 5, 6, 7....... Detroit, Mich., Midsummer Meeting of Society of Automobile Engineers.
October 13........ Philadelphia, Pa., National Fire Prevention Conference, Philadelphia Fire Prevention Commission.
December 9-12...... Philadelphia, Pa., Annual Convention of American Road Builders' Association.

Race Meets, Runs, Hill Climbs, Etc.

June 5............ New York City, Orphans' Day Picnic at Glen Island, Orphans' Automobile Day Assn.
June 7............ Philadelphia, Pa., Inter-Club Reliability, Quaker City Motor Club, Automobile Clubs of Delaware County, Philadelphia and Germantown.
June 10........... Columbus, O., Reliability Run, Columbus Automobile Club.
June 14........... Cincinnati, O., Hill Climb, Cincinnati Auto Dealers.
June 14-15........ San Francisco, Cal., Track Races, E. A. Moross.
June, 16, 17, 18... Columbus, O., Reliability Contest, *Ohio State Journal*.
June 19........... Chicago, Ill., Algonquin Hill Climb, Chicago Motor Club
June 21........... Cincinnati, O., Hill Climb, Cincinnati, O., Automobile Dealers.
June 21........... Philadelphia, Pa., Fletcher Cup Run, Automobile Club of Philadelphia.
June 21-22........ San Francisco, Cal., Track Races, E. A. Moross.
June 23........... Des Moines, Ia., Little Glidden Tour, Iowa Automobile Assn.
June 25-28........ Chicago, Ill., Non-Motor-Stop Reliability, Chicago to Boston, Chicago Automobile Club.
July 1............ Indianapolis, Ind., Tour of Indiana Automobile Manufacturers' Assn. to the Pacific Coast.
July 1-16......... Winnipeg, Man., Motor Plow Competition, Dr. A. W. Bell, Manager.
July 4............ Columbus, O., 200-Mile Track Race, Columbus, O., Automobile Club.
July 4............ Taylor, Tex., Track Meeting, Taylor Auto Club.
July 4............ Washington, D. C., Track Races, National Capital Motorcycle Club.
July 4-5.......... Sioux City, S. Dak., Track Meetings, Sioux City Automobile Club and Speedway Assn.
July 5-6.......... Tacoma, Wash., Road Race, Montemara Festa Automobile Committee.
July 8-16......... Winnipeg, Man., Midsummer Exhibition, A. C. Emmett, Manager.
July 11........... Twin City, Minn., National Reliability Tour, A. A. A.
July 20........... Seattle, Wash., Track Races, E. A. Moross.
July 27........... Grand Rapids, Mich., Tour, Grand Rapids Auto Club.
July 27-28........ Tacoma, Wash., Tacoma Road Races.
July 28-29-30...... Galveston, Tex., Beach Races, Galveston Automobile Club.
Aug. 5............ Kansas City, Mo., Sociability and Endurance Run from Kansas City to Colorado Springs, Col., Kansas State Automobile Assn.
Aug. 12........... Kansas City, Mo., Reliability Tour, Kansas State Auto Assn.
Aug. 29-30........ Elgin, Ill., Elgin Road Races, Elgin Road Race Assn.
Aug. 30-Sept. 6.... Chicago, Ill., Reliability Run, Chicago Motor Club.
Sept. 1........... Columbus, O., 200-Mile Track Race, Columbus Auto Club.
Sept. 9........... Corona, Cal., Track Race, Corona Auto Assn.
Oct. 4-11......... Chicago, Ill., Around Lake Michigan Run, Chicago Motor Co.
Nov. 24........... Savannah, Ga., Vanderbilt Cup Race, Motor Cups Holding Company.
Nov. 27........... Savannah, Ga., Grand Prize Race, Automobile Club of America.

Foreign.

June 3-7.......... London, Eng., Third International Road Congress, Rees Jeffrey, General Honorary Secretary.
June 23-28........ London, England, International Road Congress.
July 12........... Amiens, France, Grand Prix Race.
July 13........... Paris, France, French Grand Prix Cyclecar Race.
July 15-30........ London, Eng., Olympia Heavy Motor Vehicle Show.

The Week in the Industry

Engineer — Dealer — Repairman — Garage

KisselKar patent combination uniform pressure street flusher and sprinkler, which has a 1,000-gallon galvanized steel tank

Showing the KisselKar sprinkler used as a flusher. Both the flusher and sprinkler are operated by hand levers

New model of the Locomobile Co. of America, Bridgeport, Conn., called the gentleman's roadster

NEW KISSEL SPRINKLER—The Kissel Motor Car Co., Hartford, Wis., is putting out a motor-driven sprinkler, as illustrated above. The vehicle consists of a 1000-gallon galvanized steel tank mounted on a regular 3-ton chassis. Pressure is produced by taking water by gravity from the bottom of the tank into two stage centrifugal pumps directly connected to the motor. Pressure can be had from 20 to 60 pounds, according to the speed of the motor. The water is forced from the pump into distributing pipes and out through two pipes to sprinkling attachments of vehicle type. The same pressure may be had when tank is partially full as when full, making it possible to get the benefit of all the water contained in the tank. The sprinkler will sprinkle the full width of a 60-foot street from curb to curb, or can be closed down to 20-foot streets. One tank of water will sprinkle 7 to 8 blocks of 50-foot roadway, or will flush a distance of 3.5 blocks.

POPE MOVES IN ATLANTA—L. S. Crane, Atlanta, Ga., agent for the Pope-Hartford automobile, has moved to 328 Peachtree street.

SHAW WITH EMIL GROSSMAN—G. E. Shaw has joined the technical staff of the Emil Grossman Co., New York City, as mechanical engineer.

WAITE NEW OAKLAND MANAGER—G. S. Waite has taken up the management of the Oakland Motor Car Co., 1600 Broadway, New York City.

REPUBLIC DAYTON DISTRIBUTOR—The Reliable Tire & Repair Co., Dayton, O., will act as the distributor for the Republic line of tires in that territory.

HARVEY SALES MANAGER—C. H. Harvey has been appointed sales manager of the Eastman Motor Car Co., Philadelphia, Pa., agent for the Wilcox truck.

BARDEN KELLY-SPRINGFIELD SECRETARY—G. W. Barden has been appointed secretary and treasurer of the Kelly-Springfield Motor Truck Co., Springfield, O.

FISK BRANCH IN HOUSTON—The Fisk Rubber Co. of Texas will open a branch in Houston. Three stories at 1305 Main street have been leased. C. B. Johnson will be in charge.

WALLACE FRISCO SALES MANAGER—W. D. Wallace has assumed his duties as the sales manager of the San Francisco, Cal., branch of the Franklin Automobile Co., Syracuse, N. Y.

METZ OPENS N. Y. QUARTERS—The Metz Automobile Co., Waltham, Mass., has opened temporary salesrooms on the second floor at 1700 Broadway. R. L. Rieser is manager.

AUGIER DIES IN PARIS—Albert Augier, general manager of the Paris branch of the Goodrich Tire Co., Akron, O., died at his residence recently as the result of a self-inflicted wound.

BATAVIA'S BUFFALO BRANCH—The Batavia Rubber Co., Batavia, N. Y., has opened a factory branch at 1030 Main street, Buffalo, N. Y., where its pneumatic tires will be carried in stock.

MOTOR OMNIBUSES FOR PHILADELPHIA—The Philadelphia Rapid Transit Co., Philadelphia, Pa., contemplates the installation of motor omnibuses on Broad and other streets not containing trackage.

EAST LIVERPOOL'S FIRE TRUCK—The city council of East Liverpool, O., has adopted a resolution appropriating $5,000 for the purchase of a combination motor-driven fire truck for the municipality.

BUS LINE IN TORONTO—A motor bus line is proposed in Toronto, Ont. The busses would be run as auxiliary to the street railway service as in Montreal, and other large cities. Buffalo, N. Y., also soon is to have the motor bus line.

VESTA ACCUMULATOR'S NEW QUARTERS—A lease for 10 years on a new building to be put up at 3024 Locust street, St. Louis, Mo., was recently made by the Vesta Accumulator Co., Chicago, Ill. The building is being erected and will cost $10,000.

TIMES SQUARE CO. ADDS—The Times Square Auto Co., New York City, has filed plans to immediately erect two additional stories on its present quarters at 56th street and Broadway. Each floor will have an area of 20,000 square feet, which will give it a total space increase of 40,000 square feet.

New Pierce-Arrow Features—The Pierce-Arrow Co., Buffalo, N. Y., is now using an electric self-starter instead of its former air system. It is now placing its headlights on the front and mudguards instead of as heretofore on brackets either side of the radiator.

Peugeot Opens New York Office—The Peugeot car which won the 500-mile race at Indianapolis, Ind., last week is now represented in New York City, A. G. Kaufman having taken the agency for this country with offices at 1620 Broadway. Henry Taylor is sales manager.

By Way of Correction—In the issue of May 29 in the lead article named Indianapolis, a typographical error was made by stating the first electric vehicle built by the Waverley Co., Indianapolis, Ind., was delivered to Charles Finlay Smith in 1907. This should have been 1897.

Potter Severs Vanderwater Connections—M. H. Potter has severed his connection with Vanderwater & Co., Elizabeth, N. J., manufacturer of the Correga cars. He has connected with a new company in Montreal, Que., and will continue along the same lines, but in a broader field.

Large Milwaukee Garage Leased—The garage of the Kopmeier Motor Car Co., of Milwaukee, Wis., considered the largest in the Northwest, and situated at 375 Summit avenue, has been leased for a long term of years by Hustis Bros., representing the Stevens-Duryea and Borland electric.

Five Ambulances Motor Driven—With the installation of the fifth motor-propelled ambulance at the charity hospital in New Orleans the last of the horse-drawn wagons of this type have been withdrawn from the service. In the future only motor-driven ambulances will be maintained by this big institution.

Kissel Service Station in Frisco—The Pacific KisselKar branch is having plans drawn and will soon break ground for a new sales and service building to be located on Van Ness avenue. It is intended to erect a structure that will eclipse in size the service station in Chicago, Ill., which contains 70,000 square feet of floor space..

Yale Mfg. Co. Bankrupt—The Yale Mfg. Co., of Oostburg, Wis., manufacturing automobile accessories and specialties, has filed a voluntary petition in bankruptcy, giving its liabilities at $27,272.76 and assets at $29,326.95. The company was organized about 3 years ago by Milwaukee capital established a workshop at Oostburg.

New Service Stations—The Pope Hartford Co. of Boston, Mass., and the Republic Motor Co. of Massachusetts, the latter handling the Little and Chevrolet cars, have had to get new service stations in Cambridge, the former adding a new building to its present one and the other company leasing 10,000 square feet in the Shoe & Leather Bldg.

Price Dunlop Manager Dies—Hubert Price, general manager of the French Dunlop Tire Co., dropped dead in the streets of Paris recently. He was an Englishman and 41 years of age, came to Paris about 20 years ago to fill a position with the Clement Cycle Co. He later joined the Dunlop Co., and after a short period was appointed general manager.

Orphans' Day, June 11—Secretary Chester I. Campbell of the Boston Automobile Dealers Association, Boston, Mass., has selected Wednesday, June 11, as the day on which to give the blind, crippled and orphaned children an outing. More than 400 cars will be used and the youngsters will be taken to Nantasket beach instead of to Sharon as formerly.

Top Co. in Bankruptcy—Zimmerman & Son, Waupon, Wis., manufacturers of tops, curtains, cushions, etc., and in business for 47 years, have filed a voluntary petition in bankruptcy. The property will be sold June 7 to satisfy the demands of creditors. It is said that the failure of an automobile manufacturing company which owed the Zimmerman concern a large sum for material and finished goods, was the indirect cause of bankruptcy.

Corning Orders Fire Apparatus—Corning, N. Y., placed an order recently with the American-La France Fire Engine Co. of Elmira, N. Y., for a new motor six-cylinder fire pump and new motor combination chemical and hose wagon, two apparatuses to cost $14,500. The Elmira fire engine concern agrees to sell Corning's horse-drawn vehicles and turn over proceeds to the Corning department, which will be used toward purchase of the new motor wagons.

German Sales Increase in Brazil—Increasing sales of German cars in Brazil is declared to be due to the fact that full lines of repair parts are carried in stock by the agents of the German manufacturers. American cars are popular, but parts can be obtained only by sending to the United States. Government statistics for 1912 show that 2994 cars of European manufacture entered the republic, while 783 American cars were received. Those familiar with conditions declare that the proportion could be reversed if the business was intelligently nursed for a year or two by American manufacturers.

Wreck of an automobile caused by Nebraska's second tornado on May 14. Automobile firms and owners in Nebraska are considered lucky, for very little damage was reported to automobiles. Seward was the principal scene of the most damage and loss of life. Here eight people were killed, twenty injured and a property loss of $100,000 was recorded. The automobile in the above illustration was taken from a private garage and deposited about 100 feet, and another machine was blown into its place in the garage without suffering serious damage

Detroit, Mich., branch of the Willard Storage Battery Co., Cleveland, O. This branch is in charge of M. G. Hillman

Ascent of Grassy Alp, about 40 miles outside of Detroit, Mich., made by a Studebaker car

MACNEIL HEADS EXCELSIOR RUBBER—W. N. Macneil is now heading the Excelsior Rubber & Supply Co., Winnipeg, Ont.

NEW BUICK BIRMINGHAM SALESROOMS—New salesrooms have been opened by the Buick Agency in Birmingham, Ala. The new quarters are expensively appointed. The new site is at Avenue D and 20th street.

RACINE ADDS FIRE APPARATUS—The common countil of Racine, Wis., has confirmed the action of its committee awarding the contract for furnishing two motor-propelled fire engines to the American-La France Fire Engine Co., of Elmira, N. Y., at $17,000.

MORE FREIGHT CARS ORDERED—The Great Northern road has ordered 1500 automobile freight cars. Altogether three northwestern roads will spend $25,000,000 for new rolling stock and the Great Northern's proportion is $16,000,000. The company will buy altogether 9,050 cars.

AUTOMOBILE MAIL SERVICE IN ARGENTINA—Mail and passengers are to be carried on a new automobile line from Rosario, Argentina, to several small places in the interior. Four cars will be used in the service, which will maintain schedule. The government pay for the mail is sufficient to cover the expenses of operation. The returns from the passenger business are expected to be sufficient to cover the interest on the investment and leave a fair profit to the owners.

NEW HOME FOR CHALMERS—The last lot of land on Commonwealth avenue, Boston, Mass., between the buildings occupied by motor concerns and the parkway that was vacant has been sold and upon it will be erected salesrooms and service stations, one of which will be occupied by the Whitten-Gilmore Co., that handles the Chalmers line in Boston, as well as the Federal and Standard trucks and the Woods electric, and the other is said to be leased to the Franklin agency.

AUTOMOBILES IN URUGUAY—Few South American cities, in proportion to the number of inhabitants, show as many automobiles in use as Montevideo, yet the number is increasing very considerably. During December and January no less than 115 high-priced cars entered this port and were sold. There are more than 1,300 cars licensed in Montevideo, about 2,000 being the total for the whole republic. Of the machines in use there, those of American manufacture are well represented, numbering about one-half of the total.

CO-OPERATIVE MOTOR BUS SERVICE—A co-operative motor bus service modeled after the system in force at Indianapolis, Ind., is proposed for Milwaukee, Wis., by leading grocers and marketmen. The plan includes the issue of 5,000 shares of stock, with a limit upon the number that may be held by any one member, and provides for an initial service of 12 trucks. It is planned to give the consumer complete control of the service by an arrangement of the sale of stock, and to divide profits equally among stockholders. Merchants along any main thoroughfare may organize a company on the same basic principle, in which every citizen with $10 to invest may become a stockholder and thus part owner of a passenger bus, increasing his or her chances for a dividend every time the person rides on one of the busses. J. A. Bayliss is promoting the scheme in Milwaukee.

NEW LA FRANCE GARAGE—The La France Garage Co., Elmira, N. Y., has completed its plans for the new building and garage at Church and Baldwin streets, and the builders are ready to begin construction as soon as the small buildings have been removed from the property. The new building will be four stories in height, with a basement. The exterior is to be of white brick. The construction will be brick and concrete. The building will be of L shape, 60 feet front on Church street, 116 feet deep on Baldwin street, with a wing extending east from Baldwin street, 41 feet wide and 120 feet deep, extending in the rear of a brick apartment house. The second floor of the building will be used for second-hand cars. The third floor will contain the repairs department, and the fourth floor will be a paint and finishing shop. The basement will be for temporary storage and the charging of electric cars and trucks.

Recent Incorporations in the Automobile Field

AUTOMOBILES AND PARTS

BOSTON, MASS.—W. J. Connell Co.; capital, $15,000; to deal in automobiles. Incorporators: W. J. Connell, H. D. Greene, H. J. Cramp, I. E. Thomson.

BROOKLYN, N. Y.—Barber Auto Service Co.; capital, $10,000; to deal in automobiles. Incorporators: William Barber, A. S. Barber, M. F. Barber.

CHICAGO, ILL.—Divine Motor Car Co.; capital, $10,000; to deal in automobiles. Incorporators: E. C. Divine, H. E. Campbell, W. R. Mitchell.

CLEVELAND, O.—H. & H. Auto Co.; capital, $10,000; to manufacture and deal in automobiles. Incorporators: F. M. Fogarty, J. O. Fordyce, A. B. Brackenridge, H. M. Reidel, G. M. Dolan.

DETROIT, MICH.—Universal Motor Truck Co.; capital, $1,200,000; to manufacture motor trucks.

JERSEY CITY, N. J.—Hudson & Bergen Automobile Co.; capital, $125,000; general automobile business. Incorporators: R. E. Fulcher, C. Moller, A. A. Leets.

MANITOWOC, WIS.—L. J. Anderson Co.; capital, $20,000; to deal in farm machinery, gasoline engines, automobiles, tractors, and similar prime movers. Incorporator: L. J. Anderson.

MAYSVILLE, KY.—Brown Auto Co.; capital, $4,500; to manufacture automobiles. Incorporators: Mike Brown, W. B. Tully, S. M. King.

NEW YORK CITY—Asch & Co.; capital, $1,000; to deal in automobiles. Incorporators: B. M. Asch, Leonard Veith, W. M. Goldsmith.

NEW YORK CITY—Gadabout Motor Corp.; capital, $250,000; to deal in automobiles, motors, etc. Incorporators: A. V. Clarke, Charles Vail, D. E. Dealy, Jr.

NEW YORK CITY—H. S. Houpt; capital, $60,000; to deal in automobiles. Incorporators: L. A. Van Patten, I. H. Westervelt, L. W. Bagley.

NEW YORK CITY—Universal Equipment Co.; capital, $50,000; to deal in internal combustion engines and motors. Incorporators: George Gray, T. W. Hatfield, I. B. Owens.

ST. LOUIS, MO.—Grand St. Louis Auto Co.; capital, $4,000; to deal in automobiles. Incorporators: L. B. Scherer, E. A. Stosberg, J. J. Scherer.

SYRACUSE, N. Y.—Syracuse Auto Radiator Co.; capital, $50,000; to manufacture automobile radiators. Incorporators: Max Kalman, Mrs. Minnie Kelman.

WHEELING, W. VA.—Union Automobile Co.; capital, $25,000; to deal in automobiles and accessories. Incorporators: W. T. Shaffer, A. C. Shaffer, A. M. Schenk, G. P. Fahnar, B. J. Smith.

WHEELING, W. VA.—Auto Supply House; capital, $25,000; to deal in automobiles. Incorporators: H. W. Rogers, T. A. Westmyer, J. P. Arbens, Minnie Rogers, Anna B. Westmyr.

GARAGES AND ACCESSORIES

ANTIGO, WIS.—Holland Flexible Auto Wheel Co.; capital, $10,000; to manufacture a new type of wheel for motor trucks. Incorporators: T. J. Holland, J. L. Donahue, J. E. McKenna.

BUFFALO, N. Y.—Easy Starter & Speeder Sales Co.; capital, $1,000; to manufacture automobile self-starters. Incorporators: F. A. Coon, H. J. Schopf, J. E. Schuesler.

CANTON, O.—Reliable Puncture Seal Co.; capital, $25,000; to deal in automobile accessories. Incorporators: L. W. Steinmetz, W. V. Baird, P. S. Wise, J. R. Binns, E. D. Myers.

CINCINNATI, O.—K. Auto Delivery Co.; capital, $10,000; to do a general automobile trucking. Incorporators: Edward Konker, G. W. Bell, Anna Konker, Gus Konker, F. Schmidt.

CLEVELAND, O.—Air Tank Carbureter Co.; capital, $10,000; to manufacture apparatus for the generation or mixing of gas for power or light. Incorporators: Edward Younder, L. C. Loomis, F. Castle, W. J. Engel, James Kelly.

CLEVELAND, O.—Cleveland Ball Bearing Co.; capital, $10,000; to manufacture and deal in ball bearings and other parts for automobiles. Incorporators: Henry Merkel, G. M. Merkel, P. J. Probeck, W. A. Crawford, C. H. Warner.

NEW YORK CITY—Lake Sales Co.; capital, $25,000; to deal in piston rings. Incorporators: H. S. Lake, J. A. Walker, R. B. Wasson.

NEW YORK CITY—Triumphant Tire Society; capital, $500; to deal in tire, rubber goods, etc. Incorporators: E. R. De Tamble, Louise Bennett, E. A. Swanson.

NORFOLK, VA.—Auto Specialty Co.; capital, $25,000; to deal in automobile accessories. Incorporators: T. G. Coburn, F. D. Belote, I. B. Belote.

PHILADELPHIA, PA.—National Tire & Rubber Co.; capital, $50,000; to manufacture automobile accessories. Incorporators: Harry Fisher, Benjamin Haas, Louis Greenhalt, J. G. Hughes, H. W. Davis.

TOLEDO, O.—Babcock Garage Co.; capital, $10,000; to operate a garage and do repair work. Incorporators: C. Wagenhauser, L. P. Wagenhauser, A. G. Der, Bernard Hubert, C. F. Souder.

WICHITA, KAN.—Hockaday Auto Supply Co.; capital, $15,000; to deal in automobile supplies. Incorporators: Ray Hockaday, F. W. Hockaday, C. E. Hockaday, James Pryune, F. W. Martin.

WILMINGTON, DEL.—Bernstein Automobile Accessories Sales Co.; capital, $15,000; to construct, maintain and operate machinery and devices for cleaning windows.

WORCESTER, MASS.—Electro Signal Co.; capital, $50,000; to manufacture an automobile signal. Incorporators: W. M. Waite, J. H. Wheelock, Zella E. Wheelock.

CHANGES OF NAME AND CAPITAL

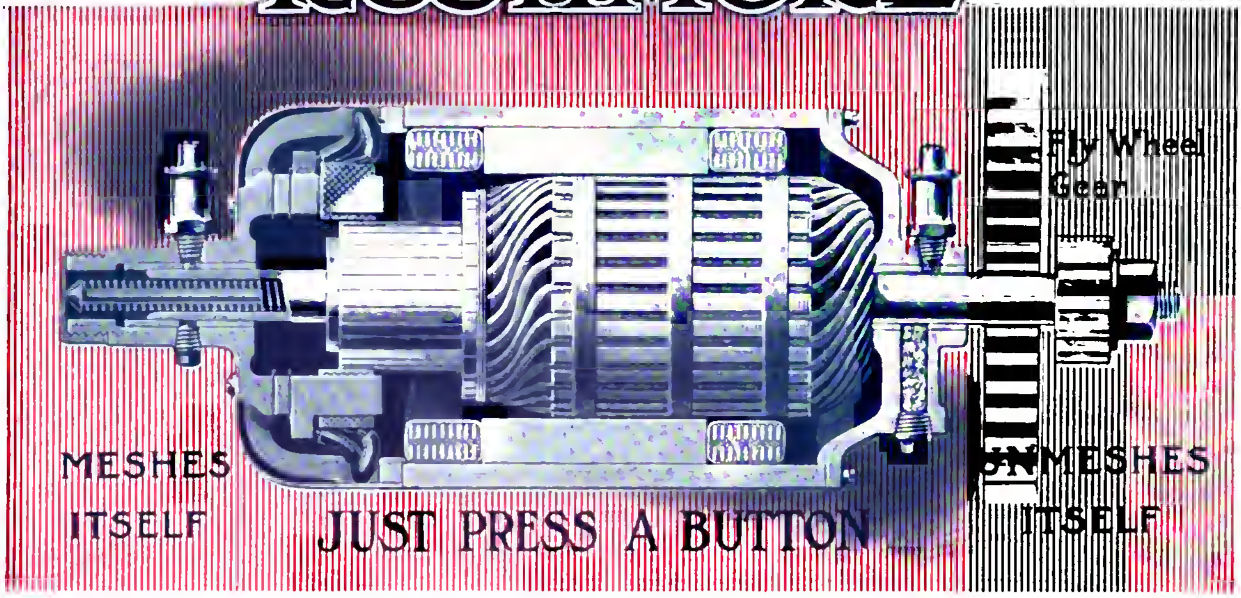
RUSHMORE



Not Even the Commutator Needs Cleaning!

Did you ever hear of a starter so totally free from tendency to wear itself out that not even the commutator needed attention?

Probably not; yet that very thing is true of the Rushmore Starter!

If you have the Rushmore System on your car there is literally **nothing** to do to keep it in order except to squirt a few drops of oil into the oil cups once a week.

Like the other sensational Rushmore features, this one has a good reason behind it. The motor is purposely so arranged that a little of the oil from the bearing finds its way to the commutator and lubricates the brushes. The latter are copper, and consequently of negligible resistance. As the Starter runs only when starting, both the wear and the demand for lubricant are at the lowest minimum. Our tests have shown that in thousands of miles the commutator needs absolutely no attention and can simply be forgotten by the user.

Substantially the same is true of the Dynamo. Unlike the Starter, it runs all the time; but the commutator and the current carried are small. The brushes are of graphite and self-lubricating. Besides that, they are absolutely sparkless: there is no arcing or burning to damage the surface of the commutator.

These things did not happen by chance. The Rushmore Starting and Lighting System is the product of a scientific investigation into the entire subject of automobile starting and lighting, and was developed after all other systems had been analyzed and rejected for inherent faults. The Starter operates, and the Dynamo governs itself, without any of the mechanism commonly thought necessary, yet both are completely automatic.

Engineers Close Session

Lake Trip Even Greater Success Than Last Year—Big Program Carried Out—English and Americans Unite in Work and Play

By J. Edward Schipper

DETROIT, MICH., June 7—Today marked the close of the summer session of the Society of Automobile Engineers and Institution of Automobile Engineers of England held on board the steamship *City of Detroit III* while cruising on Lake Huron to the Soo, Mackinac Island and back. Combining business and pleasure the second annual cruise was an immense success both socially and in an engineering way. The long program was almost entirely carried out, the exceptions being the omission of some of the topics for discussion and two papers which were not read owing to the absence of their authors.

The attendance was excellent, 569 passengers being carried, of whom 50 per cent. were engineers and the remainder associates and members of their respective families. At the sessions in the main saloon held in the morning and afternoon of Thursday and the mornings of Friday and Saturday attendance averaged 200.

Among those in the party were the chief engineers of a score of the leading automobile manufacturers, engineers of many of the leading parts manufacturers, and engineering representatives of metallurgical concerns engaged in steel and iron manufacture. A percentage of the party was made up of the selling representatives of concerns holding affiliate memberships. Among the party were Past-Presidents Howard Coffin, Henry Souther and Thomas J. Fay.

Let their varying efforts unite for the best interests of motoring in both nations

Every opportunity was afforded for mixing business with pleasure during the 4 days on the boat. On Thursday there was a 4-hour stop at the Soo, when the American locks were inspected. On Friday 6 hours were spent on Mackinac Island, this being ample time for driving and walking parties to explore the entire island. Naturally nearly all of the party took advantage of the opportunity.

Important developments took place at the meetings, the work done by the various divisions of the standards committee was watched with great interest by both the members of the S. A. E. and I. A. E. Ten divisions were called upon for committee reports. Out of these there were three submitted reports which were accepted, one, that on iron and steel with an amendment. The other two accepted were of the nomenclature and miscellaneous divisions. All the other committees reported progress and many important ones promised reports for the winter session. Among the latter are the ball and roller bearing, commercial car wheel and sub-committees of the electrical divisions. The committee reports will be found on page 1220.

President Marmon opened the meeting Thursday morning with a short speech of welcome to the British guests and members, stating that the greatest and most important works of the society are its efforts along the lines of

One-quarter of a panorama view of the majority of the members of the S. A. E.—I. A. E. party at Mackinac Island

standardization begun some years ago. The society has made immense progress in this and has succeeded in creating standards that have been accepted throughout the entire automobile industry.

President Marmon also dwelt to a large extent on the value of the section meetings. "It is these section meetings," stated he, "that hold the entire society together in a way that would be impossible were we to have only the semi-annual sessions."

I. A. E Honors Marmon

T. B. Browne, president of the Institution of Automobile Engineers of the British Isles, expressed the thanks of the British guests to their host, the S. A. E., and as an expression of gratitude, President Marmon was presented with an honorary membership in the I. A. E. This is a signal honor, as Mr. Marmon is the first and only honorary member of the I. A. E. To Coker Clarkson, secretary of the S. A. E., on behalf of the Britishers, who appreciated his tireless efforts in their behalf was presented with a silver card tray. Alden L. McMurtry, head of the transportation department of the S. A. E., was presented with a silver plate as a token of the visitors' appreciation of his work for them.

City of Detroit III, which was the home of the party for parts of 4 days on Lake Huron. There were 569 in all

The reports showed that the society is not falling off from its rapid growth. It now numbers 1,635 members. Since January the following elections have taken place: New members, 72; associates, 91; Juniors, 7; a total of 170.

Besides these four affiliates were elected.

The treasurer's report showed a balance of $6,557.84 in the treasury. Since the last meeting held in New York in January the total receipts and disbursements of the society have been:

Receipts	$25,637.30
Disbursements	19,079.46
Balance	$6,557.84

An important feature of the session was a resolution of the society against the Oldfield patent bill now pending before Congress. This bill menaces the rights of holders of patents and, in fact, does much to rob the inventor of the fruits of his invention. Milton Tibbetts, head of the Packard patent department, read a paper he had prepared and read the resolution. In this he cited the fact that the progress of the age and the advance in civilization are due to the work of inventors. The society unanimously adopted his resolution, which was "that the president of the S. A. E. appoint a committee on patent investigation on behalf of the inventors and that the progress of its investigations be reported to the society." The committee consists of Messrs. Milton Tibbetts, Herman Cuntz and Howard Coffin.

The committee went quickly and vigorously to work and at the final session furnished its report, which included the following

Resolution:

Resolved: First; that the Society of Automobile Engineers is opposed to the Oldfield bill; second, that it is opposed to any fundmaental changes in the patent law without thorough investigation and fair public hearings; and third, that a copy of this resolution be forwarded, on behalf of the society, to every Senator and Representative and to other engineering societies.

In the professional program the Britishers played an important part, presenting four of the papers read and participating generally in all discussions. President Browne, of the I. A. E., told

Third quarter of the panorama, showing how many of the men came out in comic costume

Second quarter of the panorama of the party, which formed into a circle with the camera in the center

of the growth, development and construction of gasoline omnibuses in London; Thomas Clarkson, the leader in the manufacture of steam buses in London, delineated their advantages and present-day status; Charles Wheeler, head of the motor transport department of the British post office, spoke on calculating efficiency; and E. B. Wood, Bristol, on the measurement of horsepower.

In the program presented by the American engineers twelve pertinent subjects were considered: Paul W. Litchfield, factory manager of the Goodyear company, gave an exhaustive treatise on the pneumatic tire situation of today, his paper being sufficiently elementary to be followed by a layman, yet most up-to-date.

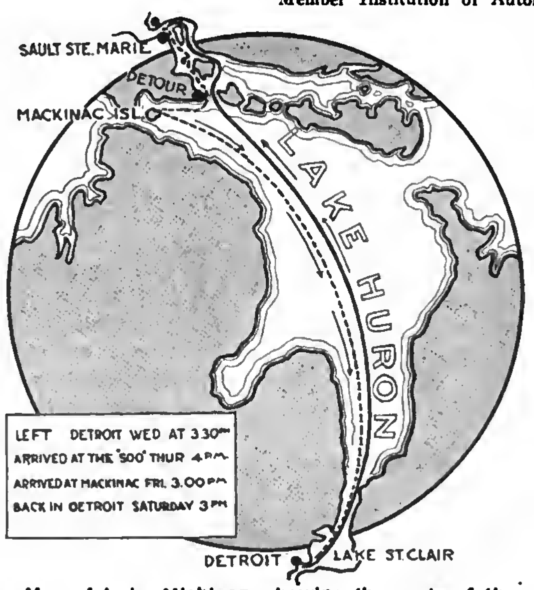
Houk on Wire Wheels

George W. Houk, representative of the Rudge-Whitworth wire wheel interests in America, read a comprehensive paper on wire wheels, drawing attention to their light weight and enumerating their various advantages and disadvantages for passenger car use.

From an engineering viewpoint Enrique Toucedal's paper on malleable iron was of leading interest, in that this metal is coming into more general use in motor car construction and, although more or less ridiculed by engineers to date, it is now arousing great attention, due to improvements in methods of handling it.

The interest of users and makers of commercial motor vehicles were well looked over, an entire day being given over to the reading of papers on relevant subjects and the discussions on same. The entire program follows:

A New Tensile Test-Piece and Holder.—By K. W. Zimmerschied.
Pneumatic Tires.—By Paul W. Litchfield.
Lubricating Oil.—By Harry Tipper.
Manufacture and Physical Properties of Malleable Iron.—By Enrique Toucedal.
Petrol Buses.—By T. B. Browne, President, Institution of Automobile Engineers.
Steam Buses.—By Thomas Clarkson, Member of Society of Motor Manufacturers and Traders.
Calculating Depreciation of Commercial Automobiles.—By Charles Wheeler, Member Institution of Automobile Engineers.
Jackshaft versus Double Rear-Wheel Brakes. By Arthur M. Laycock.
Metal Wheels.—By Arthur J. Slade.
Automobile Production Inspection Methods. —By E. F. Roberts.
Influence of the Sales Department on the Design of Motor Cars.—By F. E. Moskovics.
Wire Wheels.—By George W. Houk.
Motor Construction.—By Claude E. Cox.
The Measurement of Horsepower.—By Prof. W. Morgan, B. Sc. and E. B. Wood, M. A.
Notes on Power Variations with Atmospheric Changes.—By Herbert Chase.
A Consideration of Certain Problems of Carburetion.—By Arthur B. Browne.



Map of Lake Michigan, showing the route of the S. A. E.-I. A. E. excursion from Detroit to the Soo, to Mackinac Island and back to Detroit

Cruise a Delight

The route taken by the boat on its 4-day cruise was a real delight. Steaming up the Detroit River into Lake St. Clair, the shores of Ontario and Michigan are one-half mile distant. The river widens into the lake, the shore on the Canadian side receding until it is no longer visible. At the north end of the lake, a 40-minute sail, the waters again narrow and the boat passes into the St. Clair River and, 30 miles farther on, enters Lake Huron. The course lies lengthwise of the lake, far out of sight of land, to Sault Ste. Marie, familiarly designated the Soo. From the Soo, the return trip was started via Mackinac Island and thence to Detroit.

The steamer left the dock at 4 p. m., Wednesday. The weather was all that could be desired and a large crowd accompanied the members of the party to the pier. As the boat cast off and

The fourth quarter of the panorama shows how many ladies accompanied the party on board the City of Detroit III started up the Detroit River, the members of the party who had tramped many miles through the mazes of the Continental, Hudson and Chalmers plants that morning were glad to seat themselves on deck and take a much-needed rest in the quiet enjoyment of the sail up the river.

After dinner the evening was spent in various ways throughout the different parts of the boat. A dance was in progress on the main deck, while others joined in the songs on the saloon deck.

The boat landed at the Soo at 4 p. m. Thursday. The landing of the boat was the signal for the rapid conversion of a large gathering of dignified engineers into a yelling tribe of Indians. The natives lined the streets of the sober little town, while the engineers marched through them in impossible attire consisting of various disjointed sections of feminine clothing and with their heads protected from the invisible sun by large Japanese parasols of various gaudy colors.

Officers Society of Automobile Engineers on board City of Detroit III. Top row, left to right—Coker F. Clarkson, secretary; Henry Souther, past-president; Arthur B. Cumner, committee on arrangements. Second row—C. B. Whittelsey, council; J. G. Perrin, first vice-president; Russel Huff, second vice-president, and lower left, Howard Marmon, president

Only two hours were allowed at this port, but by the end of that time every visitor to the town felt perfectly at home. The little German band which had been hired for the occasion marched proudly through the main streets at the head of the noisy procession, while the rear was brought up by an enthusiastic mob of small boys.

Some Visit the Locks

A goodly portion of the more sober-minded members took a walk up to the fresh-water locks, for which this place is noted, and watched the heavy freighters go through.

The embarkation of the shore party at 6 p. m. would have broadened the smile of the Sphinx. The ill-assorted chorus of improvised musical instruments, mingled with the hoots of the small boys in one inharmonious squeal, would have shamed the best efforts of the imps of Dante's inferno.

The features of the entertainment of the evening on board were the Gridiron meeting of the Bonnie Boys of Britain and the camp-fire trial of the Indian tribe in full war paint and feathers.

The Britishers, led by President Browne in a long white flowing robe, represented a group of inspectors sent to America to report on conditions in the automobile factories. These inspectors all reported to the leader and told what they had seen. All were dressed in white *robes de nuit* with the words "I am 'ere" inscribed on their chests. E. C. Paskall, one of the visitors introduced each of the inspectors as he made his report.

Great Fun

Basil H. Joy lamented on speed of the 4d factory, Thomas Norton despaired of the Backyard (Packard) car, H. M. Buist criticized the Cadillaqua, which runs on milk. (Employees in the Cadillac plant are furnished milk.) The others told of fearful (?) conditions of other plants. One told of the Riverside (Hudson) factory; another dilated on the Charmers (Chalmers) plant; a third spoke of the 'Opmobile (Hupmobile), and so on. The criticisms were ludicrous but the satire struck home in many cases and provided continuous merriment for the entire audience.

Following the English performance, which brought down the house, the famous tribe of Indiana Indians led by F. E. Moscovics entered the arena with suitable war whoops and brandishing of weapons. An improvised stake had been arranged and the captives, Howard Coffin, chief engineer of the Hudson; David Fergusson, of the Pierce-Arrow; E. T. Birdsall, of the S. A. E.; Charles Wheeler, of the I. A. E., and R. H. Combs, of the Prest-O-Lite company, were all brought and tied to the stake and given various degrees of punishment, which varied from burning all the way down to the compulsory purchase of liquid refreshment for every one on board the boat.

The boat landed at Mackinac Island at 2:30, just at the adjournment of the professional sessions on Friday. Every one immediately started ashore with the idea of exploring the island until 9 o'clock, when the boat sailed.

Members of the British delegation in comic costume used for their humorous entertainment given Thursday evening. J. Inglis Kerr holding the flag

The amusements on shore consisted in roaming over the island, visiting the old fort, a relic of Indian days; watching the deer in the government reserve, admiring the picturesque beauty of Arch Rock, Sugar Loaf Rock, and a study of the old blockhouse.

The feature of the entertainment Friday night was the one-act playlet entitled, "Reverse English on the Heat Treatment," rendered by the Metropolitan Section of the society. The play showed the spirits of the Britishers in the realms of purgatory. The time was A. D. 2000, and each spirit was called upon by the Metal-archangel, Herbert Chase, to explain the reason for his presence.

The engineers with friends inspecting the locks at the Soo. The power house for operating the gates is in the background. The semi-crescent shaped recesses in the wall are the gates for the lock, both being open and the water at low level, or empty dock

A Big Hit

The whole performance made an immense hit, the take-off on the Britishers keeping them as well as the rest of the audience convulsed with laughter. The shade of Father Dunlop, of tire fame, appeared with the original tire carried over his shoulder; Steam-bus Clarkson and his whiskers, were among the condemned ones, as was also Froggy Pollock, the only Frenchman in the party. The chaffing was taken in the best of good nature and every one considered that it was an excellent return for the mischievious gridiron performance of the Englishmen given on the evening before.

Saturday morning was occupied by the last professional session, and once more the engineers, who vibrated rapidly between fun and seriousness, set themselves to work to plow through the heavy program. The session was started promptly at 9 o'clock and at noon most of the work had been cleaned up. The boat landed at Detroit at 3 p. m.

On board the steamer a morning and evening four-page news paper was published. The paper was complete in every way, having an editorial department of five men, consisting of Lee Anderson, Charles M. Steele, W. L. Agnew, F. Ed. Spooner and G. J. Hopcraft, a composing room and an electric print shop. The full news of all the social affairs on the boat were perused eagerly by the entire party. A large supply of cuts taken on board before the boat left livened up the paper considerably.

This marked the close of the midsummer session of 1913. From the boat the party scattered to their various hotels. The Britishers, with a small complement of American engineers, rechecked baggage and prepared for the completion of their itinerary, embracing Cleveland, Buffalo and New England points. Three of them took a midnight train for the Pacific coast on a sightseeing trip of their own, and a few took up their residence in Detroit for a 10-day visit in more leisurely fashion to its factories. A motion was made and carried that it was the wish of the members of the S. A. E. assembled here that the summer session of 1915 be held on the coast. No arrangements were made for 1914. This year the increase in the number of ladies in the party was very marked.

The report on the monument for the late Henry Donaldson, past-president of the S. A. E., was read by H. M. Swetland. The monument is to be erected in 60 days. The amount subscribed by the society was $300, although the cost will be less than this.

Cleveland, O., June 9—The party of English and American automobile engineers, whose numbers had dwindled from 600 to fifty since leaving Detroit, arrived here yesterday.

Today's program included a visit to some of the more important factories in Cleveland. Among these were the works of the Foote-Burt Co., Cleveland Automatic Machine Co., National Acme Mfg. Co., Ferro Machine & Foundry Co., the White Co., and then optional visits to the Perfection Spring, Warner-Swasey, Peerless, Stearns, Winton, Baker and Rauch & Lang plants.

Buffalo, N. Y., June 10—*Special Telegram*—Today the program of the visiting party of engineers called for a visit to the Pierce-Arrow plant in Buffalo and then an afternoon at the Falls of Niagara. The party was met at the pier on arrival from Cleveland at 7.30 this morning and after breakfast on the boat, a tour was made through the Pierce factory, which is now turning out 3,500 passenger cars and trucks a year. The afternoon was spent as guests of the Pierce company at the Falls where a supper was served. The party of English engineers here broke up into three, one-third going to New York, a third going to New England and the rest scattering through the West.

A group of the American engineers and their friends before the monument at Mackinac, in uniforms secured for celebration purposes

Quaker City Team B Wins Interclub Run

Protest Has Been Lodged Against One Member of the Team

GETTYSBURG, PA., June 7—Team B of the Quaker City Motor Club, consisting of Paul B. Huyette, Peerless; S. Leon Gans, Cadillac; R. L. Murray, Packard; I. T. Shoemaker, Ford, and H. M. Lyman, Packard, captured the trophy in the interclub reliability run which was successfully conducted today under the combined auspices of the Quaker City Motor Club, the Automobile Club of Philadelphia, the Automobile Club of Germantown and the Delaware County Automobile Club, from Philadelphia to Gettysburg.

The result is subject to revision, however, as a protest has been lodged against No. 62 of the successful team on a technicality involving the eligibility of Mr. Murray's car. The protest, if sustained, would give the trophy to Team A, also of the Quaker City Motor Club, which finished second with a penalization of 21 points. The team from the Automobile Club of Philadelphia finished third, 28 points being chalked up against it. Neither the Automobile Club of Germantown nor the Delaware County Automobile Club made any entry.

The event, the first of its kind for Philadelphia's motoring organizations, proved very popular and enjoyable. Very few frills and furbelows were attached to the rules for governing the contest. Entrants were divided into teams of five cars each for each club, the team finishing with the least number of points penalization being declared the winner. Only club members who were private owners not connected with the trade were eligible to compete.

No time or place was designated for the start from Philadelphia, contestants being free to leave from any point at any time and to choose any route, the only stipulation being to check in here before 3 o'clock to escape penalization. For each minute or fraction later one point was assessed against the car.

Weather conditions favored the start, and as a consequence all fifteen cars entered competed and came through with nothing more serious than punctured tires. Rain was falling by the time Lancaster was reached, but ceased soon. By the time tops had been hurriedly adjusted it was nearly over, and the run was made more enjoyable by reason of the laying of the dust.

Most of the participants took advantage of an invitation extended by the York Automobile Club to stop over and inspect that organization's cosy headquarters. Lack of time prevented the acceptance of a similar invitation from the Pullman Motor Co.

Headquarters were established here at the Eagle Hotel, and after checking in most of the tourists kept their cars in action for trips throughout the battlefield, which presented a striking appearance with its many tents being erected for the 3-day encampment of the Civil War survivors, starting July 1.

The start for Philadelphia will be made at irregular intervals to-morrow.

Officials of the run were P. D. Folwell, referee and representative A. A. A. Contest Board; manager, Dr. J. R. Overpeck, and B. H. Kirkbride, timer. The summary follows:

QUAKER CITY MOTOR CLUB (TEAM B)

No.	Entrant	Driver	Car	Arrived Gettysburg
63	I. T. Shoemaker	I. T. Shoemaker	Ford	12:00
62	R. L. Murrsy	R. L. Murray	Packard	1:40
61	S. Leon Gans	S. Leon Gans	Cadillac	2:08
60	Paul B. Huyette	Paul B. Huyette	Peerless	2:27
64	H. M. Lyman	H. M. Lyman	Packard	2:59

QUAKER CITY MOTOR CLUB (TEAM A)

No.	Entrant	Driver	Car	Arrived Gettysburg
54	F. C. Dunlap	F. C. Dunlap	Cadillac	2:23
51	A. T. James	Ralph James	White	2:50
50	F. G. Nixon-Niedlinger	F. G. Nixon-Niedlinger	Pierce-Arrow	3:00
53	Frank Hardart	Erma Hardart	Winton	3:07
52	Frank Hardart	May Hardart	Elmore	3:14

AUTOMOBILE CLUB OF PHILADELPHIA

No.	Entrant	Driver	Car	Arrived Gettysburg
1	Thomas Devlin	Thomas Devlin	Pierce-Arrow	12:30
2	Frank Silvers	Frank Silvers	Peerless	12:45
5	R. C. Schworer	R. C. Schworer	Lozier	12:52

3	Harvey Boyd	Harvey Boyd	Hupmobile	3:28

Mitchell-Lewis Glidden Pathfinder

MINNEAPOLIS, MINN., June 10—*Special Telegram*—Mitchell-Lewis Co., of Racine, has offered a Pathfinder car for the A. A. A. tour which will leave Minneapolis on June 14. Frank Hirbies, the driver, is on his way from Atlanta. The official folder of tour has been issued and mailed to all prospective entrants, and A. G. Batchelder, of A. A. A. will arrive at Minneapolis next Monday night for a mass meeting enlivened by a stereopticon lecture in the commercial club on the subject of the Glacier Park and the route of the tour.

Aitken To Go with Goux

INDIANAPOLIS, IND., June 9—Because of the excellent service he rendered Jules Goux, winner of the 500-mile race at the Indianapolis Motor Speedway, Memorial Day, Johnny Aitken of Indianapolis probably will go to Europe to assist the Peugeot team during the Grand Prix. Aitken may be accompanied by Howard Wilcox, who drove the Gray Fox in the Indianapolis event.

TACOMA, June 4—That Tacoma's dirt auto race track will be in such shape as to offer opportunity for the breaking of all existing dirt track records seems to be indicated by the trials made on it by Felix Magone, driving a Fiat. Magone made the 3.5-mile circuit in 3.14, or better than a mile a minute.

LOS ANGELES, CAL., June 7—It has been definitely decided that the Panama-Pacific Road Race will start from Los Angeles at 1 minute past midnight, July 4, and finish in San Francisco on the afternoon of the Fourth. Entries close June 10 and cars entering after that time will be forced to pay a larger entry fee.

New Sunbeam for Brooklands

LONDON, ENG., June 1—Great things are expected of a new Sunbeam which will shortly be put into operation on the Brooklands track, with the express purpose of cutting out a few world's records. This machine will have a twelve-cylinder engine and will be capable of developing well over 200 horsepower. The cylinders will be 3.15 inches bore by 5.9 inches stroke, set V-fashion at 60 degrees to each other.

The angle at which the cylinders are set has an important bearing on the torque obtained, and the performance of this latest speed machine will be watched carefully to note what effect the almost perfect torque characteristic will have on the speed capabilities of the car. A little consideration will show that with twelve cylinders at 60 degrees there will be an impulse at every 60 degrees, that is, six impulses a revolution, producing an extremely smooth result at the shaft.

Columbus Club's 200-Mile Race

COLUMBUS, O., June 9.—The Columbus Automobile Club through its committee on races and contests will give the third annual 200-mile race at the Columbus Driving Park, July 4. This event is the classic dirt track race of the country and is known far and wide. Twelve entries have been received, which is the largest number that can be started on the track.

The purse for the event is $3,000, which is supplemented by a number of trophies given by manufacturers and business men. The timing will be done by the Baker electric timer. Governor Cox of Ohio is an honorary referee and Mayor George J. Karb of Columbus an honorary umpire.

In order to lay the dust, the committee in charge of the event will spread 30 tons of calcium chloride on the track. Among the cars entered are several Mercers, one of which will be driven by Spencer Wishart, the winner of the 200-mile race last year. The Smada and several foreign cars which participated in the 500-mile race at Indianapolis will also start.

The Columbus Driving Park holds all records on dirt tracks from 75 miles up to 200 miles. It is also the first dirt track in the country to stage a 24-hour race.

The committee in charge of the event consists of L. M. Browne, chairman; Frank J. Girard, F. H. Thorpe, J. C. McIntyre and J. W. Means.

NEW YORK CITY, June 11.—The Long Island Automobile Club has announced a run for its members on June 14, which will start from the club house at 2:30 P. M., and end there at 6:30. The contestants will have to touch four points in lower Long Island, and who ever does this while making a minimum mileage during the afternoon, will be declared winner of the W. C. Bolton trophy.

French Grand Prix Has 36 Cyclecars

Most Are Two-Cylinder Types—Race on July 13

PARIS, FRANCE, June 4—Final entries for the French cyclecar Grand Prix race at Amiens have closed with a total of thirty-six machines. These comprise twenty-five cyclecars of 1,100 cubic centimeters cylinder capacity; one of 750 cubic centimeters; seven cyclecars or sidecars of 1,444; one of 750 and two of 500 cubic centimeters. All these machines will race together, but there will be distinct awards for each class. This is the first occasion on which cyclecars have been united for a pure speed contest on the open road. Doubtless, as the result of this contest this already popular type of vehicle will experience a boom.

Practically all attention has been centered on the 1,100 cubic centimeter class (67.1 cubic inches), showing that this type of machine is the one with the greatest future. Sidecars, which are exceedingly popular in England, and have met with a little favor in France, are allowed to race with the cyclecars. Nevertheless only six of these machines have been entered. A team of four Morgan machines, which are officially placed in the sidecar class are really three-wheel cyclecars. The French regulations, however, do not consider three-wheel machines as cyclecars.

A small number of four-cylinder motors have been entered in the race.

At present the twin cylinder motor holds the greatest amount of favor. The single is not fashionable, and the four-cylinder is either too costly to manufacture or is looked upon as not so efficient as a twin of equal cylinder capacity. A few of the firms make four-cylinder motors but prefer to put a twin in the race.

The cyclecar race will be run on the afternoon of July 13, being the day following the big car race. The course is a triangular one shortened from the big car course, with the same grandstands and tire pit arrangements. Fifteen rounds have to to be covered, giving a total distance of 163 miles.

Complete Entries French Grand Prix Cyclecar Race.

Paris Show To Open October 17

PARIS, June 4—Paris will this year open the European show season with its annual exhibition in the Grand Palais, the inauguration of which has been fixed for Friday, October 17, and the closing day for Monday, October 27. The show will thus be open on 11 consecutive days, including 2 Sundays. The date chosen for this year's show is the earliest yet adopted for any motor exhibition in Europe. Henri Cezanne, who will again act as general manager of the Paris show, declares that this early show will allow the factories to gain practically 2 months. In France there is no important fall trade such as the American manufacturers enjoy. Thus, as soon as the active touring season is over there is a slackening off in factory activities and work is not taken up at full pressure until after the Paris show. By changing the show from December to October it is believed that this slack season will be reduced by 2 months.

Owing to the earlier date, there will probably be a smaller number of Parisians at the Paris show, but it is believed that the foreign visitors will be largely increased. Numbers of foreign visitors have not returned home in the month of October, and during this season buyers from business houses in all parts of the world are usually to be found in the French capital.

In its main features the Paris show will be similar to that of last year. It is organized by a joint committee representing the five leading trade associations of France and is run on a profit-sharing basis. Both pleasure cars and commercial vehicles are admitted, but the machine tool section has been abolished for lack of space. Accessory dealers are divided into two distinct classes: those manufacturing the goods they show and agents for other firms' goods. The minimum size of stands has been increased to 107 square feet, this having been done to make the cost of exhibiting too high for small dealers whose goods had but a slight connection with the automobile. The maximum size of stands is 861 square feet on the ground floor and 645 square feet on the first floor. All firms taking part in the Paris show must sign an agreement not to exhibit at any other show during the year in France or Algeria. Formerly this interdiction was only applied to the district around Paris. It has been extended to the whole of France in order to kill the small provincial shows which were springing up in all directions.

This year's show will be as brilliant as any of its predecessors. A very artistic uniform type of decoration will be adopted, and a considerable amount of money will be spent on illuminations. The opening ceremony will be performed by the president of the republic attended by most of the ministers. As the show lasts but 11 days, instead of 3 weeks as formerly, no free passes will be given out on the opening day. This will enable dealers to get to business immediately, whereas under present arrangements the hall has been so crowded with mere sightseers on the first day that no attempt could be made to transact business. The price of admission will be $1 on the opening day and on the following Friday and 20 cents on all other days. Instead of closing at 6 o'clock the show will keep open until 7 o'clock each evening.

The Paris show heading the list, there is every indication that the number of foreign exhibitors will be larger than usual. Naturally the entire French trade will be represented, and it is expected that English makers who have hitherto held somewhat aloof, will be present in big numbers. From inquiries having already been received from across the Atlantic, it is anticipated that American manufacturers will be present in big numbers. The French aviation show, which has previously preceded the automobile show, will this year be held in the Grand Palais during the month of December.

Humber Breaks Brooklands Records

LONDON, ENG., May 28—New figures in the short records of the Brooklands cubic capacity classes have recently been put up by the remarkably fast performance of the little 11.8-horsepower Humber, which succeeded in covering the flying mile in 44.56 seconds, representing a speed of 80.9 miles per hour. The dimensions of the four-cylinder engine fitted to this car are 2.77 inches bore by 5.12 inches stroke, giving a capacity of 123.6 cubic inches, which places it in Class B, for engines not exceeding 125 cubic inches.

The previous holder of the shorter records in this class was the Calthorpe, whose speed for the flying mile was 74.29. The Calthorpe engine, however, was slightly smaller than the Humber, having a bore and stroke of 2.74 inches by 4.92 inches giving a capacity of 115.7 cubic inches, well within the maximum for the class.

The short records captured by the Humber are: the flying half mile in 22.07 seconds, a spurt at the amazing speed for so small a car of 81.56 miles per hour; the flying kilometer in 27.44 seconds and the flying mile in 44.56 seconds. Besides these a new record for the ten-lap standing start was registered at the speed of 76.45 miles per hour, a gain of nearly 10 miles over the speed of the previously standing figure put up by the D. F. P. car with an engine of almost identical dimensions.

Court Upholds Hopewell

Rules That Vehicle Apron and Hood Co.'s Tire Cases Infringe His Patents

NEWTON, MASS., June 9—That the tire cases manufactured and sold by the Vehicle Apron and Hood Co., and handled in Massachusetts by the Linscott Supply Co., infringe patents Nos. 854,215 and 881,411 owned by Frank B. Hopewell of Hopewell Bros., Newton, Mass., was decided by Judge Dodge in the U. S. District Court of Massachusetts. The court stated that the three essential points covered by the two Hopewell patents mentioned were the annular form of the tire cases, the overlapping of the free edges of the sections which enfold the tires carried in the cases and the use of a cord in a longitudinal pocket, dispensing with the necessity of buttons and similar individual fastening devices. The combination of these features is original with the Hopewell patents, the court observed, and whatever evidences of prior art were referred to by the defendant did not embody that combination. There is even but one previous patent describing an endless tire case, that being Sloper's British letter of 1904, but this was considered impracticable by the judge. Other attempts made by the defendant to show that he made tire cases covered by the patents in 1905, while the alleged date of invention of the subject of the Hopewell patents was March 12, 1906, failed to be recognized as valid and convincing by the court, and plaintiff was entitled to an injunction restraining defendant from making and selling cases.

Ford Inforcing Cut-Rate Injunction

DAYTON, O.—A new phase was brought out by the Ford company in their nation-wide fight against the price-cutters today, when contempt proceedings were filed against the Union Motor Sales Co., of Dayton, O.

In the contempt proceedings the Ford people allege that the Union Sales Co. is guilty of violating the preliminary injunction issued in Judge Hollister's court here a few months ago. The petition was filed by Alfred Lucking and William Lucking of Detroit and Alfred M. Allen of Cincinnati, their attorney, against the Union Sales Co., Lucien A. Seward, its general counsel, and O. D. Nobel and H. J. Street, its sales managers.

In support of its charges the Ford Company filed with the court affidavits from residents of Wapakoneta, O., and St. Marys, O., whom the Ford company claim the Union Sales Co. called upon to have them buy cars at a price $50 to $500 lower than the regular retail price. An affidavit was filed from a newspaper at Wapakoneta to prove the assertion that an advertisement had been printed stating the cars would be sold for the low price. The court orders the defendant to appear June 26.

DETROIT, MICH.—While it has been announced definitely in some sources that the Ford Motor Co. is to equip all of its cars next year with wire wheels, James Couzens states that it has not yet been definitely decided to shift to this type of wheel although it is being seriously considered.

Grant Patent Owners Threatened

NEW YORK CITY, June 9—The preliminary injunction recently granted by Judge Ray in the U. S. District Court to James D. Hurd, the Consolidated Rubber Tire Co., and the Rubber Tire Wheel Co. against the James Goold Co., was reversed on appeal to the U. S. Circuit Court of Appeals, Second Circuit, New York. Judges Lacombe, Coxe and Noyes, who heard the case, were of the opinion that the three respondents who were maintaining suits against several New York tire dealers despite an order enjoining them from conducting such suits, were exposing themselves to the possibility of contempt of court proceedings, although the decision given by the tribunal admits the validity of the Grant patent in question. The judges were also of the opinion that the Goold tire infringed the Grant patent.

Court Sustains Prest-O-Lite Injunction

INDIANAPOLIS, IND., June 9—In the federal court here, Judge Albert B. Anderson has denied a petition of the Searchlight Gas Co. that an injunction against it in favor of the Prest-O-Lite Co. be suspended pending an appeal of the case to the United States Court of Appeals.

Judge Anderson at the same time entered a final decree in the case. The Searchlight company is perpetually enjoined from refilling Prest-O-Lite gas tanks before the Prest-O-Lite trademark is obliterated. Judge Anderson held refilling the tanks before the trademark was removed would be an infringement of trademark rights and unjust and unlawful competition.

NEW YORK CITY, June 9—In the Appellate Division of the N. Y. Supreme Court, the Searchlight Gas Co. argued against the Prest-O-Lite Co., against the latter's complaint that Prest-O-Lite tanks had been filled with Searchlight gas and that this action constituted a violation of the New York business law, trademark section.

The argument of the Searchlight Co. was fourfold: First, that the trademark law protects only foods, drugs and medicines, and that acetylene is not included among these; second, that only such products as come in a wrapper of no value are protected, while the law does not refer to products coming in a container sold like the Prest-O-Lite Tank; third, that the words of the Prest-O-Lite trademark refer to the tank and not to the gas in it; fourth, that the Prest-O-Lite Co. is a foreign corporation in the state of New York and as such is excluded from the benefit of the trademark law.

CINCINNATI, O., June 9—When the involuntary bankruptcy proceedings of the Eiseman Magneto Co. *et al.* vs. the Ohio Motor Car Co. came up for a hearing before Judge Hollister today on the motor car company's motion to dismiss and on objections filed to the motion by one of the creditors, the Judge after hearing the arguments denied the motion to dismiss and ordered the company to plead further.

The attorneys in support of their motion to dismiss the case argued that as the creditors of the motor car company had accepted a dividend of 15 per cent. on their claims in the receivership proceedings in the Hamilton county common pleas court that acceptance harred them from maintaining proceedings in bankruptcy.

Automobile Securities Quotations

Securities quotations were without an exception lower than last week. There were fallings off throughout, led by rubber stocks, Firestone common declining 29 and Goodyear common, 15 points. Studebaker and Willys-Overland also suffered severe setbacks. The entire movement was the result of the railroad decision rendered this week.

Chevrolet Buys Little

To Make 8,500 Cars for 1914—All Cars Now To Be Named Chevrolet

DETROIT, MICH., June 10—*Special Telegram*—The Chevrolet Motor Co. has purchased the entire business of the Little Motor Car Co., Flint, Mich., both being subsidiary to the Republic Motor Co. By the terms of the transfer the Little company goes out of existence as a separate, affiliated concern of the Republic Motor Co., and the cars made in the Little plants will henceforth bear the name of Chevrolet. The factory buildings occupied by the Little company in Flint were formerly the Imperial Wheel Works and the Randolph motor truck plant. The absorption of the Little concern takes effect immediately and the move is due to a plan for centralizing the manufacture of Chevrolet cars in Flint. It is proposed to make a complete line of cars there and the factories are to be in operation by August 1 with a schedule of 8,500 machines for 1914 ranging in five models from the small roadster selling at $690 to a six-cylinder type at $2,500. This will include several new models.

The Chevrolet company controls the sources from which it obtains motors and other parts. Its authorized capitalization is $2,500,000, of which $500,000 is preferred stock and the balance common. Along with the other changes several have been made in the personnel of the Chevrolet organization. N. W. C. Durant, formerly president of the concern, takes the first vice-presidency, while C. M. Begole assumes the duties of president. W. H. Little, who was general manager and second vice-president, leaves the organization entirely, and A. B. C. Hardy, who was general manager of the Little company, takes over the complete general managership and becomes a vice-president. C. R. Hatheway remains secretary, while W. S. Ballenger succeeds Dr. E. R. Campbell as treasurer. T. S. Johnston will be general manager of sales.

DETROIT, MICH., June 11—*Special Telegram*—The machinery, stock and equipment of the Flanders Mfg. Co., Pontiac and Chelsea, Mich., which went into the hands of the Detroit Trust Co., as receiver some time ago, have finally been sold to Harris Bros. & Co., Chicago, Ill., for the lump sum of $225,000. This concern has also secured a 3-months option on the plant and land for $175,000. The receivers will distribute a 25 per cent. dividend to the Flanders creditors next month, while another is expected to be given out in the fall.

Willys Reduces Hours But Not Pay

TOLEDO, O., June 9—John N. Willys has established a precedent in the automobile industry by announcing a general reduction of working hours throughout the Overland factories in Toledo, Lima, Elyria and Elmira, without a reduction of wages. The announcement provides for the substitution of the 54-hour week by a 50-hour week, all wages paid now remaining the same.

New Western Freight Rates

NEW YORK CITY, June 11—The Western Classification Committee which held a session in St. Louis during last April, has made several changes in railroad rates which will take effect on June 30. Below, the alterations as given out by James S. Marvin, general traffic manager of the Automobile Chamber of Commerce, are enumerated:

Article	Present Rate	New Rate
Chains, automobile tires in bbls. or boxes:	Less carloads. 1st class	Less carloads, 2nd class.
Fire apparatus, self-propelling.	Carloads, minimum, 24,000 lbs. Class A. Less carloads, various ratings as originally intended for horse-drawn and hand apparatus.	Specific rating installed on same basis as automobile rates, viz.: Less carloads, D-1. Carloads, 10,000 lbs. min., subject to Rule 6-B, 1st class.
Folding tops:	1½ times 1st class, carloads or less carloads.	Folded flat, in boxes or crates, less carloads 1½ times 1st class. In packages named, carload min. weight 10,000 lbs., subject to Rule 6-B, 1st class.
Automobile springs:	2nd class, carloads or less carloads.	In boxes, bundles or crates, less carloads, 2nd class. In packages, or loose, carload minimum weight 36,000 lbs., 3rd class.
Front axles, mufflers and radius rods:	Axles, 2nd class, carloads or less carloads. Mufflers and radius rods 1st class, carloads or less carloads.	Front axles, in bundles or loose, less carloads 2nd class. Mufflers, in bbls., boxes or crates, less carloads 1st class. Radius rods, in boxes, bundles or crates less carloads, 1st class. Front axles, mufflers and radius rods, in packages, or loose, straight or mixed carloads, min. weight 30,000 lbs. 3rd class.
Rear axle assembly with drive shaft attached:	1st class, carloads or less carloads.	In crates, less carloads, 1st class. In packages or loose, carload minimum weight 30,000 lbs., 3rd class.
Fenders, mudguards, mud shields or running boards, steel finished:	1st class, carloads or less carloads.	In boxes or crates, less carloads, 1st class. In packages or loose, straight or mixed carloads, minimum weight 30,000 lbs., 3rd class.
Frames:	1st class, carloads or less carloads.	Loose, less carloads, 1st class. Loose, carload minimum weight, 20,000 lbs., subject to Rule 6-B, 3rd class.
Dashes and steering gears:	1st class, carloads or less carloads.	In boxes or crates, less carloads, D-1. In packages or loose, straight or mixed carloads, minimum weight, 30,000 lbs., 3rd class.
Automobile wheels:	Without rubber tires: Finished, in boxes, crates, or wrapped, carloads or less carloads, 1½ times 1st class. In the white, loose, carloads or less carloads, 1st class.	Without rubber tires. Finished, in boxes, crates or wrapped, less carloads 1½ times, 1st class. In the white, loose, less carloads, 1st class. In the white or finished, in packages or loose, carload minimum weight 30,000 lbs. 3rd class.

Market Changes for the Week

Another break in tin occurred this week, due to small demand on large lots. A drop of $.75 was followed by lower prices and better demand for small lots, closing on Tuesday at $45.50 per hundred pounds. Lead was quiet and irregular, dropping $.02 1-2 per hundred pounds, closing at $4.32 1-2. The main feature of interest in the copper markets last week was the liquidation of speculative contracts of standard on Tuesday in London with a sympathetic lowering in prices and dullness in New York City. Electrolytic and Lake dropped $.00 1-8 and $.00 1-4 a pound respectively. Linseed oil dropped on Friday to $.47 at a loss of $.01. The situation in the market for petroleum underwent no change last week. The consumption continues liberal and the market retains a firm tone. Cottonseed oil fluctuated throughout the last week, the highest price at $7.22 and its closing price at $7.21 at a gain of $.06 per barrel.

S.A.E. Keeping Up-to-Date

LAST week's session of the Society of Automobile Engineers and the visiting members of the Institution of Automobile Engineers of the British Isles gave many evidences of the efforts made by the engineers to have their respective organizations leaders in the work of meeting exigencies or engineering conditions as they may arise in the automobile field. Many of the papers had a distinctly up-to-date atmosphere, dealing particularly with current movements in the industry. The paper and discussion on wire wheels, the use of metal wheels for motor trucks, and discussions on batteries for starting, indicated well the society's activity.

This activity might have gone a step or two farther and dealt with other subjects that are of paramount importance today. Time could have been spent to the greatest advantage in a general session on self-starters. At the last automobile show the self-starter was the word on the lips of everyone, and, although there was very general ignorance on the subject then it is equally certain that there is much today to be learned. No topic should have been of greater interest to the engineers in general, and no better opportunity will be afforded before the new models are out for going into this starter situation.

One other movement gives promise of receiving more attention during the next few months, namely, gear-shifting devices in which neither lever nor pedal is used. Not a few makers are looking into the question in an exhaustive manner and a good compilation on the subject, bringing it up to the present, would have been valuable to all members of the society.

The committees of the S. A. E. continue to do their valuable work of standardization as well as research. The work of a committee must always be considered the life-blood of an organization, and no better thermometer of health and activity can be had than the committee work.

One of the visiting engineers gave the excellent suggestion of carrying the standardization work into factory construction, into factory equipment and into factory operation. His plan carries with it the standardizing of all units comprising the factory. It goes further and deals with standardizing overhead shafting for driving machinery, suggesting that all electric motors be of uniform power, that all shafting be in uniform lengths or multiples of a given unit; that hangers for the shafting bearigns be standardized, so that in case any factory rre-arrangements become necessary it is possible to make changes with practically no expense and in a comparatively short time, whereas with a non-standardized factory arrangement each change or re-arrangement of machinery, or of a department from one part of the factory to another means a loss of valuable time and a considerable amount of money expended in addition.

American factories can take up such a movement and such a step lies within the zone of the S. A. E. in that the society has already dealt not only with questions of design and production but also with the merchandising of the product.

While congratulating the society on the excellent work it is doing, on its good financial condition and also on its steady growth in membership it is nevertheless true that more continuity of effort might be displayed in following up topics successively at later sessions. A year ago the question of arranging for some standard form of motor testing was gone into. At the January session a report was made but at the present session this work was largely neglected and the report passed on to the winter session. Motor testing is a most important feature, particularly in these days when higher motor efficiency is demanded. Many of the factories acknowledge how deplorably weak they are in adequate testing equipment. Because of this the subject should be vigorously pushed at each general session of the society.

Another criticism of the program of last week was that there were too many papers and not enough discussion. Every member agrees that discussion is the life of any subject. Discussion analyzes a subject for those who have missed the exact perspective of the question as presented in the address or paper read. When too many papers are read there is not enough time for free discussion. One of the policies of the I. A. E. is that one paper with discussion is sufficient for a 3 or 4-hour session. This is good policy for the S. A. E. to follow. If papers are not of sufficient importance to develop discussion then printing them in the S. A. E. Bulletin is sufficient. Many members are prevented from entering into discussions largely because they are aware of the lack of time. It is generally true that when several papers are read at one session the auditors become too tired to follow with the requisite mental alertness.

To Teach Massachusetts Children Safety

Movement Similar to American Museum of Safety League's Work in New York.

BOSTON, MASS., June 2—Motor accidents in which children are the victims will undoubtedly be decreased in Massachusetts in the near future due to the splendid plan outlined by the officers of the Automobile Legal Association and carried out successfully. It is a campaign of education, one not undertaken with the idea of advertising the organization, but solely to decrease accidents. Already it has cost the organization several hundred dollars, but the money has been well expended, for school children all over the state are now memorizing 10 simple rules for their own protection. Already more than 35,000 copies of them have been distributed upon request and the demand still continues. Miss Ripley of the Boston School Committee proposes to set the rules in rhyme and have the children sing them so that they may be memorized more easily and quickly before the vacation season begins.

Early in April the association sent the following letter to all the superintendents of schools in Massachusetts, and to the editors of various newspapers, also its members:

Dear Sir:—As the automobile season is about to begin and the streets of cities and towns will be soon crowded with that class of vehicles, we desire to inaugurate some sort of a movement by which school children and automobilists may co-operate for their mutual safety and the protection of school children in every possible way. This is a very large problem, which we are well aware will cost a great deal of money, but our association is now in a position to assist in this matter, and we write to ask if you will favor us with your suggestion as to how this best can be accomplished.

We have under contemplation a proposed set of say, six, eight or ten short rules with the idea of sending these rules to the school authorities of the cities and towns of Massachusets, asking them to have the children memorize them and repeat them in school at least once each week, but it seems to us if we go one step further and organize the children in some sort of a protective league, and make them feel that they are part of an organization which exists for their protection and interest, the movement would be more successful. We, of course, do not expect that education is needed by the children alone, and we are well aware that many automobilists need to be aroused to the necessity of greater care on their part, but the greater need of education, in our opinion, lies in the direction of pointing out to children who have not reached the age of discretion, a way in which they can co-operate with the movement. Hoping that we may hear from you at your earliest convenience with any suggestions that you may be able to think of, we remain.—AUTOMOBILE LEGAL ASSOCIATION.

The result was astonishing. The school authorities took it up from Boston to the end of the state. Suggestions came pouring in from many places giving the plan a good impetus. With this state the officials of the A. L. A. began their plans. The wheat was sorted from the chaff and so another letter was sent out this time to the superintendents of the schools. It said:

Dear Sirs:—Recently we mailed a letter to you asking for suggestions as to the best way to decrease the large number of automobile accidents to school children. Two suggestions, among many, have been made by a majority of the superintendents. The first is that an appropriate sign be erected from 200 to 300 feet on each side of school buildings. The second is that it would be well to have from eight to ten short rules printed on light cardboard and distributed to the pupils while in school each week until memorized.

From the replies received and from our own experience, we are convinced the sign should have the word "school" in large white letters on a red background. Such a sign would at once flash on the mind of the automobilist the thought of danger and of caution. In order that the interest of the children in this movement may be aroused at once, the suggestion has been made that we offer prizes to the children in the grammar schools, including all grades, for the best set of rules furnished. As we are looking for the idea rather than for perfect English—grammar and composition need not necessarily be considered. Each rule must not contain more than fifteen words.

We offer for the first prize, $25; for the second, $15; for the third, $10; for the fourth, $5, and for the next fifteen, $1 each, for a rule on each of the following suggestions:

1. What should a child do *before* crossing a street?
2. If playing in the street, what should a child keep in mind?
3. Why should a child not play in a street frequently used by automobilists?
4. What should a child do if standing in the middle of the street and automobiles are coming both ways?
5. What danger is there in stealing a ride upon an automobile?
6. In case a child, or any person is struck by an automobile what is the first thing to do?
7. Should a child throw a stone at an automobile and why?
8. Should an older child look after a younger and why?

These suggestions might be copied on the blackboard by the teachers for the guidance and assistance of the children in writing the rules. It may interest you to know that we shall also publish, at the same time the rules are finally adopted, a number of similar rules for the guidance of motorists. We ask your immediate co-operation in seeing that these rules actually originate with and are written by the children, whose full name and address should be given. Kindly impress upon the teachers that this contest will close on May 1 next.

After the rules received have been finally adopted we will notify you to that effect and give you the opportunity to order as many of them as you like, mailed to you at our expense.—AUTOMOBILE LEGAL ASSOCIATION.

Again the co-operation on the part of the school authorities was such that the suggestions were received and put into practice. Immediately there began the contest for the prizes from all over the state, for the teachers realized what a great benefit it would be to train the children to protect themselves while on the streets, particularly during the summer vacation. The association then took up the suggestion relative to signs and to all the mayors of cities and the chairmen of the boards of selectmen in every town throughout Massachusetts there were mailed letters seeking their co-operation.

Many replies have been received favoring this suggestion. Meanwhile the contest for the prizes offered by the association went merrily on. It was finally decided and the winner was a boy of 10 years of age. The winners represented cities and towns from one end of the Bay State to the other. Second, third and fourth prizes went to girls. The work will be resumed in the fall when the children return to school.

This movement is similar in its aims and purposes to the work being carried on by the American Museum of Safety, which has headquarters at 29 West Thirty-ninth street, New York City. For the past 8 months this organization has been engaged in conducting an educative campaign in the New York schools, endeavoring to instill into the school children an understanding of the dangers of traffic so that they may be persuaded to give up the street as a playground and especially to abstain from such dangerous pastimes as tag, roller skating, pushmobiling and "hitching on behind" automobiles and motor trucks.

Both organizations realize that due diligence in the operation of automobiles is only a casual factor in the situation. The criminal negligence of pedestrians and children is largely responsible for the increasing number of accidents in vehicle traffic. Restrictive legislation aimed at automobile owners and drivers is not the remedy required. The education of school children is the most logical method of approaching the trouble for when handled intelligently the serious side of the matter and the possibility of maiming or loss of life are impressed upon their minds in such a way that they instinctively protect themselves by increased carefulness.

How Children May Avoid Accidents

1—Before crossing a street, stop. First look to the left, then to the right, and if safe, go ahead.

2—If playing in a street remember you have selected the most dangerous place possible, and that the public streets are not made to play in.

3—In playing in the street bear in mind that automobiles come swiftly and silently, and, if they strike you, are very apt to kill you.

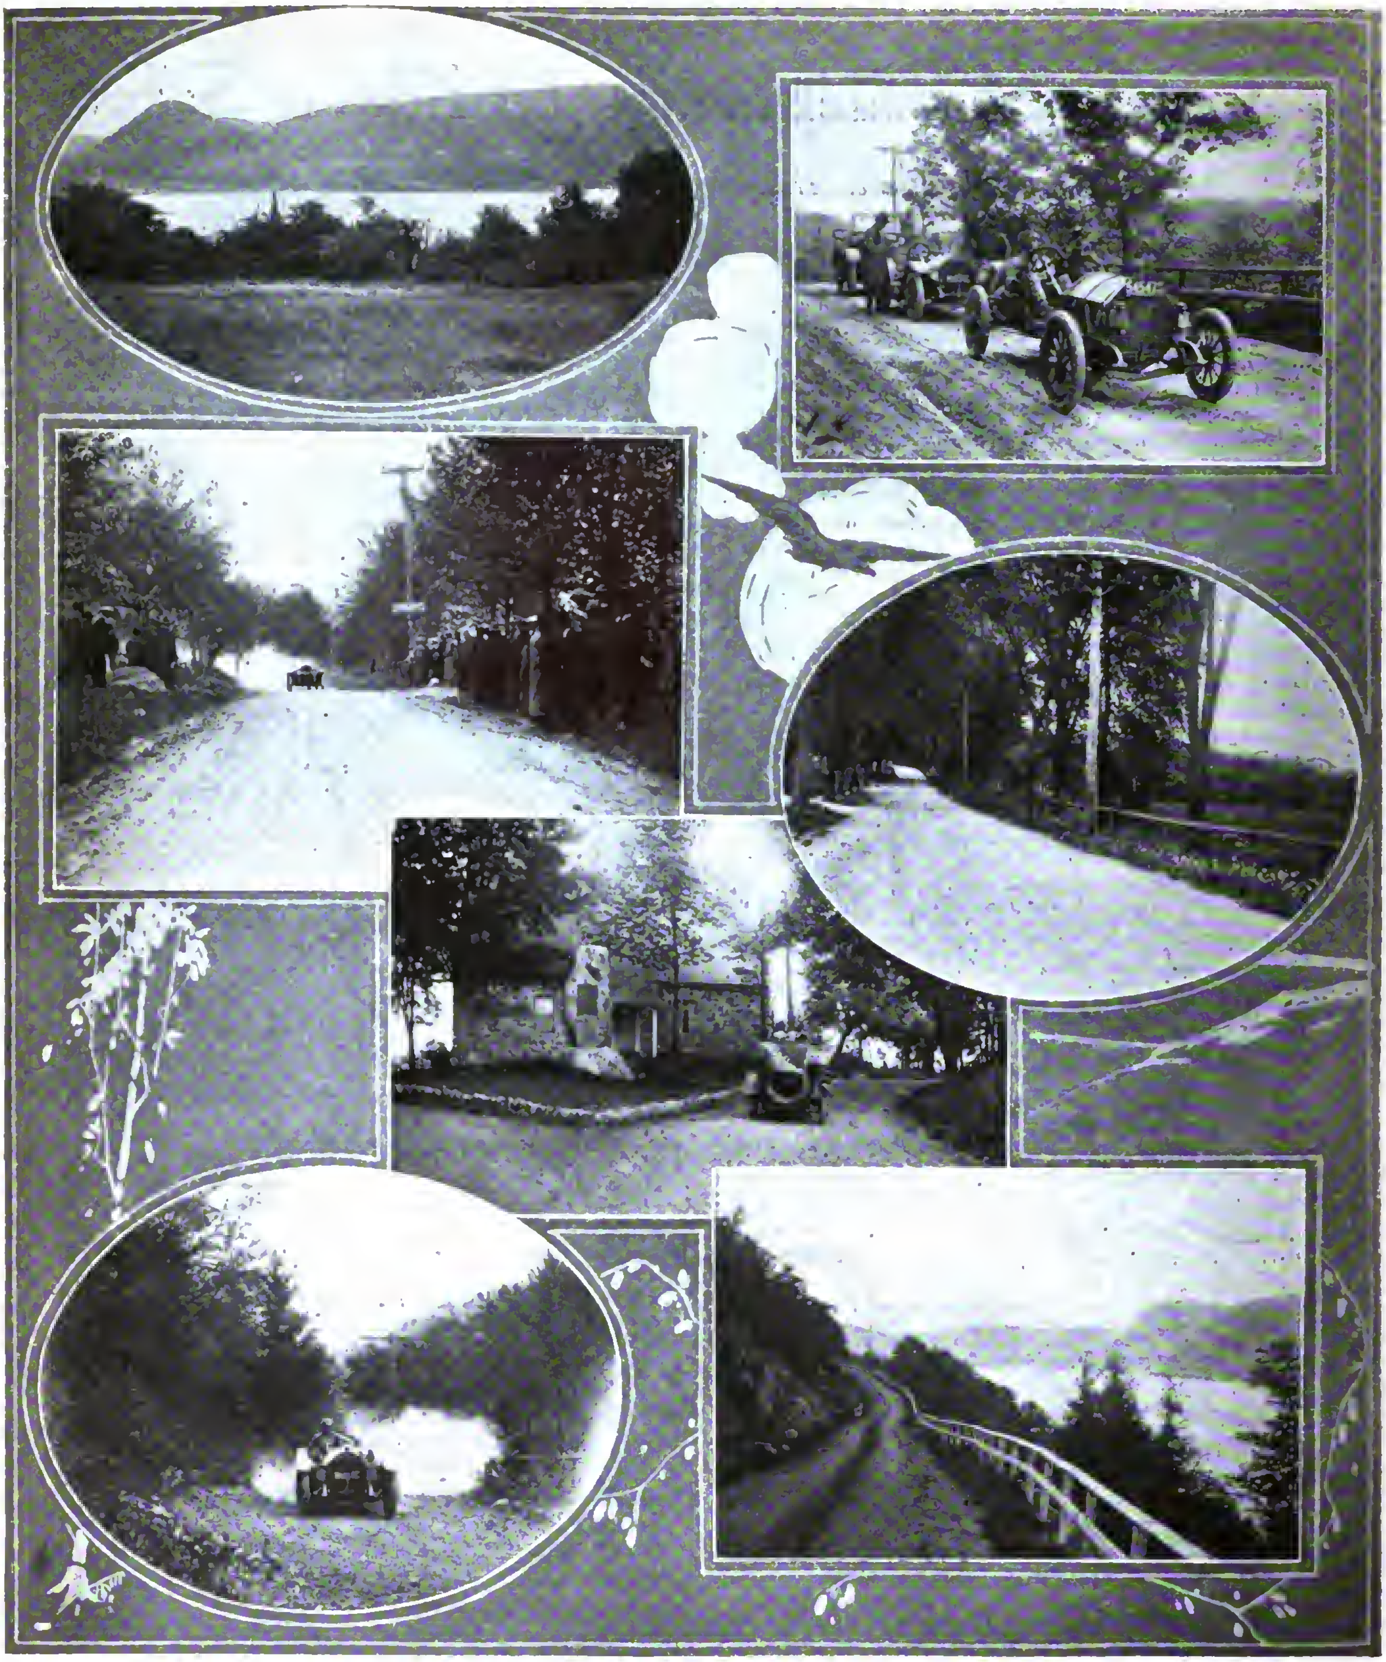
4—If standing in the middle of the street and automobiles are coming both ways, keep perfectly still.

5—The danger in stealing a ride is that if you are not thrown off, you are apt to be run over by another vehicle when you jump off.

6—In case anyone is struck by an automobile, first take the number, but be sure you take it accurately.

7—If you throw a stone at an automobile you may injure the occupants, or cause the driver to lose control; besides it is mean and cowardly. Don't do it.

8—Always look after a younger child because the younger cannot think quickly and does not know the danger.



SCENES along the road on the recent Catskill Reliability Run, held by the Motor Dealers' Contest Assoc. of New York City. The trip was an ideal one and the eleven cars had the best of weather conditions and fine roads on their 262-mile trip. The first afternoon's run to Newburgh was an economy contest and also a reliability run. This was won by the Paige-Detroit. The second day's run was divided into forenoon and afternoon runs. The forenoon run was from Newburgh to Haines Falls in the Catskills. This occupied but a part of the time, the remainder being taken up with a hill-climb, in which each vehicle had to compete, the driver alone riding. The Mercer won this. The afternoon run of the second day was made over good roads back to New York City by way of Newburgh and Tuxedo. At the finish when the eleven cars were checked, eight had perfect road scores. The economy contest proved one of the most interesting, in that the method of determining the winner gave the small car practically an equal chance with the largest machines. It would be difficult to select a better 65 miles for a fuel test.

ABOUT 5,000 children of assorted ages, colors and nationalities, from twenty-five of the city's institutions journeyed in automobiles from New York city to Glen Island on June 5. This was the ninth annual Orphans' Day of the Orphans' Automobile Day Assn. of New York. It required 344 motor vehicles of all kinds and descriptions to transport the children from the lower end of Central Park up Broadway and over to Glen Island, where they had luncheon and also visited all the various amusement places at that resort, returning to town, tired but happy, in time for supper. This outing was the largest of this character ever held. The time and effort which had been expended in making it possible by S. A. Miles, the association's president; Senator W. J. Morgan, W. S. Silver, F. J. Griffin, J. J. Korbel, R. H. Smith, H. A. Bonnell, P. B. Pugh and others of its officers and directors were more than repaid, however, by the delight which the day in the country under perfect June skies brought to the little orphans. The pictures show the little ones in passenger and commercial cars and having a good time generally.

Operators' Licenses Are Revokable in Bay State

Three Speed Convictions Per Year a Reason—Police Officers Report to Highway Commission of Accidents

By J. T. Sullivan

BOSTON, MASS.—In whom should the power of suspending or revoking licenses to operate a motor car be vested? This question has created considerable interest during the recent legislative sessions where there has been an effort made to alter the law. Where the aim has been to vest this authority in one person, there has been general opposition to such a movement; but, on the other hand, where the power rests with a commission there has been a more general feeling of safety on the part of the motorists. In this state the power to control motor vehicles is vested in the Massachusetts Highway Commission, and has been for some years, and up to the present time there has been no complaint about the way it has handled cases. The general automobile law vests the commission with power to do this work, and under certain sections the law operates automatically in the suspension or revocation of a license. Last year the commission suspended or revoked 546 licenses. This was 186 more than in 1911, when 360 licenses were taken up. Some were given hearings, either by requesting them or by being notified by the commission to appear after the investigators had made their report on a matter.

On the question of speeding the law provides for a speed that is reasonably safe and proper at 20 miles on the highways, 15 miles in thickly settled districts, and 8 miles per hour at intersecting ways or where the view is obstructed.

Limited Fines for Park Speeders

Then there are the park regulations as to speed. If anyone is convicted three times in any calendar year of violating these provisions of the state law it provides: "The commission shall forewith revoke the license of the person so convicted, and no new license shall be issued to such person for at least 30 days after the date of such conviction, nor thereafter except in the discretion of said commission." This section is intended to check the speeding motorists, and as the commission may withhold the license indefinitely, why it can rule the motorist off the road as long as it wants to do so. Last year but one license was suspended, and but two in 1911, which shows that after a person has been convicted once or twice he is very careful not to get caught again because he knows it means a loss of his license, which is more of a deterring factor than the fine.

The fines for such speeding is not more than $25 for first offense—the minimum fine being dropped this year—$25 to $50 for second and $50 to $100 for third offense. In some instances cases may be filed, but there is no imprisonment. As the courts send a record to the commission the motorist cannot dodge it unless he gives another name or commits perjury.

It is under section 20 of the state law that the commission does most of its suspension work. Under one part where it may assign as a reason "operating improperly," a driver may figure in an accident that might be avoided if careful, and when the facts become known the commission gets busy and drops the man's privilege. Last year 152 were dropped and 137 the year before. This section of the law reads:

The commission may suspend or revoke any certificate of registration or any license issued to any person under the provisions of this act, after due hearing, for any cause which it may deem sufficient, and the commission may suspend the license of any operator or chauffeur in its discretion and without a hearing, and may order the license to be delivered to it, whenever it has reason to believe that the holder thereof is an improper or incompetent person to operate motor vehicles, or is operating improperly or so as to endanger the public; and neither the certificate of registration nor the license shall be reissued unless, upon examination or investigation, or after a hearing, the commission determines that the operator or chauffeur should again be permitted to operate.

When that section first went into effect some of those who lost their licenses and had some money simply hired a chauffeur who had a license, and then operated as usual, so the commission had a penalty put in so that now it says:

Any person convicted of operating a motor vehicle in this commonwealth after his license to operate has been suspended or revoked, and any person convicted of operating or causing or permitting any other percon to operate a motor vehicle after the certificate of registration for such vehicle has been suspended or revoked, shall be punished by a fine of not more than $100 or by imprisonment for 10 or by both such fine and imprisonment.

So if a chauffeur lets another operate who is not entitled to he is liable to be fined and imprisoned and also lose his license under the other section of improperly operating, etc.

The reckless driver, and the one driving while intoxicated, is the fellow that gets punished, too, both ways. Policemen of late have been making charges of reckless driving where the charge should have been overspeeding, because under the latter the fines were not as large as the reckless driving. This section of the law has just been amended so that a minimum penalty of 2 weeks has been added now. This includes a number of other things, and automatically revokes the license. It reads:

Whoever upon any way operates an automobile or motor cycle recklessly, or while under the influence of intoxicating liquor, or so that the lives or safety of the public might be endangered, or upon a bet, wager or race, or who operates a motor vehicle for the purpose of making a record and thereby violates any provisions of sections sixteeen and seventeen of this act, or who knowingly goes away without stopping and making himself known after causing injury to any person or property, or who uses a motor vehicle without authority shall be punished by a fine of not more than $200, or by imprisonment for a term of not less than 2 weeks and not more than two years, or by both such fine and imprisonment; and if any person be convicted a second time of operating an automobile while under the influence of intoxicating liquor, he shall be punished by imprisonment for a term of not less than 1 year and not more than 2 years. A conviction of a violation of this section shall be reported forthwith by the court or trial justice to the commission, which shall revoke immediately the license of the person so convicted. If it appears by the records of the commission that the person so convicted is the owner of a motor vehicle, or has exclusive control of any motor vehicles as a manufacturer or dealer, the commission may revoke the certificate of registration of all motor vehicles so exclusively owned or controlled. Whenever any person so convicted appeals, the commission shall suspend forthwith the license of the person so convicted, and shall order the license delivered to it, and shall not reissue said license unless such person is acquitted in the appellate court, or unless the commission in its discretion, after an investigation or upon a hearing, decides to reissue it. No new license or certificate shall be issued by the commission to any person convicted of a violation of this section until after 60 days from the date of such final conviction, nor thereafter except in the discretion of the commission.

Highway Commission Watches Mishaps

This is a very strong provision in the law for it reaches the dealer as well as the owner, and, in fact, the manufacturer, and nothing can be done any way until after 60 days from the final disposition in court. Some drivers used to appeal from lower court sentences and get their licenses back until the section was strengthened by making the suspension date from the first conviction. Last year ninety-nine lost their licenses and forty-one the year before for reckless driving; fifty-six in 1912 and fourteen in 1911 for being intoxicated; and seventeen and eight, respectively, for not stopping after an accident. So that it is pretty hard to dodge the law on the matter.

The highway commission has an investigating force that goes out not only in the Bay State, but into other states and investigates accidents, particularly those resulting in serious injury and death. These investigators have police powers, and when they make a report the commission decides whether or not a hearing is necessary. And upon their reports, too, depend the suspension or revocation of licenses to a great extent. The law requires that

The chief officer of the police department of every city and town, and the chairman of the selectmen of such towns as have no regular police department shall notify the commission forthwith of the particulars of every serious accident which happens within the limits of their respective town or city in which a motor vehicle is involved, and as a result of which a death occurs or appears likely to occur, and shall also, if possible, ascertain the name of the operator of such vehicle and notify the commission of the same. Every such officer, upon the request of the commission, shall demand forthwith the license of any operator and the certificate of registration and number plates or seal of any motor vehicle situated within the limits of the city or town where such officer resides when said license or certificate has been suspended or revoked by the commission, and shall forward the same to the commission. Whenever the death of any person results from any such accident, the commission shall suspend forthwith the license of the operator of the automobile or the certificate of registration of the motor cycle involved in said accident and shall order the said license or certificate to be delivered to it; and the commission shall revoke the same unless, upon investigation or after a hearing, it determines that the accident occurred without serious fault upon the part of said operator or chauffeur. No operator or chauffeur whose license is revoked under the provisions of this section shall be licensed again within six months after the date of the suspension, nor thereafter except in the discretion of the commission.

Under this provision when a death occurs the license is suspended automatically and then the burden of proof is placed on the motorist to prove he was not at fault. Last year 115 licenses were suspended for deaths, and ninety-five the year before.

The law also provides that the judges shall not only send in the abstract records of conviction of motor offenses, but it also requires them to make recommendations relative to licenses when they feel it should be done, as per the following section:

A full record shall be kept by every court and trial justice in this commonwealth of every case in which a person is charged with a violation of any provision of this act or of any other act relative to motor vehicles or to the operation of such vehicles, and an abstract of such record shall be sent forthwith by the court or trial justice to the commission. Said abstracts shall be made upon forms prepared by the commission, and shall include all necessary information as to the parties to the case, the nature of the offence, the date of the hearing, the plea, the judgment and the result; and every such abstract shall be certified by the clerk of the court or by the trial justice as a true abstract of the record of the court. The commission shall keep such records in its main office, and they shall be open to the inspection of any person during reasonable business hours. Courts and trial justices shall, upon their own initiative or upon the request of the commission or its agents, furnish to the commission the details of all particularly flagrant cases which may be heard before them; and they may make such recommendations to the commission as to the suspension or revocation of the licenses and certificates of registration of the persons defendant in such cases as they may deem necessary.

Then there is the Safe Roads Automobile Association and the Highway Safety League, both of which comprise motor owners, who make it a business to do what they can to check reckless and dangerous driving by investigating accidents on their own account and notifying the highway commission of any flagrant cases that come under their notice. Other individual motorists also aid the commission, and the Massachusetts Automobile Operators' Association, comprising more than 500 chauffeurs, also report instances that their members see. All these things help to rid the highways of the reckless drivers. This year, too, the commission has got a law passed whereby motorists from other states come under its jurisdiction and they are amenable to our laws now as well as our own motorists.

Drivers Known in 97 Per Cent. Death Cases

Some evidence of the fact that many drivers do not get away after figuring in fatal accidents is shown by the death statistics, where 135 accidents resulting in 142 deaths were investigated. and out of all 135 accidents in but four instances did the driver get away without being found out. That is a remarkable record. The suspensions for not stopping puts a check to that.

The commission sits every Wednesday on motor cases, and at least one member is on hand, and sometimes two. Occasionally all three members are present if the matter is a serious one. Being empowered to summon witnesses and administer oaths the commission sets as a court. It has the power to pay fees to witnesses similar to the Superior Court. At these hearings everyone has a chance to be heard, and motorists may be represented by counsel. When the case is finished the commission announces its decision, usually the following Saturday, in a statement sent out to the press and also posted in the office of the commission, and there is no appeal from it. Usually a hearing is held within a week or two after an accident when a person asks for one, or about the same length of time after the investigators make their report. These investigators do not lose any time getting busy, for they realize first-hand facts are always best. Here is a specimen statement following the weekly list of hearings:

The following tabulation give some idea of the work and the causes of suspensions and revocations for the past 2 years.

	1911	1912
Action Taken on Formal Complaints After Hearing		
Licenses revoked	4	7
Licenses suspended	11	17
Registration certificate cancelled	1	..
Complaints placed on file	8	9
Complaints dismissed	8	6
Operators cautioned	3	12
Totals	35	51
Suspensions and Revocations		
Licenses revoked	95	190
Licenses suspended	254	325
Licenses cancelled	3	...
Registration certificate sus. or rev.	2	6
Dealers' regis. certificate suspended	1	...
Motor cycle registration suspended	5	14
Motor cycle registration revoked	...	11
Totals	360	546
Suspension and Revocations on Convictions		
Suspension and Revocations on Convictions	75	182
After hearings on formal complaints	15	24
After investigations on which hearings were given in some cases	270	340
Totals	360	546
Causes of Suspensions and Revocations		
Reckless operation	41	99
Under influence of liquor	14	56
Not stopping after accident	8	17
Accidents causing death	95	115
Improper operation	137	152
Three overspeeding convictions	2	1
Operating without owner's permission	24	23
Improper person	21	48
Other offenses	18	35
Totals	360	546
Accidents Resulting in Death		
Registration certif. revoked, owner having no license	1	5
Licenses revoked	15	28
Motor cycle registration revoked	2	..
Licenses suspended, reinstated after investigation and hearing	62	64
Licenses suspended, final hearing pending	14	22
Motorcycle suspended, final hearing pending	1	..
No action, no Mass. license	10	10
No action, operator unknown	..	4
No action, death of operator	5	15
Totals	110	143

Advantages of State Law Enumerated

William D. Sohier, chairman of the Massachusetts Highway Commission, expresses his views on this subject as follows:

"I think this is the only state which is doing very much in this line of work. It takes at least 2 days' time of the board every week reading reports, hearing cases, etc. We have hearings every Wednesday from 9 a. m. to 5 p. m. upon complaints, or as a result of reports made by our investigators, and suspend or revoke licenses. We never revoke without a hearing, except in cases where operators are convicted of reckless driving, etc. We do suspend on report of our investigator.

"I regard the automobile law of this state as a model law in very many respects. For instance, when a man is convicted of any of the major offenses in the courts, like operating while intoxicated, or going away without stopping and making himself known after causing injury to any person or property, or taking a car without authority, causing death, etc., upon receipt of the court record his license is suspended if he appeals and revoked if he does not appeal. It can only be reinstated 60 days thereafter.

"In the case of a fatal accident the license is suspended automatically until we have a chance to investigate the case. Unless the board can certify that the accident happened without serious fault on the part of the operator, the board is obliged to revoke the license and it cannot be restored until after the expiration of 6 months from the date it is revoked.

"We have investigators who immediately look into these matters. At the present time there are five employed, and we will probably appoint more at an early date.

"We also investigate accident cases. When we think the operator was to blame in a serious accident we revoke the license. We suspend the license if it is not a serious case, and notify the operator to come in and let us know why it should not be revoked. You will notice in our report that we have a number of such cases a year. In my judgment it has very much more effect in producing sane operation than any number of small fines imposed by the courts.

"A man in this state has to be very careful not to get convicted of operating recklessly or under the influence of liquor."

The Engineering Digest

Body-Builders in Germany Bid for Importers' Business—Steel Wheels and Versatile Carbureters Made Compulsory for Hard-Service War Trucks

Economical Furnace for Isolated Factories—Advice on the Interpretation of Oil Pressure Gauges—A Trend Toward Simplified Wheel-Drives—Formula for Making Steel Parts Look Like Bronze—Tungsten Recommended for Terminals.

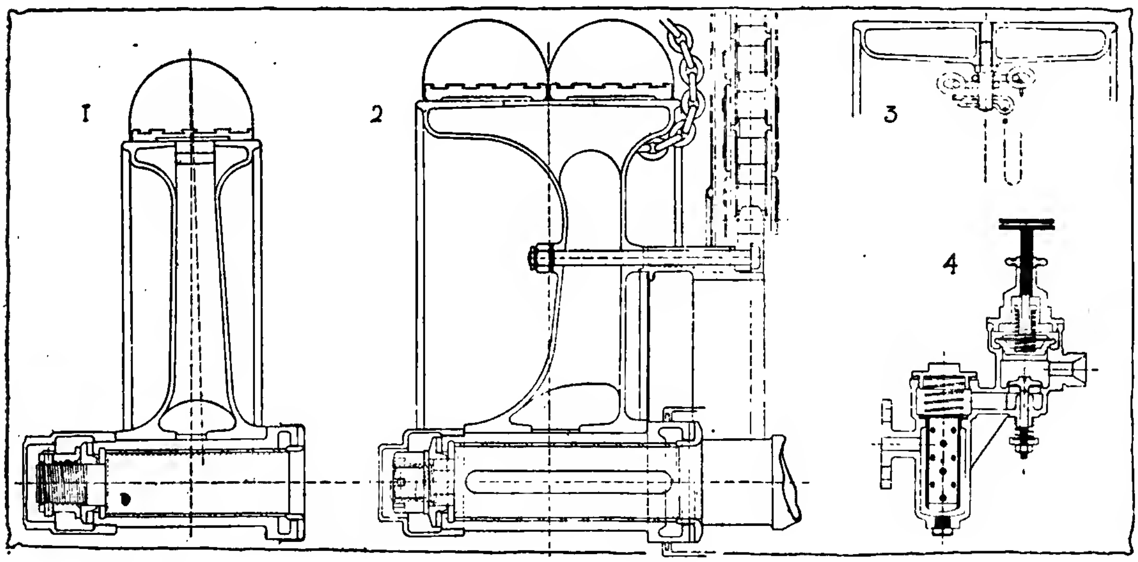
BODIES for Exported Chassis.—A development which may prove of interest to exporters of American cars, either directly or indirectly, transpires in the form of an inquiry from the Prussian Department of Commerce and Trade to the Chamber of Commerce of Berlin. A Prussian manufacturer of automobile bodies applied to the Department for a permit to import foreign-made chassis free of duty, with a view to fitting them with German bodies and then re-exporting the complete vehicles. A similar application had been refused by the Department five years ago, because at that time it seemed inadvisable to facilitate the importation of foreign chassis in competition with those of German make. Now, however, the Department was informed that all German automobile factories were barely able to take care of their orders and also that they were more and more making the bodies for their chassis themselves, with the result that those manufacturers who had made a specialty of body-building had been compelled to reduce their working forces in several instances, especially as orders from abroad for German-made vehicle bodies were only rarely received.

In reply to the inquiry on this subject the Chamber of Commerce replied to the Department that the body-builders and the automobile builders were of opposite opinions. The body-builders reported that automobile manufacturers in France and Italy under the present conditions frequently had their chassis fitted with bodies in Belgium, just because the opportunity to get the work done in Germany was lacking. The granting of the application, and of others of like character, was in their opinion therefore urgently needed. The automobile manufacturers, on the other hand, and especially those who built mainly chassis, feared that foreign chassis-builders perhaps could have bodies built more cheaply in Germany than elsewhere and that the proposed innovation would give them an advantage over German manufacturers of completed cars in the foreign markets. This fear was expressed especially with reference to those American manufacturers who turn out chassis in great numbers.

In one instance it was also mentioned as an objection that foreign concerns would take advantage of the proposed measure to equip their chassis with bodies which have become popular in Germany and would then offer the completed vehicles for sale in the German home market, simply making good the deferred payment of import duty in each case.

The Chamber of Commerce did not consider it proved, however, that foreign builders could not get their chassis equipped with suitable bodies just as cheaply and well in neighboring countries—for example in Belgium—as in Germany, and held that they could therefore probably give German manufacturers the same competition now as under the proposed arrangement. And as the latter would at least benefit the German body-builders, while the present condition did not benefit any German industry, the Chamber of Commerce would recommend that the application be granted. In view of the uncertainty in the commercial development and so as to forestall abuse of the privilege asked for, a proviso should be incorporated in the arrangement, however, calling for the re-export of the imported chassis, together with their German bodies, before the expiration of a stipulated time limit.—From *Automobil-Rundschau*, May 15.

REVISED Requirements for Subsidized German Trucks.—Every year the Prussian ministry of war makes a few changes in the regulations by which those manufacturers of motor trucks must be governed who wish to give their customers the benefit of the subsidy accorded for vehicles which are considered suitable for military transportation service and which are expressly made subject to drafting for maneuvers, mobiliza-



Figs. 1 and 2—Reproduction from scale drawings representing the construction of front and rear cast steel wheels which has been made obligatory for subsidized motor trucks in Germany—giving also their tire equipment

Fig. 3—Section of rear wheel rim between spokes, showing the mode of attachment of traction chains for both rear and front wheels

Fig. 4—Obligatory type of valve for regulating fuel feed pressure derived from the exhaust gases

tion or war. The subsidy consists in a bonus on the purchase amounting to 1,800 mark for a single motor truck and 3,000 mark for a train, composed of one motor truck and one trailer wagon, and in yearly payments of 800 and 1,200 mark, respectively, after the second, third, fourth and fifth years during which the vehicles have been maintained in good order.

The requirements for motor trains have not been changed much since last year, but some features which were declared desirable have been made obligatory in the new set of regulations, the purpose of the army authorities being to standardize the equipment as much and as fast as experience gained during each current year will permit. When definite conclusions are reached with regard to some feature of design or materials, scale drawings embodying these conclusions are made at the experimental department of the army and are provided with annotations from which it can be seen what details still remain optional with the builder. Among the features which have become standardized this year, the wheels are the most important. They must now necessarily be made of steel, and the construction drawings show them as cast steel wheels with hollow spokes and rims. The bearings are plain bronze bushings. In both rear and front wheels, studs for the attachment of traction chains are screwed into the inside of the rim between spokes. Figs. 1 and 2 and 3 show the design with the dimensions and annotations omitted.

Other standardized features are the valve for regulating the pressure feed of the fuel by means of the exhaust gas, which is shown in Fig. 4, the coupling between the motor truck and the trailer (which is similar in design to that of old-fashioned railway car couplings, except that the coupling pin is chained), the connection between the brakes of the truck and those of the trailer, the measurements and nature of tires, which must be of the solid rubber type.

Among other provisions it is noticed that sprags are still required for both vehicles of a train, that the maximum speed of 16 kilometers per hour must be enforced for the empty as well as for the loaded vehicle by means of a governor acting upon the motor at third and fourth speeds, that the service brakes must be water-cooled and the wheel brakes compensated and that the carbureter must be adaptable by adjustment for use with benzol as well as light or heavy gasoline.—From *Der Motorwagen*, May 10.

NEW Recuperating Furnace.—A furnace which seems adapted for a series of work requiring different temperatures, from very low to very high, and in which low-grade fuels may be used, is described by E. Schmatolla in *Der Praktische Maschinenkonstrukteur*. Fig. 8 shows the construction in three sectional views, the second being a vertical section through the low rear portion shown in the plan-section. The pit A, the chamber *f* which serves for the generation of gas and the two heat-recuperators B are built into one piece of masonry. The registers *e* and the sheet-steel slide *t* alone control the direction of the currents of gas, air and flame. The pit A can, according to requirements, be constructed for the heating of stills, vats, crucibles or any other object. When the fireclay plate covering the opening *g* is removed and the registers *e* are closed, the chamber *b* communicates with A, and, if at the same time the slide *t* covers the three canals, *m, n, m*, the gases pass directly from *b* to A by way of *g* and thence along both sides of A through the canals *b*, the recuperators B (which consist in piles of fireclay bricks), the canals *k, l, m*, the slide *t* and the canal *n* to the flue *o*.

When the furnace is started and so long as it is desired to work at low temperatures, only a thin layer of fuel is placed upon the grate in G, and the flames pass by the route mentioned. In order to heat the flue and promote the draft at the beginning, the fireplace can also be connected directly with the flue. Then, if it is desired to increase the temperature progressively fuel is added by successive stages and, likewise, the access of air coming in over the registers *e* is gradually increased; the flame forms in the pit A and passes to the flue by way of the recuperators where the heat of the hot gases is absorbed by the firebricks.

When the slide *t* becomes very hot, or, in other words, when useful heat is escaping, it is better to reverse the direction of the flame and utilize the exhaust heat for preheating the air used for combustion. To this end, the opening *g* is closed, one of the registers *e* (the one to the left in the illustration; not lettered) is opened and the slide *t* is pushed to one side, so that it covers only the openings *m* and *n*, leaving the other opening *m* (to the left) free to permit the arrival of air. The air now comes in through the canal *l-k* to the left, passes through the recuperator B to the left, absorbs the heat there stored and arrives strongly heated by way of canal *b* to A. Before entering, it mixes with the generator gas coming from the canals *c, d, h, f* to the left and produces a very hot flame which traverses the pit A. The waste gases pass through the other recuperator and reach the flue by way of *k, l, m, t* and *n*.

When, after some time, the air for combustion has absorbed all the heat in the recuperator to the left, the direction of the gas currents is again changed by closing register *e* on the left side, opening the other register *e* and pushing the slide *t* to the left.

By this system the temperature can be raised practically to the maximum obtainable with atmospheric air. With very slight changes the construction of the furnace can be adapted for operation with producer gas or natural gas as fuel.—From *Revue de Métallurgie*, May.

READING the Oil Pressure Gauge.—Among the more or less practical hints offered to motor car users by writers for the European press many are double-edged, being more eloquent in pointing out shortcomings which ought to be remedied by the makers of cars and accessories than in designating the best method for getting along with things as they are. The advice given frequently proves more than was intended, and in other cases it suggests a condition which does not exist, as when repairs are described which never should be made, because they cost more than replacements of parts and fail to bring about the alloy-steel strength which is required. Reflections of this order, from which the principal upshot is a sharp realization of the advantages to be gained by making such judicious selections from among the cars and accessories which the market affords that the troubles for which remedies are offered will not arise, are suggested in this instance by the complicated advice on the reading of oil pressure gauges which an expert presents to the French automobile public, and from which the first inference would be that certain improvements of these gauges might be more easily accomplished than the training of the public to the proper use of those to which the writer refers. As the subject is not often treated, the advice is repro-

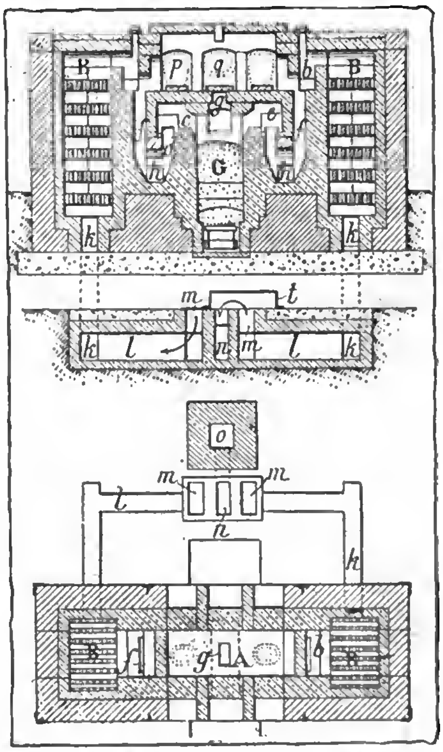


Fig. 8—New recuperating furnace—an element in factory economy and convenience

duced in full—the translation being almost verbatim—as follows:

The hand of the oil pressure gauge does not only indicate the pressure existing in the oil ducts; it is not only the movements of the hand which should be observed but also their nature.

Sometimes, in the morning, when the car is started, the hand rises to the top of the dial. Then, after a few jumps, it suddenly falls back to zero. It is because the oil has thickened, and, though it has been sent into the organs of the motor, it does not return fast enough for feeding the pump; it is accumulated, for example, in front of a filter. The motor should therefore be allowed to turn over slowly.

If this incident occurs regularly, a more fluid oil should be used. If, in spite of all care, the pump frequently runs idle, the filter placed at the entrance to the pump must be very much fouled and should be cleaned.

On the road, the indicator hand remains nearly stationary. If it drops low when the car is slowed up, all is well.

If the hand remains at a high figure throughout all speed variations of the motor, this indicates that the oil is too heavy and meets too great resistance to its circulation. One cannot know in that case whether the oil really passes through the ducts in the crankshaft or only through the safety valve.

If after one or two hours of travelling, and while the car is running at a uniform gait, the hand begins to swerve irregularly, slightly at first but soon fitfully, falling to zero and then again rising, the cause is either an obstruction or lack of oil. A glance at the level will tell which.

It happens that the hand drops definitively whatever quantity of oil the pump has to work with, and if the explanation is not to be sought in a poor quality of oil which loses all its viscosity when heated, the reason is either that the safety valve is not held to its seat by its spring and therefore acts as a bypass or that a tube is bursted.

When the hand rises unusually high during normal operation of the car, some impurity must have clogged the circuit, and there is danger of injuring the tubing. One should stop and investigate. Perhaps only the valve has become glued to its seat by reason of too much resin in the oil. In this case, clean the valve with gasoline, empty the oil reservoir and refill it.

Pressure gauges are sometimes blamed for being flighty and unreliable. It is especially charged that the oil tube leading to it is liable to leak. Many owners of cars would in fact like to have the indicator hand of the dial connected by flexible cable to a piston located in the crankcase, rather than by the column of liquid in the tube.

Inaction of the pressure gauge does not always indicate a disturbance in the circulation of the oil, but if a doubt arises because the hand does not move it is always easy to verify the condition. In all motors there is, in some form, a screw or plug closing an entrance to the circulation conduit. Remove it, while the motor is running, and, if the oil gushes out, the circulation is established.

From this enumeration of possible contingencies it is plain that in case of trouble the fault is always to be found either with the filter or with the safety valve. The remedy is obvious: Demand that these organs shall be very accessible. For, all that is required is that they should be cleaned once in a while.—From *Omnia*, April 5.

—

FLOATING Wheel-Drive Losing in France.—Whether it be due to improvement in the materials used for wheel shafts, to the increasing popularity of double ball-bearings or to a desire for simpler and more economical construction forms and readier removability of wheels, the number of new models, among automobiles rated as high class, in France in which the driving wheels are supported on the end of the wheel shafts, seems to be increasing. As examples of the trend there are shown in Figs. 5, 6 and 7 the axle-ends in the latest models of Darracq, Vinot-Déguingand and Chenard-Walcker cars. In the latter the drive is effected by a special shaft to a gear ring inside of the brake drum, so that the floating type is out of question—a construction adopted by this conservative firm many years ago and continued despite contrary dictates of the fashions for pleasure cars. The new Darracq model is one fitted with poppet-valve motor, the concern having apparently been compelled to abandon the idea of relying on its rotary-valve motor alone, in view of the disastrous showing of its last annual balance sheet.—Illustrations from *Omnia* and *La Vie Automobile*.

—

SUBSTITUTES for Platinum.—Palladium and tantalum have been proposed as substitutes for platinum for electric contacts and terminals, both mainly on the ground of economy. According to C. G. Fink in *Revue Electrique*, tungsten is more acceptable than either, being superior to platinum in all the applications where continued exposure to very high temperatures is involved and costing only about twice as much as nickel in its usual commercial form and about $25 per kilogram when refined to purity. It has been shown that pyrometers equipped with tungsten-molybdenum couples outlasted—so far as the terminals were concerned—those equipped with platinum and platinum-rhodium, and in small electric furnaces for laboratory use tungsten has been used in the form of thin wire for wrapping the porcelain tube and also for the tube itself, in both cases rendering it practicable to generate and maintain a temperature of 1800 degrees C.—From *Electrochemische Zeitschrift*, May.

—

BRONZE Patina for Steel Parts.—After the part has been thoroughly cleaned it is exposed for a few minutes to the action of the vapors of a mixture of HCl and HNO_3 in equal parts, whereafter it is heated toward 300 degrees C. until the bronze-like shade appears. After cooling, the piece is coated lightly with paraffine or vaseline and is then again heated until the fatty matter is decomposed. To deepen the shade, the operation can be repeated. Pretty and unchangeable shades are obtained by this process. By a final exposure to the vapors of *aqua regia* (same mixture as above) a clear brown tint is produced, while a yellow tint can be obtained by adding acetic acid to the original mixture.—From *La Technique Moderne*, May 15.

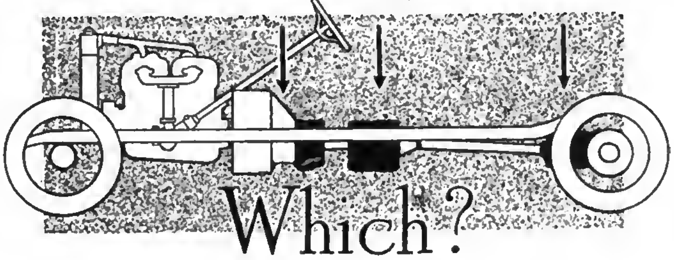
The Engineers' Forum

Gearbox Location



Which?

Part VI.

Another Defense of the Rear Axle as a Gearbox Location

AUTOMOBILE engineers are still manifesting their interest in the question of gearbox location which had its beginning in an article published in THE AUTOMOBILE for April 17. This has been more thoroughly threshed out in these columns by the leading engineers of the country than any other question of design yet brought to the attention of the automobile public. Other topics are also taken up by the engineers in this week's issue of THE AUTOMOBILE, that of the rating of motor horsepower by the manufacturers and by the state registration and taxing officials, and that of tires, whether solid or pneumatic, for light delivery wagons.

Another important question of construction which will be taken up in the Engineers' Forum in the near future is that of automobile springs. Much interest is being taken by both engineers and automobile owners in the article entitled Defects in Springs, which appeared in THE AUTOMOBILE for May 29, and many of them are expressing their views on the subject.

Rear Axle Weight Is Not Important—Bates.

HYDE PARK, MASS.—Editor THE AUTOMOBILE:—After reading the arguments for and against the rear axle gearbox, the only point that seems worthy of consideration is the fact that shifting rods are employed to shift the gears. This should occasion no trouble if the design is carefully worked out in regard to location of centers of oscillation, so as not to cause a pull on shifter rods and levers due to up and down movement of the frame over rough roads.

In regard to extra unsprung weight on the rear tires, there may be a basis for argument on this point, but it seems to be more theoretical than practical, as we have proven by test that our rear axle gearset, torque tube, etc., weighs 54 pounds more than another rear axle of very popular make used on our type of car. If the rear axle weight is such an important consideration, we all should go back to the propeller shaft brakes, cut down the size of the rear wheel brakes, and save every possible ounce, but in practice, our cars of 3,200 pounds with 4-inch tires show an average mileage of 4,500 to 5,000 miles, and quite a number from 6,000 to 7,000 miles, while with 4.5-inch tires, our owners have run, in a number of cases, from 8,000 to 10,000 miles, so that it seems that this point is more theoretical than practical.

Now in regard to the argument that the rear axle gearset is cheaper for the manufacturer. Certainly what is cheaper in the way of simplicity for the manufacturer should be to the advantage of the buyer. If it costs less to manufacture and assemble, certainly when the tire comes for repairs and adjustment, and the time will certainly come, this point must work to the advantage of the owner, as it is a matter only of releasing torque tube ball housing, spring seats, and brake rods, in case the transmission is to come out, and the whole job is ready to do whatever is necessary, a matter of perhaps half an hour's work.

In regard to accessibility for inspection, we find that it is no more difficult to remove tonneau floor boards than the floor boards in front.

In regard to poor weight distribution, we find that our touring cars weigh 20 pounds more on the rear end than the front, so there cannot be any great argument there, while the center of gravity of our transmission is 4 inches lower than with the amidship or motor unit construction, which is certainly a point in our favor.

Then in regard to noise, everybody will admit without argument that the rear axle type is superior to other types in this respect.

In regard to poor riding, this point seems to be more a matter of spring suspension than anything else, as I have seen very good and very bad riding cars of all constructions, and have seen cars of rear axle transmission type ride as well as cars of the other types.

In regard to multiplicity of parts, the rear axle unit has, especially in our construction, no parts such as radius rods, torsion rods, extra universals, etc., to become loose and rattle, such as are ordinarily found in amidship construction, which of course means less wear and tear on the nerves of the owner, and his pocketbook.

In the matter of alignment, this point requires no argument whatever, as the advantage is altogether with the rear axle and motor unit type.

In regard to its being fit for use only on cars of low horsepower, we all remember this same argument upon the advent of the shaft drive; time has proven this construction suitable for any horsepower.

To the mind of the writer, there seems to be no good argument for the amidship transmission, the question in mind being whether the motor unit is better than the rear axle unit, and we have come to the conclusion that it should be the latter.—C. T. BATES, Engineer, Lenox Motor Car Co., Inc.

Thinks All Types Satisfactory—Macksey.

EAST ORANGE, N. J.—Editor THE AUTOMOBILE:—In discussions recently published in THE AUTOMOBILE I have noticed that each location of the gearbox had its good and bad points equally distributed. I noticed that one manufacturer claims that the placing of the gearbox amidships will distribute the weight more evenly so that an undue proportion is not put on the front axle or on the rear axle, to some extent lessening the liability of skidding, while another says that the gearbox placed on the rear axle will give the rear tires more traction, also lessening skidding. Then, too, the unit with the motor has its advantage in that it is most simple and easily accessible. Most of the engineers agree that the weight of the car has a great deal to do with the placing of the gearbox, that the unit with the motor belongs to the small cars. there being less weight; that the gearset mounted amidship should be in a high-powered car; and the gearset as a unit with the rear axle should be used where quietness of operation is wanted and a wide range of choice for the engineer in the location of his control levers which may be set practically anywhere to conform to his particular idea of accessibility with this type of gearbox.—JAMES F. MACKSEY.

Automobiles Pay Enough Taxes Now—Klinger.

DAYTON, O.—Editor THE AUTOMOBILE:—I certainly believe the tendency within the last few years of all manufacturers has been to rate their motors under absolutely ideal block conditions. The motors, it is true, will show considerably greater horsepower under these conditions than they will when actually applied to a chassis and operated on the road. As a matter of fact, it is very seldom that the full horsepower of the engine which it is capable of producing in the chassis is utilized in road service, and our impression is that fully 95 per cent. of the time motors are operated only at from 15 per cent. to 20 per cent. of their rated capacity, and we further believe that there is a tendency in all automobile plants toward a reduction instead of a further increase in the size of motors.

I should very much regret to see any action taken which would increase the tax levy of various states on the automobile, not for its influence directly on the trade, but as a matter of justice, as the average automobile owner certainly contributes his share to the various state expenses.—P. W. KLINGER, Speedwell Motor Car Co.

S. A. E. Rating Is Accurate Enough—Feilicke.

INDIANAPOLIS, IND.—Editor THE AUTOMOBILE:—We agree with you that the present S. A. E. or A. L. A. M. horsepower rating is accurate enough to be taken as a basis for taxation purposes.—KARL FEILCKE.—Motor Car Mfg. Co.

A Consistent Motor Rating Needed—Power.

SYRACUSE, N. Y.—Editor THE AUTOMOBILE:—The formula for horsepower of motors other than the present S. A. E. rating should have a value by which a comparison of different motors can be made, and also furnish a basis of taxation.

The varying bores and strokes, together with other factors, such as valve design, balance, weight of reciprocating mass, etc., have a major influence upon the horsepower. If there is to be any consistency in motor rating, it should be based upon the volumetric displacement of the pistons and a piston speed in excess of 1,000 feet per minute. This would give all reputable manufacturers, who are exercising their skill toward the production of a motor of higher horsepower for the same or less weight, of higher fuel economy and of staying qualities, a deservable higher rating—as it obtains today.

Our 4 1-2-inch by 5-inch motor develops 12 per cent. more power at 1,000 feet per minute piston speed than the S. A. E. rating, while the maximum horsepower is developed at a piston speed of over 1,600 feet per minute.—M. POWER, Engineer, H. A. Moyer.

S. A. E. Formula Is Satisfactory—Lambert.

ANDERSON, IND.—Editor THE AUTOMOBILE:—I am of the opinion that the A. L. A. M. rating is nearer right than any other rule for figuring horsepower of motors.—J. W. LAMBERT, Buckeye Mfg. Co.

Pneumatics Best for Delivery Work—Stewart

BUFFALO, N. Y.—Editor THE AUTOMOBILE:—One of the most important problems that confronts the designer of light delivery trucks is the question of pneumatic tires or solid tires. In an effort to eliminate tire troubles some designers of light weight delivery cars have adopted the obvious expedient of using solid tires. Without exception the results have been most unsatisfactory.

Even where spring wheels of various types have been adopted the use of solid tires has proven a serious mistake.

There are three chief disadvantages to the solid tire for use on light delivery cars—first, vibration; second, tire wear; third, increased gasoline consumption. The light weight delivery car must necessarily be operated at a speed of from 20 to 25 miles an hour in order to accomplish the work for which it is designed. At this speed, no matter how well the car is designed, the constant jarring of delivery service will very soon result in mechanical trouble. This simply cannot be avoided.

Some designers make the mistake of building their truck parts several times heavier than necessary, thinking thereby to make it possible to use solid tires. This, however, is a fallacy, for the excess weight they add causes additional strain.

The second disadvantage is that a solid tire will heat up and deteriorate rapidly if the speed exceeds 18 miles an hour. I do not believe there is a tire company in America that will give a guarantee on solid or cushion tires if they know that the speed of the vehicle will exceed 18 or 20 miles an hour at any time.

The third disadvantage is increased fuel consumption. From our past experimental work we feel safe in stating that the gasoline consumption will be 25 to 30 per cent. more with solid tires than with pneumatic.

With demountable rims the truck user has little to fear from the chance of punctures. A tire can be replaced in a few minutes and the truck is then again in service. But mechanical trouble resulting from the use of solid tires requires hours for repair during which time the car is out of service—to say nothing of the expense of mechanical repairs.

Experienced truck users have learned the fallacy of the solid tires. John Wanamaker has been using motor trucks probably longer than any concern in America. At first Wanamaker demanded solid tires; now he will not buy a delivery rig with anything bue pneumatic tires. He has learned by experience.

The New York *Herald* some years ago bought several Renault trucks. When the first pneumatic tires wore out they replaced them with solid tires. From that time on records show that the trucks were in the repair shop a considerable part of the time. Noting this, the *Herald* people finally replaced the solid tires with pneumatic and at once the trucks resumed their former satisfactory service.

All this is true of every other concern that has had experience with motor delivery wagons. The little bit saved in tires is spent three or four times over in mechanical upkeep.

In my opinion it will be only a year or so till all prudent buyers of light delivery trucks will demand pneumatic tires for their own protection. I should be glad to hear the opinion of other engineers on this important subject.—R. G. STEWART, vice-president and chief engineer, Stewart Motor Corporation.

Make Accessibility Indispensable—Day.

BINGHAMTON, N. Y.—Editor THE AUTOMOBILE:—Although I am not an automobile engineer, I have owned and driven cars of various makes and models for several years and one point has always struck me very forcibly. This is the secondary consideration given by many engineers to the important feature of accessibility and demountability of parts.

With a large number of the cars now on the market, and particularly with the smaller types of cars, when one has trouble with the motor or its adjustments, the suspension, the cooling system, the gearbox or transmission line, or, in fact, almost any part of the car whatever, he has to dig around in the most inaccessible places possible to imagine and generally with a disastrous effect on his clothes. His temper, of course, is usually affected, too, and sometimes his language.

It seems to me that, while the leading engineers are trying to make accessibility a salient selling feature of their cars, they do not go into the matter thoroughly enough to get real results. They had apparently made considerable headway last year when suddenly the electric starting and lighting stampede began and threw most of them off their mental balance, from the mechanical mix-ups into which they converted their motors, so recently worked up into clean designs. Since that time most of them have been trying to recover the lost ground, with varying success.

In my opinion, the only element required to bring about a much more considerate style of design by the engineers is the pressure of public opinion to the effect that accessibility is indispensable in a car. I would like to see some of the engineers' views on this subject published in The Engineers' Forum.—LEE DAY.

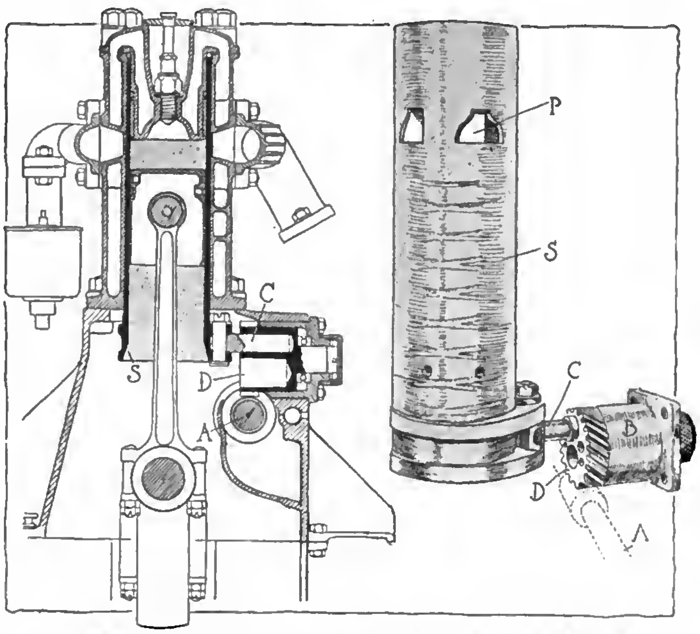
Sleeve-valve Car Makes 14-hour Record

LONDON, ENG.—A remarkable track performance of great interest to automobile engineers in general and non-poppet enthusiasts in particular has recently been made at Brooklands, in which a car with a sleeve-valve engine succeeded in covering 1,016 miles 437 yards in 14 hours at an average speed of 72.52 miles per hour, constituting a new world's record for that time. The triumphant car is an Argyll, a popular British make, and one of the most successful exponents of the single-sleeve school of slide-valve operation.

The record for 14 hours which has been struck off by this latest performance is an old standing one of 6 years by S. F. Edge, who made 980 miles 480 yards on a Napier in 1907.

Much of the value and importance of the test is owing to the fact that it is the first officially observed track trial of any appreciable length of a slide-valve engine, although bench tests and road races in which another type of slide valve has participated have demonstrated the practical value of the double sleeve valve.

The Argyll chassis used was of the standard type as sold on the market, with the exception of two minor alterations which, however, do not detract in any way from the lessons to be learned from the trial. These were the lightening of some of the reciprocating parts and the substitution of a gear ratio more suited to performance on the track for that on the standard model. The engine dimensions are 3.5 inches stroke by 5.12 inches stroke. A Zenith carbureter was used and Bosch ignition. The final drive at the rear axle is by overhead worm, the gear ratio for this test being 3.25 to 1. The body was a single seater of streamline form with a pointed tail, and the total weight 2,726 pounds.



Figs. 1 and 2—Section of Argyll single-sleeve slide-valve engine with detail view, showing sleeve and operating mechanism

No engine trouble of any kind developed during the run, the only stops throughout the entire 14 hours being either for the replacement of tires or the changing of drivers. The wheel was taken alternately in 3-hour shifts by W. G. Scott, works manager of the Argyll factory in Scotland, and L. G. Hornsted, a well-known racing driver.

A remarkable feature of the trial was the regularity of the speed, which was maintained at between 72 and 73 miles per hour throughout the whole performance. The lowest speed took place during the fourth hour, when a distance of 72.04 miles was covered. This speed was well within the power capabilities of the car. The arrangements for the event were very complete and well thought out. At every lap the driver was informed by means of large figures on a board the speed of his previous lap so that he was able to gauge his driving accordingly. Further, there was a system of signals to denote whether the exhaust was smoking or not so as to facilitate the lubrication problem for the driver. A staff of well-trained men were stationed at the replenishment depot and an idea of their speed, even in these days of red-hot work in the tire pits during the big races, can be gathered from the fact that in one of the stops, which was timed to last only 1 minute 41 seconds, all four wheels were changed, gasoline and oil tanks filled, the engine crankcase drained and refilled, and the car restarted. Castor oil was the lubricant used for the rear axle, the casing being kept always filled. At the end of the run the worm gear casing was found to be no warmer than would be the case with bevel gear.

A brief description of the Argyll sleeve valve may be of interest. Fig. 1 shows a transverse section in which the sleeve S will be noted, occupying the annular space between the piston and the cylinder wall. Its action is peculiar in that the motion imparted to it is not merely up and down but is also partly rotational. This will be made clear by reference to Fig. 2, which shows the sleeve and its operating mechanism detached from the engine. The reciprocation of the sleeve is effected by the action of a small crank C which has a sliding fit in the rotating member D. This latter is carried in the bearing B, which is bolted to the crank casing wall. The operating shaft A, which is equivalent to and occupies the same position as the camshaft in the poppet-valve type of engine, is provided with four worms or skew gears, one at each cylinder, which engage with teeth on the rotating member D, driving it at half the speed of the crankshaft. This reduction takes place at the skew gearing, the camshaft itself running at the same speed as the engine shaft by silent chain.

Two revolutions of the engine shaft, therefore, cause a single revolution of the actuating crank C, which in turn imparts such a motion to the sleeve that any one point on its outer surface will have traveled through an elliptical path on the cylinder wall.

This peculiar motion is the fundamental principle of the Argyll valve. It permits a complete register of opening of the valve port P with the corresponding ports in the cylinder wall while the sleeve is traveling in one direction and a complete closing on the opposite stroke. As the sleeve descends, exhaust is opened and during the return stroke the inlet ports open. This cannot be accomplished by a single up and down stroke of a sleeve with the ordinary straight reciprocating motion, where both valves would necessarily be opened twice.

The method of final drive renders the result doubly interesting, for the amount of information regarding the efficiency of worm drive as against bevel is scanty and difficult to obtain. In any case no better way of bringing forcibly to mind the practicality of the worm drive as a means of transmitting the power of the engine to the road wheels could be devised than this establishment of a record in which the worm played a part.

In the Argyll cars the drive is practically in a horizontal straight line from the engine to the rear axle, the worm being located over the worm wheel. The high efficiency of this type of drive with its almost total elimination of work wasted at the universals is generally recognized.

The designer of the Argyll car is a Frenchman, M. Perrot, and it was first introduced to the automobile public at the Olympia exhibition in London at the latter end of 1911.

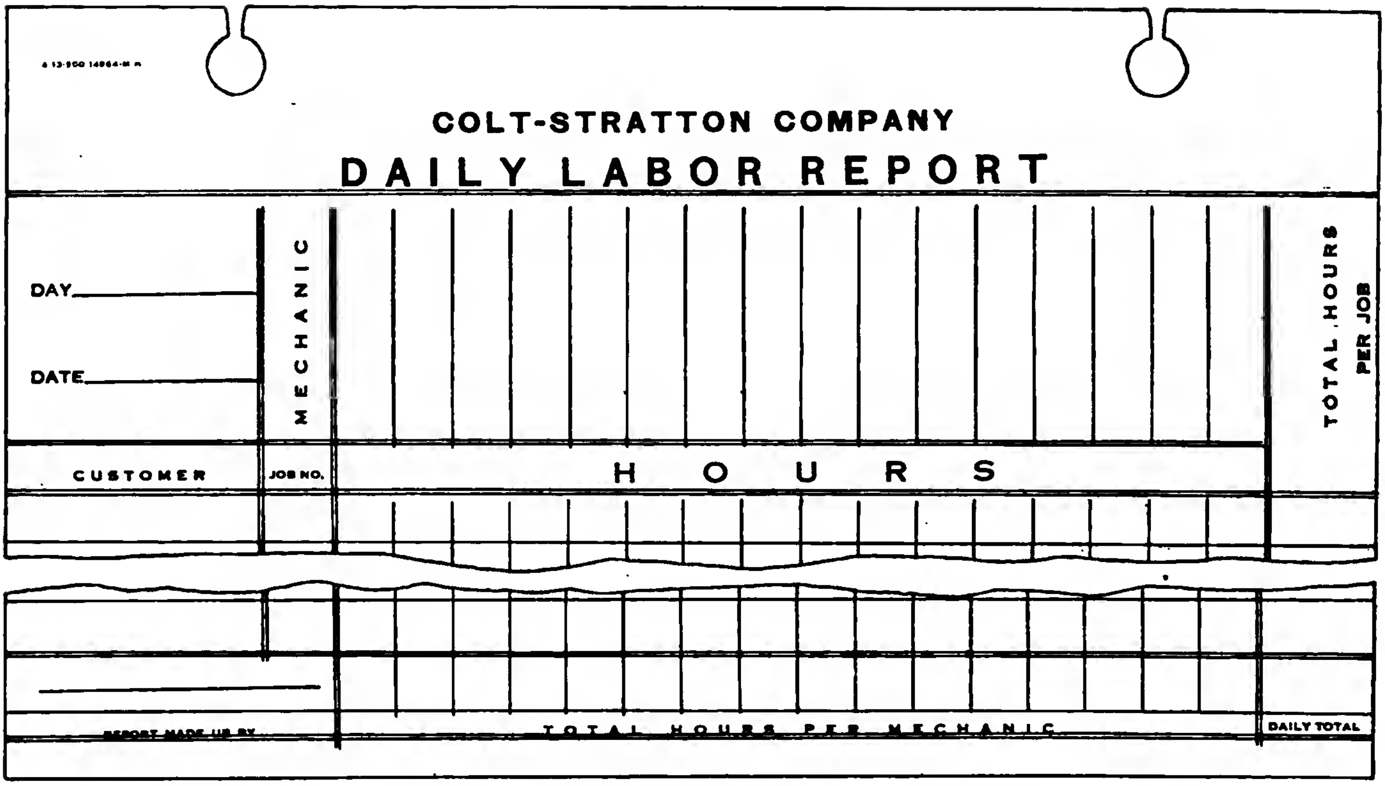


Fig. 1—Daily labor summary, which shows the distribution of the skilled labor used on various job orders

Service System of New York Cole Dealers

Including Twenty Forms Among Which a Number Are Original—Daily Labor Report a Feature

IMPROVEMENT of car construction is only half of the developments made by the industry. The other half consists in the evolution of the means for prolonging the life of the car and increasing serviceability, which means are numerous and of varying efficacy. Among them good roads and prompt, efficient service are of leading importance. To use an illustration, let us compare an automobile to a set of teeth which is gradually depreciated by its work until it is all worn out. If the comparison is carried further, good roads correspond to the proper food which is mechanically and chemically least harmful to the teeth—the automobile; while the prompt attention of the decaying teeth, by means of which they may be saved and their life and service prolonged, finds a parallel in repair work made while the troubles growing in the car are still in their incipient stage. This simple comparison makes it clear that prompt service is a great advantage and necessarily appreciated by the user of a car, and that on this account it is the duty of the manufacturer toward himself and his customer to conduct his service departments as efficiently and economically as he can, which can only be done if all details of the organization are known to the heads thereof.

Complete service systems for automobile agencies and branches are now becoming an everyday thing and, although most of the systems are quite similar in general ways they differ in more than one particular. The latter fact is caused by the differences in experiences of the men who design the system and the blanks used in connection with it and as a further consequence there is hardly a system which does not include several original blanks, or, if they are not original throughout, such that are new in more than óne respect. By this is meant that a given form is either designed in a specially advantageous way to serve its purpose or that it provides for the recording of additional information as compared with blanks used for the same purpose up to the time of designing the blank.

One of the latest service systems which have been introduced in New York City is that of the Colt-Stratton Co., Cole dealers. The forms used in this system are here described and illustrated and the readers interested will find, by comparing these forms with systems already described in THE AUTOMOBILE, that the Cole

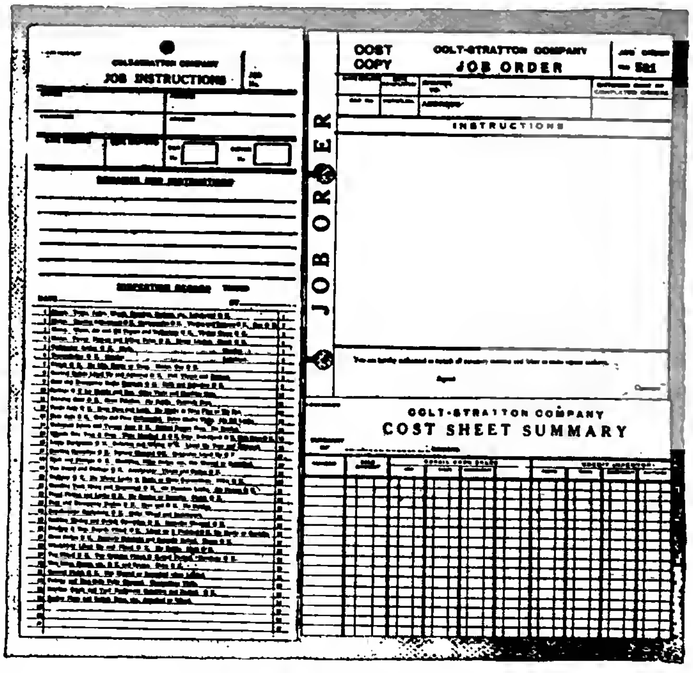

Fig. 2—Instruction tag attached to car. Fig. 3—Job order form. Fig. 4—Orders summary sheet

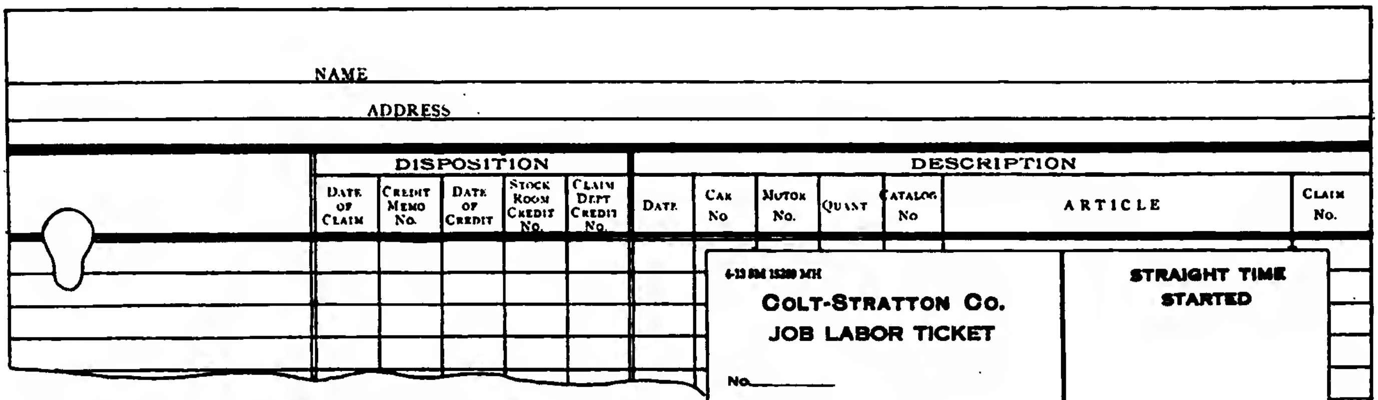

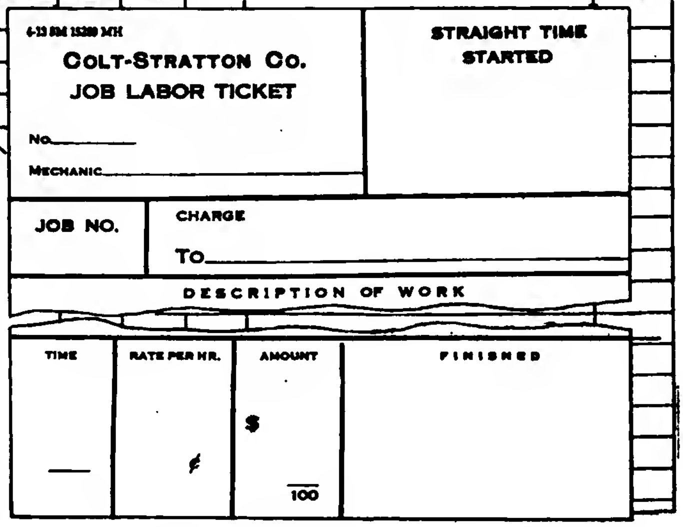

Fig. 5—Record of material received from customers and dealers. Fig. 6—Job-time record card

scheme is original in many ways and therefore worth describing.

1. **Job Order**—The first form, Fig. 3, is 8.5 by 11 inches, one copy being printed on yellow paper and one on white, the yellow copy being marked charge copy and the other cost copy. Both are numbered with the same number, coming in pads which form series. The order is made out in duplicate, that is to say, on both forms when the customer brings in the car. He signs the order for the cars turned over to the shop.

2. **Job Instruction Tag**—Fig. 2 shows the tag used for giving the shop men instructions of the work to be done on the car, for inspecting the same after repairs are completed and for checking the equipment and accessories on the car when it is taken over and before it is delivered. The accessory checking spaces are printed on the reverse of the form, not shown here. The tag, as here illustrated, is 6.5 by 14 inches, printed black on yellow cardboard and fitted with eyelet for the purpose of attaching the card to the steering wheel of the automobile. The upper half of the side here shown is filled out in the office of the department superintendent before the car and the tag go into the shop, while the accessory checking space is first filled out when the car is taken over by the shop and the removable parts are taken off and placed in the locker, marked with the car owner's name and the number of the automobile.

3. **Job Labor Ticket**—The Colt-Stratton Co. uses square labels on thin paper for recording time spent by a man at any

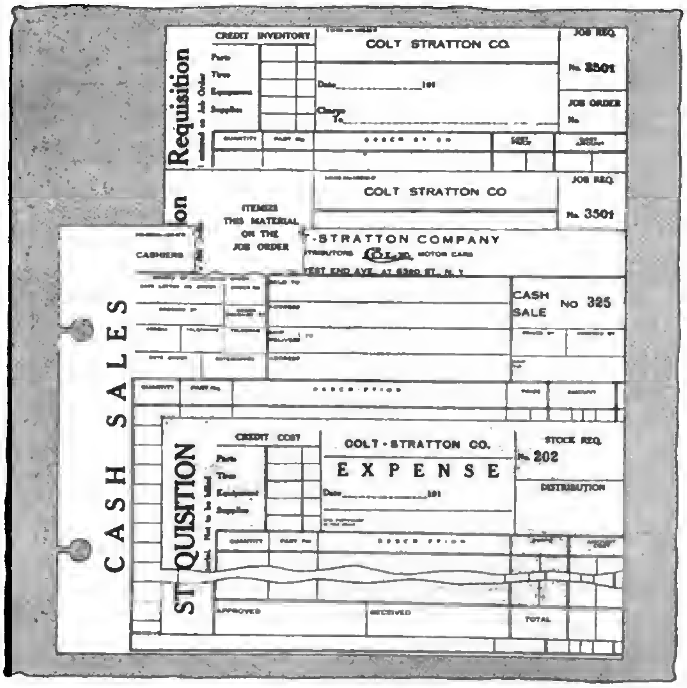

Fig. 7—Requisition on job orders. Fig. 8—Cash sales requisition. Fig. 9—Non-job requisition

given job, this ticket being supplementary to the weekly clock card. Fig. 6 shows the job ticket used during day time, which has spaces for the number and name of the workman, the job number, the party to whom the work is to be charged, the description of the work, time consumed, the wage rate, the total wages due for the work and the time of starting and finishing the job. This ticket is white; if overtime work is done a pink ticket is used which is printed exactly like the white, save for the words overtime in place of straight time. These tickets are turned over to the shop foreman in the evening when the workman leaves the place, being delivered by him to the office, where the payroll is made up.

4. **Daily Labor Report**—The times spent by the workmen on the various jobs during a day are compiled and recorded on the daily report, Fig. 1, which is printed on tan paper, 10.5 by 14 inches, the names of the various workers are entered adjacent to each other at the top portion of the sheet, while the names of the customers are given in the first column of the paper. The spaces formed by the intersection of the horizontal and vertical columns are filled out with the time spent by the mechanic on the car of the customer. The last column at the right of the sheet gives the total amount of time spent on the various jobs, while the last line at the bottom contains the total hours spent by each workman. The clerk who makes up this report from the time tickets sign it before turning it over to the book-keeper.

5. **Job Order Requisition**—Whenever material is needed in the shop for the execution of repair work, the man requiring the material fills out a requisition, Fig. 7, which is 9 by 6 inches, and comes with a duplicate bearing the same number. The original is white and the upper left corner is printed with a space marked credit inventory on which material to be credited to the customer are recorded. In filling out this form the workmen dates it, fills in the name of the car owner, the number of the job order and particulars referring to the material that he needs. Before the latter is drawn from the stockroom the foreman O. K.s the requisition and its yellow duplicate, both being taken to the stockroom, where they are retained after the material has been given out and signed for on the two copies by the person receiving it. At the end of the day the white copy is sent into the office, while the yellow remains with the stockroom foreman to be filed.

6. **Expense Stock Requisition**—Fig. 9 shows a requisition

which is used when material is drawn from the stockroom required for any purpose except a job order. This form is of the same size as Figs. 7 and 8, but is printed on green paper and comes in pads, blanks being consecutively numbered.

7. **Cash Sales Record**—If parts are bought from the Colt-Stratton Co. a special requisition is made out, Fig. 8, which is 11 by 8.5 inches. The original is printed on white paper and is destined for the cashier; a pink duplicate is delivered to the customer when the order is taken; a yellow triplicate goes to the service department office and the quadruplicate, printed on light tan cardboard, goes to the stockroom where it is filed after the goods have been given out. As Fig. 8 shows, this blank affords space for recording a mass of valuable information.

8. **Bill**—Fig. 12, bill used by the Cole dealers in New York City, the duplicate differing only by the distribution space printed in the upper left corner. This space is used to give a comprehensive statement of the distribution of the amount appearing on the bill and what they are for. By striking out the W and R mark, a record is made of whether the goods were sold retail or wholesale. In all other respects this bill is designed along strictly conventional lines. Originals and duplicates are numbered.

9. **Defective Parts Return Record**—When defective parts are returned to the company the office clerk receiving them fills out a record, Fig. 14, which is printed red on white paper, with a duplicate on pink and a triplicate on yellow paper. The original copy is kept by the accounting department, the duplicate is given to the customer or his representative delivering the parts, and the triplicate accompanies the latter to the stockroom. The claim department, which receives the goods when they are brought in, puts down all the data referring to the car on which the parts were used and makes out a credit note to the customer which is numbered, the number being recorded on the form, Fig. 14.

10. **Return to Stock Form**—If new parts or materials drawn from the stockroom for the purpose of a repair job are returned to it without having been used, a form, Fig. 13, which is of the same size as Fig. 14, is made out. The original is printed on white paper and the duplicate on yellow, being filed by the accounting department and the stockroom respectively. This form is also used if parts have been sold to a customer and are returned without having been used. In any case, the date on which the parts were issued and the order on which this was done as well as particulars referring to the party to receive them and to the nature and quantity of the material are recorded on this form. The stockroom clerk signs both copies of the form before the material is put back in the stock.

11. **Credit Memorandum**—Whenever a customer returns parts he is given the credit referred to above, which is illustrated in Fig. 15. The copy given to the customer, however, is printed with the name of the company on top of the paper and is 9.25 by 8.5 inches, while a duplicate, here illustrated, is 11 by 8.5 inches. Both copies, however, are printed on pink paper. The copy here shown is filed by the claim department, which latter takes the matter up with the factory.

12. **Cost Sheet Summary**—It is of special value to the company to have a particular record form for compiling every day the cash sales made and the credits given for return parts. Fig. 4 shows this blank, which is 11 by 8.5 inches, printed on white paper and punched so that it may be held in the binder together with records made in the past. On this form the number of order or the credit memorandum is entered and along with it the amount of the same as well as the distribution of the money on the repair work, tires, parts; or, in the case of a credit memorandum, for what the credit has been extended and how much of it goes to tires, equipment, etc.

13. **Material Received Record**—All material which is received by the company and which has been sold before is recorded on a special form, kept in a binder. This form is shown in Fig. 5, being 11 by 12 inches. It is printed on both sides. The date when it was received, the party by whom it was sent, the number of the credit memorandum, etc., as well as particulars referring to the part itself are entered in detail. The form is large enough to afford space for forty entries on one side.

14. **Claim Sheet**—All parts which have been returned to the Colt-Stratton Co. are sent by it to the Cole factory in Indianapolis with a claim sheet, Fig. 17. It is 8.5 by 11 inches, printed on yellow paper, and is filled out with a complete list of the material sent to the factory. The number of the article, the

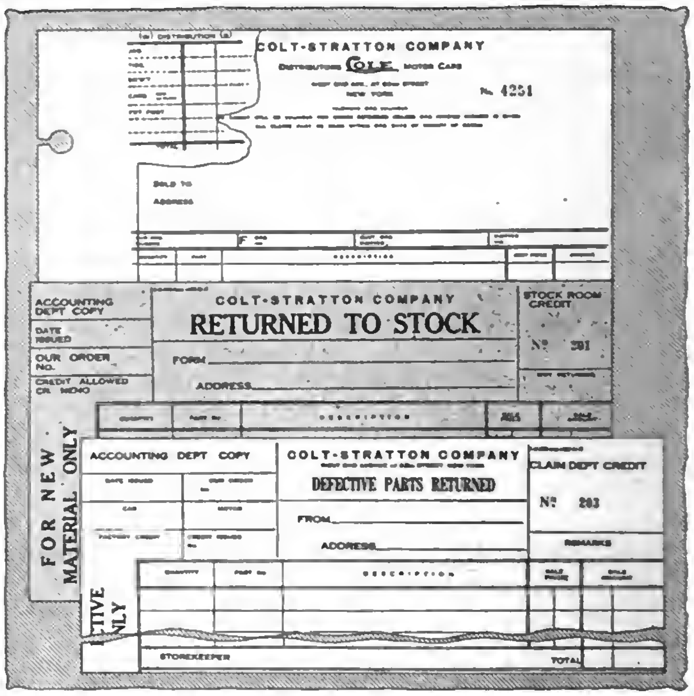

Fig. 12—Bill form used by Cole dealers. Fig. 13—Record for parts sold and then returned. Fig. 14—Record for defective parts returned to stock

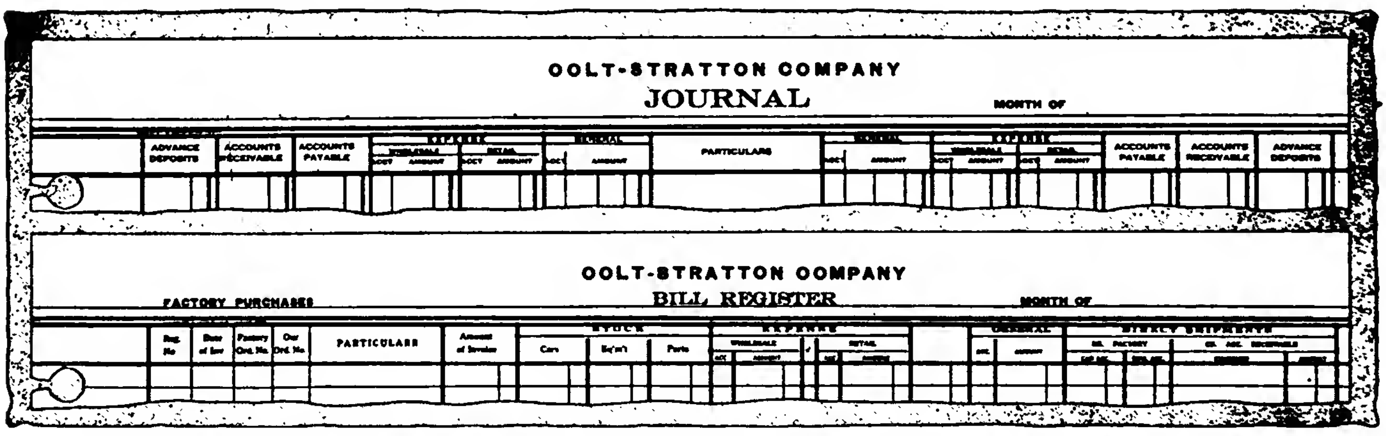

Fig. 10—Top of page from the Colt-Stratton Co.'s journal. Fig. 11—Design of bill register page used by the company

quantity, the car from which it was taken and the description of the article are stated on this sheet, which is signed by the manager of the claim department or technical department before the parts and the sheets are sent to Indianapolis.

15. **Shipping Order**—All materials leaving the service department are accompanied by shipping orders, Fig. 16, which are made out in quadruplicate. The original (white) goes to the accounting department, the duplicate (pink) is packed with the goods, the triplicate is filed in the main office of the service department and the quadruplicate remains with the stockroom, where the order is made out. The form is 11 by 8.9 inches, and every single detail referring to the transaction which results in the shipment is recorded on the order.

16. **Bookkeeping Forms**—Bookkeeping operations are carried out on four forms, which are held in four distinct binders. Fig. 18 shows the form used for recording the influx of money; the blank is designed more or less along lines of ordinary ledger leaves except what specific provisions are necessitated by the singular conditions of the automobile business. Each line has space for taking the name of the payer, date of payment, the amount of cash received, money deposited and where, discounts granted to the company, deposits made on transactions, cash come in on retail sales and the total amount for that cash receipt. Fig. 19 shows the cash disbursement sheet, designed similarly to

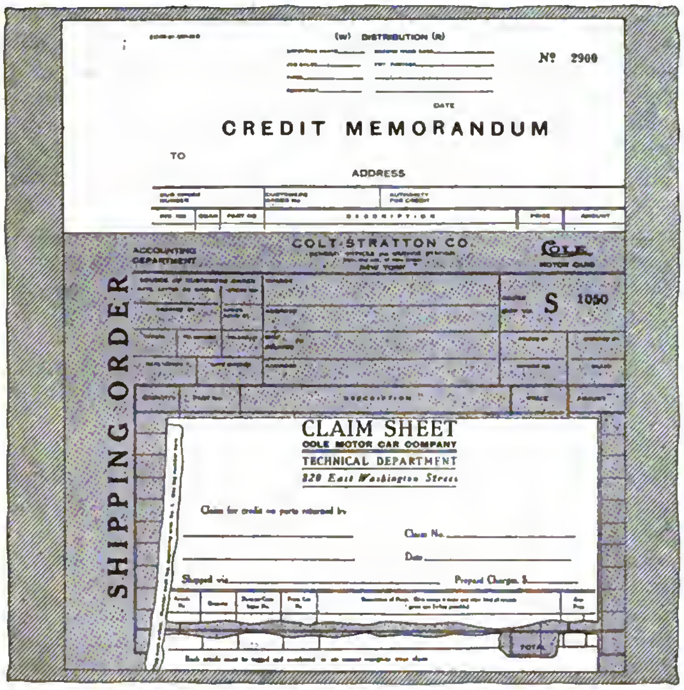

Fig. 15—Credit memorandum for returned and defective parts. Fig. 16—Shipping order used for recording outgoing materials. Fig. 17—Claim sheet

Fig. 19, but adapted to the opposite purpose. It affords space for the date, the name of a payee, the number of the check issued him if the payment was made by check, the amount of cash paid to him if any, the name of the bank on which the check was drawn, discounts paid, retail and wholesale expenses, petty expenses and total of the payment.

Fig. 10 illustrates the company's journal, the sheet being designed quite conventionally. Fig. 11 shows the bill register, on which every bill sent out and the details appertaining to the goods for which it is sent are recorded.

City Electrics Have Advantages

Few people who are desirous of owning an automobile are aware of certain advantages of the electric car for city and near-city service. Silence, cleanliness, and ease of control are features which are seldom reckoned with as worth money; but there is a distinct feature of economy about an electric. The following figures bear this out.

In New York City an electric is garaged, charged, cleaned and generally cared for by any of a number of garages for $40 a month; not forgetting delivery at the owner's house and calling for the car, both once a day. In other words, for $40 a month, or $480 a year, all expenses except car depreciation and tire cost are taken care of. Figuring a set of four tires, guaranteed to last for 10,000 miles, at $280, the cost of operating an electric automobile per year is as follows:

Depreciation (25 per cent. of $2,300)	$575
Garage, current, etc.	480
Tires (27.39 miles on each of 365 days)	280
Repairs, accessories, etc. (high estimate)	100
Total	$1,435
Operating cost per day	$3.94
Operating cost per mile	.143
Operating cost per day per caput (4 persons)	1.31

For less than $4 a day the car can be made to travel over more than 27 miles every day in the year. This means that it will take the owner to business; having been sent back by a clerk or the like; it will serve to take miladi to her places of shopping, and it will furnish a means for both and perhaps a child to get a sniff of fresh air after the hours of business. The cost to each of the three members of the family will be $1.31 a day. But the car will do more than that. If the owner is a doctor or lawyer, it may be necessary to use the electric more than 27 miles a day at a slightly higher cost, on account of the additional current needed; but the ownership and use of a car will result in direct gain of business, as everybody rather deals with a successful physician or attorney—that is, one who can afford such modern equipment as an automobile—than with one who cannot.

There are districts, such as Westchester County in New York State, where a car owner can draw any amount of current for his car at the cost of $10 a month, and such a condition, of course, makes the ownership of an electric still easier and more pleasant. As the radius of action is from 50 to 80 miles on a charge, a nice trip may be taken any day without having to stop during the day for recharging.

The Rostrum

In which Letters from Readers Are Answered and Discussed

Owner Uncertain as to Use of Cut-Out

Wants to Know if He will Increase Power by Using One—Another Seeks Road Information—Spring Wheels Advocated—Using Carbon Remover—Cleaning Carbureter with Air Blast—Locating and Remedying Plug Trouble

Effect of the Cut-Out on Power

EDITOR THE AUTOMOBILE:—I am preparing to go on a long tour this summer and would like to know whether I would develop more power if I use a muffler cut-out.

East Orange, N. J. F. E. S.

—Several tests were made on a car at the laboratory of a prominent factory in Detroit, Mich., in order to determine the actual loss of power developed by the attachment of the muffler. The tests showed that the difference in power developed with the muffler on and with the cut-out open was very small. Tests were made by the Packard Motor Car Co. at its Detroit, Mich., laboratory with a 30-horsepower motor without a cut-out, the muffler being merely removed from the line. In this way a higher horsepower is developed than without a cut-out, as shown in the curves, Fig. 1. The results of the test are given in the following table:

Revolution per min.	Horsepower with muffler attached	Horsepower without muffler	Horsepower difference Less	Horsepower difference Greater	Corresponding speed miles per hr.
500	23.7	21.5	—2.2	...	17
600	27.8	26.2	—1.6	...	20
700	31.7	31.2	—0.5	...	23
800	33.8	36.0	.....	.2	27
900	38.9	40.0	.....	1.1	30
1,000	41.6	43.0	.....	1.4	33
1,100	44.2	45.6	.....	1.3	37
1,200	46.6	48.2	.....	1.6	40
1,300	48.1	51.0	.....	2.9	43
1,400	49.2	53.4	.....	4.2	47
1,500	50.7	54.7	.....	4.0	50
Total Ave.		41.0		1.13	

From this table it can be seen that the average difference in power gained by removing the muffler varies between 2.75 and 1.125 horsepower. The removal of the muffler gives the same results as a cut-out having an efficiency of 100 per cent. The differences in power caused by using the cut-out will be less than those shown in the tabulation.

Road Conditions in the Oranges

Editor THE AUTOMOBILE:—I expect to tour New Jersey in the near future and would like to know of the road conditions, especially through the Oranges. I expect to go to Greenwood Lake, and have heard that the roads were not in very good condition last fall to that place. Have they been repaired as yet?

New York City. S. E. F.

—The roads are now in fairly good condition, though a few of the less important are now being repaired. The Newark turnpike is not in as good shape as reported, and we would advise slow going over it. The roads through the Oranges are especially excellent, as are those up to Greenwood Lake.

Says Spring Wheels Cure Bumps

Editor THE AUTOMOBILE:—The pneumatic tire, inflated and on a smooth road, is almost ideal in its action. It absorbs the pebble or throws it to the side. But a tack, jagged glass, or a sharp-pointed stone projecting from the surface of a rut interrupts its usefulness. The dust caused by its passage is an imposition on the residents along the way amounting almost to an injury. On a rough road the rebound is so rapid that the rider is bounced from the seat even to the destruction of his hat against the top. The thoughtful driver is never care-free. Hard work, expense and danger follow in his wake. Ordinary precaution requires that he carry spare parts and that he remedy all faults as soon as discovered. Many times he leaves his car at the roadside to await repair-parts far away.

The automobile is a pleasure-giver beyond compare. If life is worth living it is worth keeping. Question: How can the tire be made safer, more dependable?

The solution may be approached by studying the bump in extreme cases. Bumps, for the most part, are caused by the violent dropping or lifting of the car. Usually the drop and the lift follow each other in one sequence or the other.

The moment before the drop the tire and body spring are both compressed by the load. At the instant of the drop the load is released from both. The tire comes to normal form. The springs, coming normal, throw the axle and wheel swiftly down. When the impact comes the loosened springs and clips rattle, the load meantime falls and its momentum is finally stopped by the joint compression of the tire and springs. This compression is greater than the amount required to carry the load and hence the rebound.

The moment before the lift the tire and springs in normal compression meet a perpendicular obstruction. This presents a small surface to the tire which, therefore, is greatly compressed at one spot so that sometimes the two inner surfaces come together. For an instant the tire is solid noticeably. The springs are again compressed beyond the normal and a rebound follows; at the proper time a rattle.

In both cases the load reciprocates in gradually diminishing traverses until its energy is absorbed. If the time between the drop and the lift or the lift and the drop is sufficient to allow the tires and springs to return to normal compression the bumps are of bearable class. But if the sequence either way is quick enough so that the spring and tire cycles overlap, the bump is violent. This explains the deadliness of the high crossing and the small hole in a pavement. If this last is of correct width and so deep that the tire does not touch the bottom, the bump resulting is the king of bumps.

The cycle of the passenger is always a little behind that of the car. The seat is started up before he stops going down—bump—and the lag of the wheels and the axle caused by the relaxation of the springs does not affect his course. He leaves the seat and on the return falls against the seat, then rapidly rising—bump.

Now what can be done for him?

It is necessary to have something under him to check his course to the blow. So cushion-springs, body-springs and pneumatic tires are provided for this purpose. The greater the distance through which he is checked before he is stopped the less the blow. Anything which curtails the compression of the springs is a positive detriment to him. If the springs and tires could slowly return to normal compression to be ready for the next call for their services the bump would be almost eliminated.

In the case of the springs this can readily be done by a cylinder and plunger working in oil, the plunger valve allowing free compression of the spring but limiting the return to the speed of a leak. This would stop the relaxation of the spring in the drop, the rattle probably at all times, and the lag of the wheels and axles in the rebound. Such a device would hardly be necessary for the cushion-spring, though applicable.

But perfect government of the action of a pneumatic tire has not yet been devised. It seems impossible. The pneumatic tire is too resilient despite regulation of the springs as outlined above. The area of the contact multiplied by the internal pressure is always equal to the load and as the load is augmented by the drop or the lift the rebound must always come. Various designs are existent, placing the tube within the wheel, in which the action of the rim about the hub could be regulated. But heat and abrasion, the destroyers, make this but a sorry makeshift.

Puncture Not a Tire Destroyer

We hear much of punctures. The puncture, although it may deflate a new tube, need scarcely be considered as a tire destroyer. Neither should outside abrasion. Real punctures are exceedingly rare. Abrasion of cotton is the tire destroyer. Do you remember the see-saw of string you made in your youth and how quickly the string cut through? That is the action going on in the shoe whenever the car moves and it cannot be stopped or remedied. Anyone who buys a puncture-proof tire or tube or cover, or who has an old shoe retreaded is a gull.

But, after all, the greatest discontent comes from the interruption. Is there an automobilist who would not welcome a wheel of fair carrying performance, provided he knew it would so carry with all the certainty of his father's carriage wheels? How if it were impossible for a pneumatic-tired wheel to equal its carrying-performance?

In November, 1910, a set of spring wheels, with solid tires, were installed on a certain car. The front wheels have been on the car continually since and have never caused one moment's delay. On two occasions in 1912 one spring was broken in the right wheel and replaced the next day, the car running as required meantime. The original rear wheels were taken off in August, 1912, to make way for an improved set. They had never caused one moment's delay. One spring broke in the right wheel of this pair in August, 1911, on a Friday and was replaced the following Tuesday after running 350 miles. The broken spring made no difference in the riding and did not rattle, though still in the wheel. The rear wheels last installed have had no repair of any kind. They have traveled 5,000 miles, the old rear wheels 7,000 miles, the front wheels 12,000 miles. The front tires, side wire type, are worn .75 inch in diameter, but the corners are mostly there. They will probably give out in the base, as such tires do, but look good for many miles. The present rear tires, wireless, show little wear. If they wear down to the hard rubber, as the manufacturers say they may, 30,000 miles is easily within their life.

The car equipped with spring wheels weighs 800 pounds more than with pneumatic-tired wheels, but without change of engine or carbureter ran 30 per cent. farther per gallon of gasoline in 1911 than with pneumatics in 1910. The dust raised is very much less; steering very much easier.

The wheels are not as resilient as pneumatics. On smooth pavement no difference in riding can be noticed. On rough roads they excel pneumatic-tired wheels; no passenger has ever admitted to leaving the seat. This car, as all single-tired solid-tired cars do, skids very easily. Chains can be used as on pneumatics and, very strangely, the passenger is hardly aware of their presence.

The study of spring wheels was started in 1904; the course is not yet completed. It is easily possible to make springs of long life to carry any load. A truck-wheel combination can be built without rubber which will on any road absorb the full quantity of power delivered to it from the engine.

Buffalo, N. Y. HARRIS T. DUNBAR.

Wants to Tour in New Jersey

Editor THE AUTOMOBILE:—I intend to run down to New York City this summer and would like to tour in New Jersey for a few days.

2—Will it be necessary to have a New Jersey license or permit? CARL E. FOSTER.

Syracuse, N. Y.

—1—It will not be necessary to get a New Jersey license providing you do not stay in the state more than 10 days.

—2—In mapping out a route from Syracuse to New York City and then touring New Jersey, we would suggest that you follow the routes given in the Blue Book (Nos. 321, 330, 497, picking up 455 at Owego, 409, 152-R and 51-R), passing through the following cities: Ithaca, Binghamton, Scranton, Delaware Water Gap, into New Jersey at Easton, thence through Hackettstown, Morristown, the Oranges, Newark, Weehawken and across the ferry into New York City. The roads are in excellent condition. There are many beautiful and interesting tours in New Jersey, the favorites being the run down the coast and that through Lakewood and the hills of the northern part of the state.

Using Liquid Carbon Remover

Editor THE AUTOMOBILE:—I want to use a liquid carbon remover. The directions tell me to put the liquid into the cylinder and leave it there for a couple of hours. As it takes a large quantity for each cylinder and as the stuff is very expensive, I would like to know if, in your opinion, it would harm to use the same liquid for more than one cylinder after it has stayed in there for some time.

Brooklyn, N. Y. READER.

—It will do no harm to use it if you can. In many motors, the piston rings are not tight enough to hold the liquid for a

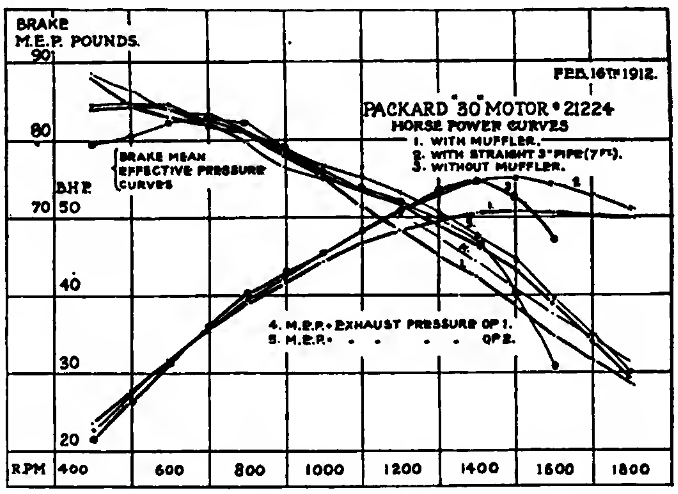

Fig. 1—Curves showing the effect of the use of a muffler cut-out on the power developed by the motor

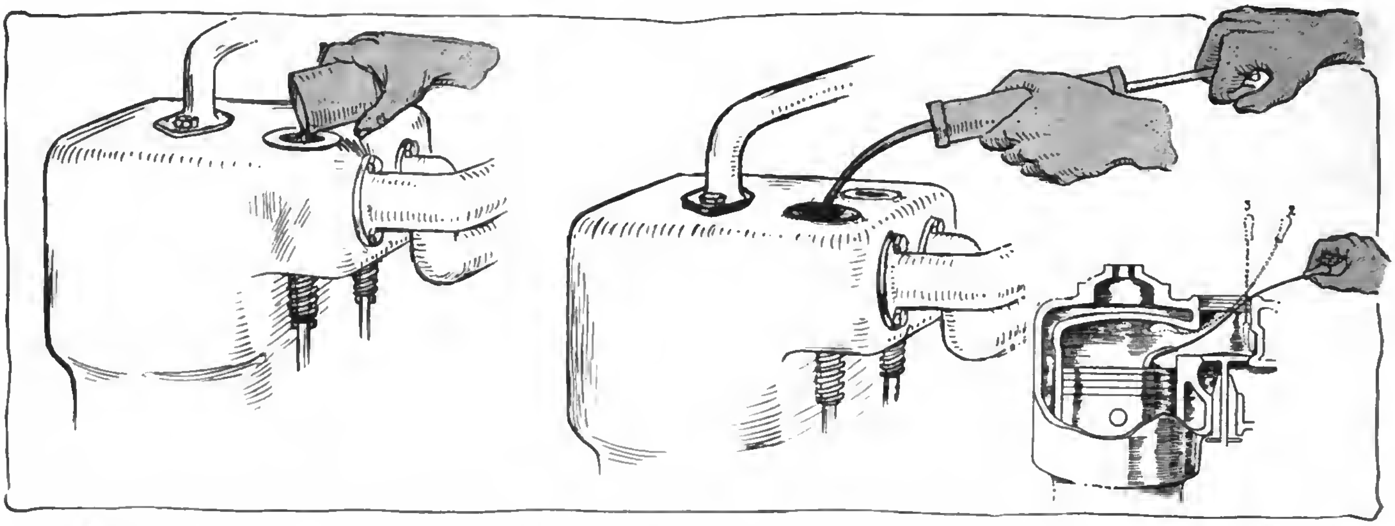

Fig. 2—Showing the steps in the application of a liquid carbon remover to the cylinders. Left, pouring in the remover; center, drawing it out by means of an oil gun; right, using the scraper

long enough time. The liquid can be drawn through any one of the openings in the top of the cylinder by means of an oil gun, as shown in Fig. 2. It is best to remove the valve cover cap and then the opportunity of using a scraper to take out any loose pieces is presented. In the illustration the method of working the scraper around is shown.

Carbureter Cleaned with Air Blast

Editor The Automobile:—My car has suddenly developed a bad case of asthma, or whatever the corresponding disease in an automobile may be. When in good health it will respond quickly to the throttle and will fairly jump forward when the accelerator pedal is pressed. Since it developed the strange malady, however, it has been behaving in a very singular manner. When the accelerator pedal is pressed it will sputter a few times and then the motor will die. If I quickly throw out the clutch and let the car coast, it will start the motor again by the momentum of the car. The motor will then run about a half minute and repeat the performance. What can be the matter with the car? What is the cure?

Williamsbridge, N. Y. R. T. Corry.

—Your gasoline line is dirty and does not allow the fuel to flow through the line as rapidly as it should. As soon as some of the gasoline at the top of the float chamber is consumed, the motor will stop until a sufficient quantity oozes through the line for it to run a short time again. The motor will then stop again and you will have to shut it off for a while. The quickest and best way to cure the trouble is to blow out the carbureter line and the carbureter itself with compressed air. Remove the auxiliary air valve cage or any other removable parts of the carbureter, as shown in Fig. 4, and put the air hose for tire inflation into the opening. Turn on a good strong current of air. Empty out the gasoline tank and then put the air hose against the gasoline feed line and blow back towards the carbureter from the tank end. If you desire to blow through from the other end, disconnect the pipe line from the tank so that any dirt in the line will not be blown into the tank. Take the needle valve out of the carbureter and blow through the jet opening also.

Finding and Curing Plug Trouble

Editor The Automobile:—How do you find out when ignition trouble is in the plugs and not some other part of the electric equipment? I run continually on a high-tension magneto and of late have had a little ignition trouble. It is a perpetual miss in one cylinder at low speed. If the trouble is in the magneto I wont touch it, but will send it to the factory. If it is in the plugs I will renew the plug, but do not intend to buy a new one until I find out if it is possible for a plug to operate at high speed and not at low.

Boston, Mass. Alice Ames.

—You could find out in 5 minutes if the plug was bad and you knew what cylinder was missing by simply changing the plugs around and seeing if the miss still occurred in the same cylinder. You can readily locate the cylinder which is missing by the method suggested in Fig. 3. By means of a screwdriver each plug is short-circuited in turn. When the cylinder that is missing is short-circuited there will be no difference in the running,

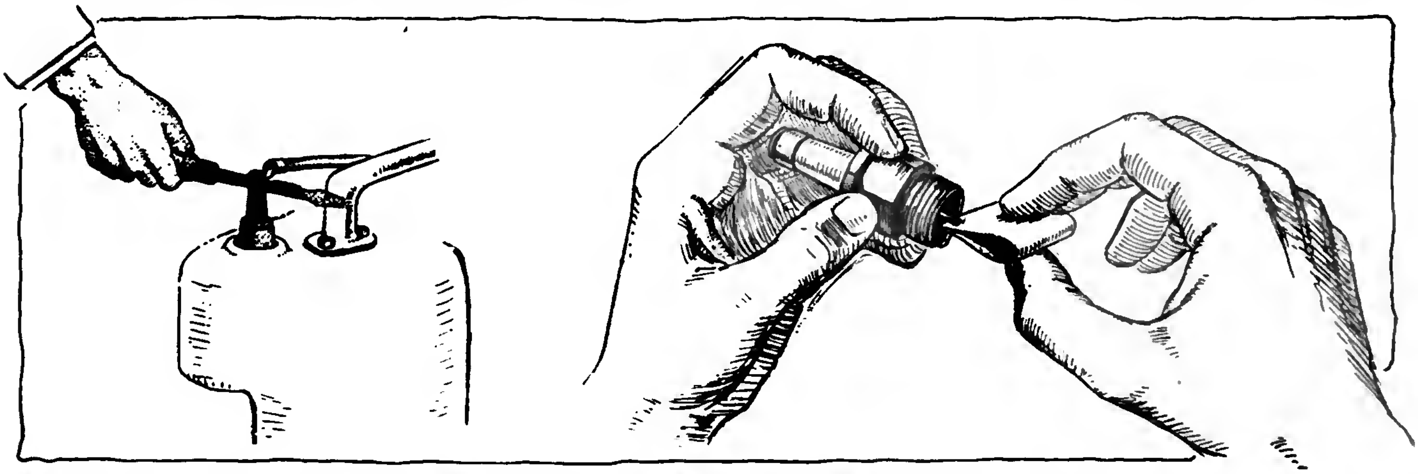

Fig. 3—At the left is shown an easy method of locating a cylinder which is missing fire, while at the right is a handy way of gauging the sparking gap on a plug suspected of missing fire

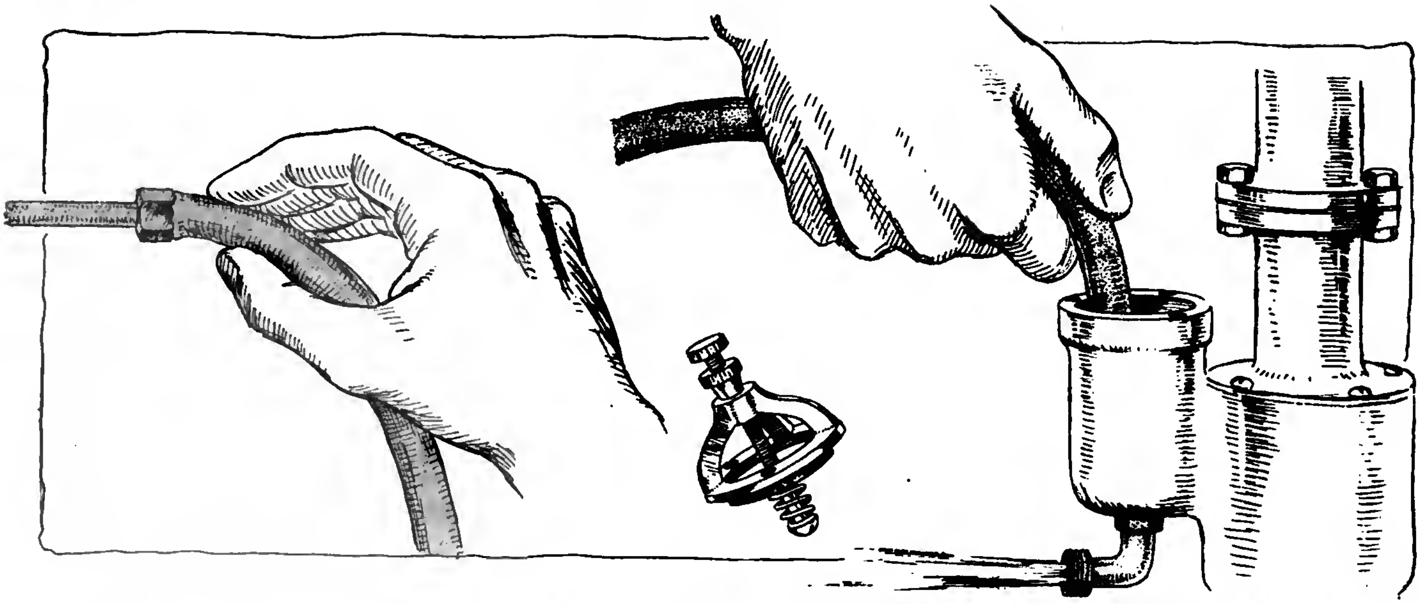

Fig. 4—Cleaning a carbureter with an air blast. Left, compressed air tube with a piece of copper tubing in the end for a nozzle; center, auxiliary air valve cage; right, blowing out the carbureter

while each of the other three will cause a noticeable falling off in power and speed. If changing the plugs around then shows that the miss always occurs in the cylinder that has the bad plug, examine the points and if they seem too far apart, they can be gauged by a card which has been folded over in the manner shown at the right, Fig. 3. The points should not be farther apart than 1-32 inch or closer than 1-64 inch.

Racing Game as a Business

Editor THE AUTOMOBILE:—Kindly inform me why the racing game cannot be put on a basis that would enable a driver (with ordinary means) to buy his car, or cars, and race them as a business proposition as well as the sport. It seems that the promoters of race meets, with the co-operation of drivers and manufacturers, could get together and put the game on a very firm foundation. At any rate, I would like to see the proposition discussed through THE AUTOMOBILE.

Lexington, Ky. WILLIAM B. BROWN.

—There is one reason why the racing game will probably never attain the elevation of a profitable business except perhaps on certain special tracks near large centers. In order for the drivers to earn sufficient money to make them go into the races as a regular calling there would have to be races frequently during the year. Otherwise there would not be money enough in it to pay a large number of men engaged in this work. The tracks on which the races are held are so large that they are exceedingly costly and require an enormous capital. This is especially the case when erected near cities large enough to support them and it has been noted that unless there is a particularly brilliant entry list, public interest is small. In tracks like the Speedway at Indianapolis or many other local tracks scattered throughout the country there will always be motorcycle and automobile racing and it will pay fairly on the investment. This is true where these races are held near an amusement center, such as the Brighton Beach track at Coney Island, New York City. The big national events are few and far between and these attract the main interest.

Waterjacket Leak Can Be Plugged

Editor THE AUTOMOBILE:—Is it necessary to have a welding job done on a cylinder in which there is a small leak due to a blowhole in the casting? This would be more of an expense than I care to stand just now and yet I cannot allow the cooling water to leak, especially at this time of the year.

Englewood, N. J. SUBSCRIBER.

—It is possible to mend a very small leak by plugging it, but if the leak is large or has a crack of any length extending away from it, it would be better to have it welded. On a small blowhole it will probably be possible to make the repair by means of an ordinary iron gas plug. The steps in the operation of making this repair are simple and are clearly shown in Fig. 5. The hole is first drilled to the size of the nearest possible plug. A half-inch gas pipe thread will have an internal diameter of .622 inch and the thread is the regular 1-2-inch taper pipe thread. The plug is dipped in red lead and screwed firmly in place and then sawed off. This will give a neat-looking job and if done right it will be nearly impossible to tell where the repair was made. The plug can be brought down to the level of the surrounding metal by means of a heavy coarse file. If it is desired to make a still neater job than is obtained by sawing off the plug and filing it down, a touch of paint or a repainting of the cylinder block is possible.

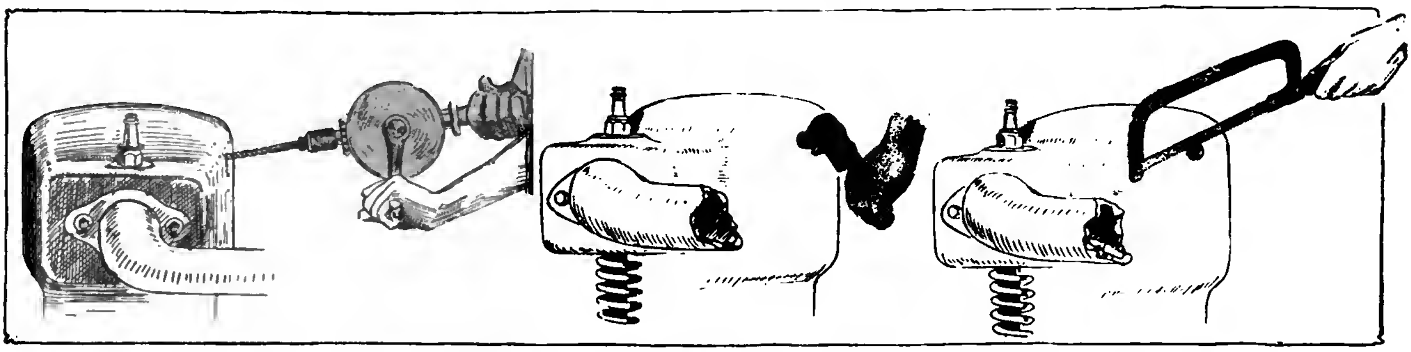

Fig. 5—Three of the steps in the plugging of a leak in the waterjacket. Left, drilling the leak to fit the plug; center, screwing in the plug; right, sawing off the head of the plug

Monarch Has Left Steer and Center Control

Long Stroke and Syphon Cooling Are Features—Car Built Light and Strong—Complete Equipment

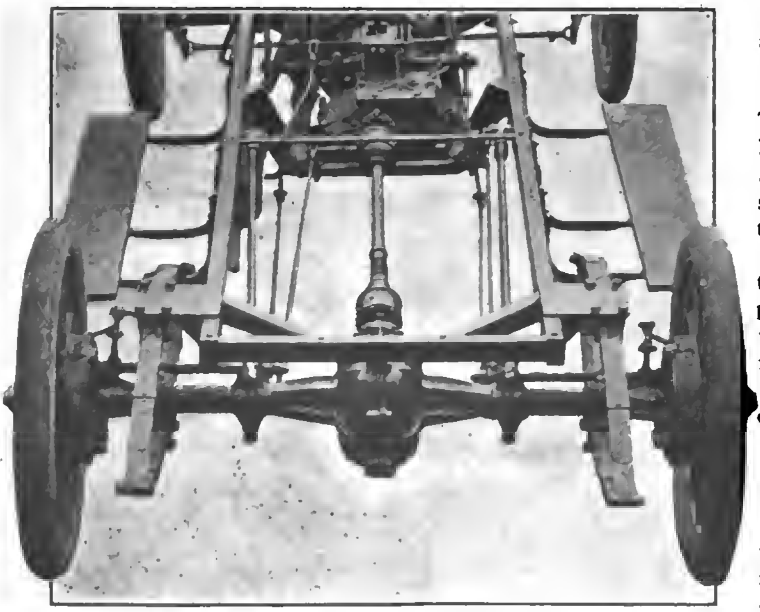
THE Monarch Motor Car Co., one of Detroit's youngest motor car building companies, the announcement of the formation of which was made in THE AUTOMOBILE recently, has made known the details of its product, which is now undergoing road test.

The car will present a very attractive appearance, having a streamline body of the torpedo type with the hood sloping down to the front as found on the Renault cars abroad and on several American makes. Probably the most unusual feature of the new design is the placing of the radiator under the hood, so that when the latter is raised, the cooling device is exposed. The filler cap of the radiator comes through the hood at the front, as shown, making it possible to fill it in the usual manner. Another feature is the placing of the gasoline tank under the cowl at the front of the dash, which is a growing tendency in this country as evidenced by the number of cars which have been designed in this way in the past year.

Considering the chassis in general, it is made up of three principal units, the motor, gearset and rear axle with the conventional methods of connection between these. A view of the rear system is shown herewith.

The motor is of special design for the car and is constructed along European lines in that it has a small bore and a long stroke, making for maximum power with low gasoline consumption. It has a stroke of 5 inches and a bore of 3 3-16 inches, giving a horsepower rating of 25. The cylinders are cast in pairs and are water-cooled, as already brought out. The cooling system is of the thermo-syphon type, eliminating the use of a circulating water pump.

The motor and gearset are mounted on tabular members which parallel the side frame rails and are hung from dropped cross-frame members at front and rear. This is clearly shown in the illustration. The motor has a forged crankshaft, which is carried on three main bearings fastened to the upper half of the crankcase. The connecting-rods are also forged and of light weight, as are also the pistons. The wristpin bearings are bronze bushed, while the wristpins themselves are light and hollow. The aim has been to obtain as light a set of reciprocating parts as possible, to aid in the elimination of vibration and to prevent injury to the motor when running at high speeds.



View of rear axle assembly of Monarch

Left side of five-passenger touring car

The timing gears at the front of the power plant are spirally cut and are accessible on removal of the gear cover in the conventional way.

The carbureter is placed on the right side of the motor and has a very short intake pipe with no pockets which is intended to prevent any condensation of gas. The carbureter feed pipe from the gasoline tank is also very short due to the close position of the tank to the carbureter. The chief advantage of this is that a flow of fuel is assured on grades and as long as there is any in the tank.

The lubrication is of the forced feed type, operated by a plunger pump worked through connection with the camshaft. The oil is pumped from the bottom of the crankcase up to the timing gears and to the main bearings, whence it feeds to troughs under the connecting-rods. These splash the lubricant up into the cylinders, lubricating the pistons. It then flows down into the reservoir at the bottom ready for recirculation.

Springs Under Clutch Leather

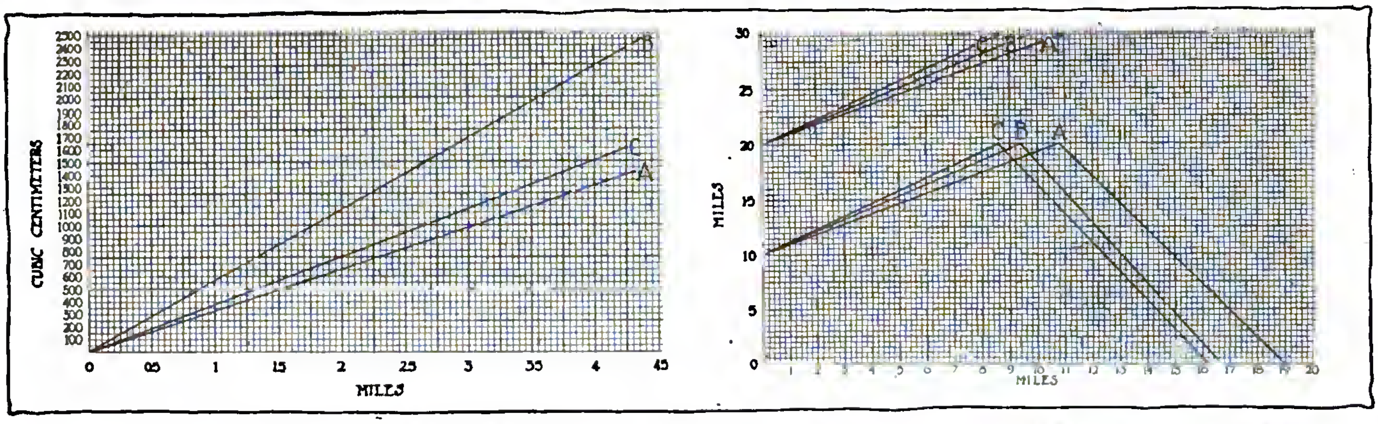
A leather-faced cone clutch is used, the cone having a 13-degree angle. Clutch-facing springs are placed under the clutch leather for easy engagement. The change gearset is of the selective sliding gear type, having three forward speeds and reverse. The power is carried to the rear axle through a substantial drive shaft, which is not enclosed. It is equipped with two universal joints, one at the forward end and one at the rear axle. The drive is carried by two side radius rods, which are attached to the axle and to brackets fastened to the side frame rails at their forward ends.

The rear axle is of the semi-floating variety with bevel drive. The ratio is 4 1-3 to 1. The brakes are mounted on the rear hubs and are external contracting and internal expanding, having a diameter of 12 inches and a width of 2 inches. The rear springs are elliptic, under-slung from the axle and swiveled on the bottom.

Other features are the left-hand drive and center control, electric cranking and lighting. As to equipment, this is most complete, consisting of demountable rims, electric horn, rain-vision windshield, extension top and side curtains, speedometer and full complement of tools.

The wheelbase is 110 inches, and while the price has not been definitely settled, it is thought that it will be $1,050.

EVERY BATTERY BOX has or should have a drain in the bottom. Where the battery is located on the runboard this drain is ineffectual. For that reason the box should be raised a bit above the running board even if the drain hole is carried through the running board. This will permit the electrolyte which may spill out from gathering under the bottom and destroying it. It also can be washed out whenever the car is cleaned.



Left, fuel consumption curve. A, kerosene; B, alcohol; C, gasoline. Right, acceleration curve. A, kerosene; B, alcohol; C, gasoline

Two Fuels from Kerosene and Alcohol

MILWAUKEE, WIS., June 9—A contender for the $100,000 prize offered by the International Association of Recognized Automobile Clubs for the best substitute for gasoline as a motor fuel has appeared in Milwaukee in the person of Prof. Frederick C. Raeth, who, with Kurtis R. Froedtert and William A. Biesmann, of Milwaukee, has perfected two different motor fuels, one using kerosene and the other denatured alcohol as a base.

Common kerosene and ordinary denatured alcohol, chemically treated by a secret process evolved by Professor Raeth, form fuels which in tests on air and water-cooled motor car engines and on small stationary or farm engines prove to be at least as good as gasoline and in some ways much better. Professor Raeth and his associates pursued their investigation in the direction of treating denatured alcohol to make it suitable as a fuel for internal combustion engines with the idea of appealing particularly to Europe, where the denatured alcohol industry has made great strides under the influence of governmental inducements. The cost of treatment adds but .5 to .75 cent per gallon to the price of the fuel.

Comparative tests of gasoline, the kerosene fuel and the denatured alcohol combination were made under the same conditions, and in point of fuel economy kerosene ranked first, gasoline second and alcohol third, as follows:

Fuel	Spec. Grav.	Distance, Miles	M.P.H.	Fuel Consumption, Pints
Alcohol	0.835	4.3	20	5.28
Gasoline	0.70	4 3	20	3.36
Kerosene	0.805	4.3	20	2.24

The test was made on an Auburn five-passenger touring car, carrying a four-cylinder Rutenber motor rated at 40 horsepower and equipped with a Rayfield carbureter, hot-air-jacketed. The course of 4.3 miles through Wauwatosa provided practically every highway condition.

An ordinary aspirator bottle, with a capacity of about 1,750 cubic centimeters, graduated up to 1,500 cubic centimeters was used as a container for the various fuels. A split-second stopwatch was used.

A striking characteristic of the denatured alcohol fuel was the ease of starting the motor. The temperature at the time of the tests ranged between 57 and 63 degrees Fahrenheit. The car was drained of gasoline and allowed to cool for about 10 minutes. The alcohol fuel was then introduced and the motor started as readily as with gasoline. It was immediately noticeable, however, that the motor was being starved, and the fuel adjustments of the carbureter were opened several turns, the air adjustment remaining untouched. The car was then run at a speed of 20 miles per hour over a distance of 4.3 miles, which required 5.28 pints of fuel. More difficulty was experienced in keeping the car at 20 miles per hour than with gasoline.

Then the motor was operated on gasoline. The kerosene was introduced as the alcohol had been previously, and the motor turned over. The motor started readily, but lagged after a few revolutions, when the gasoline vapor in the cylinders was exhausted. It was necessary to do considerable adjusting on both air and fuel valves of the carbureter in order to make the kerosene mixture run the motor smoothly. After the motor became hot, the sluggish action disappeared and the car was run 4.3 miles on 2.24 pints. The motor did not at first show the life and dash that was displayed on the alcohol fuel and on gasoline. It climbed hills with much less labor than on either alcohol or gasoline. The kerosene used in the test was of the lowest grade.

Each time the motor was stopped it was necessary to use gasoline before throwing in the kerosene fuel.

Gasoline came out ahead in the acceleration tests. It required 8.5 seconds to accelerate the car from 10 to 20 miles per hour and 8.75 seconds to accelerate from 20 to 30 miles per hour on gasoline. Alcohol ranked second, the 10 to 20-mile acceleration being accomplished in 9.5 seconds, and 20 to 30 miles, 10.5 seconds. On kerosene, it required 11 seconds from 10 to 20 miles and 11.5 seconds from 20 to 30 miles. The specific gravity of the kerosene used in the formal test was .805, or 43 degrees Beaumé. The boiling point of this mixture was 112 degrees Centigrade.

The alcohol fuel tested for specific gravity at .835, or 38 degrees Beaumé, and had a boiling point of 67 degrees Centigrade. Neither of two Raeth fuels has an offensive odor. At no time was smoke detected at the exhaust while the car was running.

Filling the aspirator bottle with fuel for the test

Henry Souther, chairman of the General Standards Committee, who presented the report of the Iron and Steel Division

Combine Hardness and Elastic Limit

Iron and Steel Committee of Society of Automobile Engineers Furnish First Test Figures

Progress Made in Standardizing Demountable Rims—Nomenclature Division Shows Activity—Other Committee Report

THE healthy condition of all divisions of the Standards Committee of the S. A. E., the work of which is the most important feature of the society, was evidenced from the comprehensive reports of the older divisions and the progress reports of the more recently-formed divisions of the committee.

There were in all ten divisions scheduled to present reports at the session. Seven formal reports were heard and variously disposed of, while three of the divisions, though unable to provide anything definite at this time, stated through their chairmen that they were progressing and would undoubtedly be able to report at the winter meeting. Three were referred back to their divisions for further consideration, these being the fifth report of the Broaches Division, the fourth report of the Ball and Roller Bearings Division and that part of the report of the Electrical Equipment Division which referred to wiring systems.

The following shows the society's disposition of the Standards Committee's work:

Division	Chairman	Disposition
Iron and steel	Henry Souther	Accepted with amendment.
Ball and roller bearings	David Fergusson	Referred back.
Truck standards	Wm. P. Kennedy	No report.
Commercial car wheels	Wm. P. Kennedy	Accepted.
Electrical equipment	A. L. Riker	Wiring systems sub-committee referred back. Insulation sub-committee showed progress. Standard instructions for battery makers sub-committee accepted.
Broaches	C. W. Spicer	
Passenger car wheels	Henry Souther	Referred back.
Nomenclature	E. J. Stoddard	No report. Progress.
Miscellaneous	Arthur Holmes	Accepted. Progress.
Motor testing	J. O. Heinze	Accepted.

The fourth report of the Iron and Steel Division of the Standards Committee was presented by Henry Souther, chairman.

Iron and Steel Division Reports

The materials specified in detail hereinbefore include the most important ones available to the builder of automobiles. It is obvious that there are more kinds of material specified than are likely to be used by any one manufacturer.

The results of physical tests, whether tension tests or otherwise, are largely dependent upon the mass and form of the specimen tested. this is particularly true of heat treated steels. For the foregoing reason, all results of physical tests are comparative, and in order to make the comparison a proper one a uniform test specimen must be used.

The committee therefore decided that recommended practice should be the use of the S. A. E. standard test specimen, this specimen to be treated always in its finished form and not in the rough shape from which the finished specimen might be cut.

The figures for physical characteristics refer to those obtained on specimens prepared from sections common in automobile use, that is, bars from 1 inch round up to 1.5 inches round. The high yield points may be obtained with severe heat treatments, and the lower yields points with treatments less severe.

The yield point is specified rather than the elastic limit. The yield point is measured by the drop of the testing machine beam and may safely be relied upon for material having a yield point not in excess of 100,000 pounds per square inch. With material having a yield point in excess of 100,000 pounds per square inch the true elastic limit should be obtained by means of an extensometer.

In addition to the usual physical characteristics the "hardness" tests have been considered, as obtained by means of the Brinell ball test and the Shore scleroscope. The Brinell test recommended by the committee is the use of the 10 millimeter ball and 3000 kilogram load. It is pointed out, however, that the Brinell test must not be used on soft steels less than .5 inch thick, or an areas small enough to permit the depression to flow toward the edges of the specimen. With hard steels, where the depth of the depression and the flow of metal are less material as thin as .25 inch may be so tested. The Brinell test may be fairly made on surfaces that are free from scale and smooth.

The Shore test (scleroscope) must be used only on surfaces that have been carefully polished and free from all tool marks, file marks or grinding scratches.

The report further gives the specifications for carbon steels, screw stock, steel castings, nickel steels, nickel chrome steels, nickel-chromium-vanadium steels and silico-manganese steel.

For valves, and especially exhaust valves, high-speed tool steel is now being used. The exact analysis of this grade of tool steel is not important, as there are many kinds available, all more or less alike in composition. The chief characteristics of such steels are the tungsten (18-20 per cent.) and chromium (4-10 per cent.) contents. This quality of steel has proven very successful in the case of motorcycle valves, where the heat is intense.

The use of specifications for cast-iron in the present state of the foundry art is not very easy. The foundryman, if he is not accustomed to work to analysis, will object, although his iron may be within the specifications given 90 per cent. of the time. Moreover, if there are any defective cylinders he will be likely to lay it to the composition of the iron, whereas the fault may lie in his foundry methods, apart from composition.

Consequently these specifications should be used as indicating the ideal mixture—something for the foundryman to work to, even though he may not be willing to guaranee the analysis.

If trouble is experienced with cylinders, analysis of samples of the iron will show whether or not the composition is somewhere near what it should be. If the composition is very far from the specification here given, the purchaser will be justified in putting up strenuous objection.

Iron in accordance with this specification will be strong and reasonably close-grained in the thicknesses cast, and one that wears well.

The remarks made in connection with the gray iron specification apply even more strongly to malleable iron. Iron of the composition given, properly annealed, will make a strong and tough casting; but improperly annealed it will not make a good casting.

Castings that are received brittle may be so from two causes: First, unsuitable mixture of iron; second, incomplete annealing. Consequently, if brittle castings are received, they should be analyzed, and if the analysis is correct, then it is certain that the annealing operation was not properly performed.

The following table is a sample of those included in the Iron and Steel Division's report linking the hardness with the other properties of the various steels.

Considering the report, the chairman stated that as soon as the physical and chemical specifications for any metal were coupled together in making requisition for any grade of material, trouble for the steel works was likely to result. It was therefore requested that either the chemical or the physical system be adhered to in ordering, and not a combination of both.

The report contains the first data yet published by the division connecting the elastic limits and the hardness of steels. This is but the start of investigation to link these properties.

The specifications for valve materials have been omitted from the present report. In their place reference has been made to what would seem to be the ultimate metal for valves. It is a grade of high-speed tungsten tool steel, which has as much as 18 per cent. tungsten content.

In some cases the yield point of the material has been substituted for the elastic limit, this being regarded as the logical property to specify, as to the trained man the yield point clearly indicates the elastic limit. No attempt has been made to define the elastic limit in these specifications. Of course, for the harder steels there is no yield point and the extensometer is then called into play. In a word, the division is splitting no hairs as to the specification and leaves it up to the trained observer to tell whether the specimen is up to the elastic limits required for his work.

George F. Fuller, Wyman & Gordon Co., objected to the insertion of data in the report which were not borne out by a great many tests. The physical properties of steel he characterized as being the most important feature. Any definition of them should, therefore, be approached with the greatest circumspection. They may be only recommended practice, he said, but in the trade they have become to be regarded as actual specifications which must be lived up to by the steel companies. Mr. Fuller called attention to a number of discrepancies in the tables of physical characteristics of the various steels.

Chairman Souther pointed out that the list of physical characteristics as printed has no relation whatever to the specifications, instructions or notes contained in the body of the report. They are mostly freaks, he said, which have been published to show what results have been obtained in different instances. It was his contention that it is only by the publishing of such figures as these that any results are obtained and any accurate gauges secured.

In these tables an attempt has been made for the first time to incorporate data on the Brinnell hardness tests and on those obtained with the Shore scleroscope. The data of this kind are slowly accumulating and becoming more valuable. They have the advantage that they can be applied to every individual piece without mutilating or destroying the piece in any way, whereas most physical tests ruin the test piece for further use. This information is being gathered at the request of the society, and while there are many discrepancies, the data have been secured from widely divergent sources and under many conditions which accounts for them.

Mr. Fuller advocated that from fifty to 100 tests be made of each kind of steel before the data on that kind be published, stating that they are bound to be used by some.

To close the discussion, Chairman Souther proposed a paragraph be placed over the tables of physical characteristics to the effect that the lists are only possibilities, not for use in connection with the purchase of steels and must not be used as such. He showed that it would be next to impossible to wait for 100 tests of each metal as this would never get the data anywhere. A beginning has been made at least.

With this paragraph inserted over the physical characteristic tables the report was accepted by the society.

Light Wiring Report

The report of the sub-committee on one and two-wire systems for electric lighting was presented by David Fergusson, who stated that they could not recommend the one-wire system, while they favored it, and that the committee had not yet reached a conclusion. The work was referred back to them.

Frank Conrad, Westinghouse Electric & Mfg. Co., read the report of the subdivision committee on insulation. This was a progress report because it had not been referred back through the parent Standards Committee for its approval. It was the belief of the members of the sub-committee, however, that a 600-volt test for insulation on the car wiring was correct, although many thought it was too high for automobile work. He stated that the American Institute of Electrical Engineers would probably co-operate in this standard.

E. T. Birdsall stated that he thought the test should be 1,000 volts alternating current because the insulation might stand the 600-volt test when new and then in the course of a few months might fall off to such a degree in quality that it would not. If the 1,000-volt test were given it would be sure to guarantee the fact that the insulation would withstand the 600 volts a few months later.

William H. Palmer, Jr., Electric Storage Battery Co., read the report of the sub-committee on standard instructions for battery makers. This committee had submitted the instructions to five prominent storage battery makers who had agreed to them. The instructions follow:

1. Put the battery where it can be seen.
2. Make a rigid installation.
3. Put water in it from time to time and then leave it alone.

The report was accepted and unanimously adopted.

W. H. Conant, Gould Storage Battery Co., asked if there was any tendency to standardize the sizes of batteries. He thought

S. A. E. party embarking on City of Detroit III on Wednesday for sessional excursion to the Soo and Mackinac Island that there ought to be some work done by the committee in at least standardizing battery sizes for batteries of given capacity rating. This was put in the form of a motion and the work turned over to a committee.

Miscellaneous Division Report Accepted

A short report of the Miscellaneous Division was submitted and accepted. Further standardization of yoke and rod ends, magneto couplings, etc., was reported.

A sub-committee on carburetion is working to advantage, but was not ready to report.

The second report of the Nomenclature Division was one rather of progress, and in order to show the line along which the division has been working, some correspondence carried on with the I. A. E. was read. That body is co-operating with the S. A. E. in this work, as is also the patent office. Charles Wheeler, I. A. E., of the sub-committee of the standards committee of the I. A. E., assured the society that it has gone on record as proposing to confer with the Nomenclature Division before publishing any accepted terms. The I. A. E. committee also has the co-operation of the various other similar committees of Europe and also of the state department of England.

It has been found that the technical nomenclature of England and that of this country are quite different and it is proposed to eliminate differences wherever possible.

It was also stated that the rubber industry is reducing its nomenclature by some forty or fifty terms relating to the various grades of rubber, which is of interest in this connection.

Long Nomenclature Division Report

Excerpts from the rather lengthy report of the Nomenclature Division by E. J. Stoddard, chairman of the division, follow:

Without some standard, or criterion, confusion and chaos are inevitable.

The general language has an abundant literature which, within its recognised scope, establishes a usage with a particularity and absoluteness that is effective and almost proverbial. Ben Jonson is quoted as saying:

"A man coins not a new word, without some peril, and less fruit; for if it happens to be received, the praise is but moderate; if refused, the scorn is assured." "Supplee's Trench," 249.

In engineering it has seemed to me that the author has relied upon his publisher, and has shrunk before the literary frown as Napoleon before Talleyrand. I have not found engineering books consistent authorities on literary usage.

In automobile engineering we have at best a very scanty and incipient literature.

The nomenclature of the automobile is a part of the English language. Those conversant with the art are the most competent to form a judgment as to it.

The world has a right to ask for a suitable medium of intercommunication.

The profits and prestige of the profession depend upon the public estimate thereof. One might as well try to increase his income at doing piecework for an indifferent and absentee employer, as to increase his prestige and income solely by perfecting himself in the work of his profession. We know that the demand will advance as fast, or faster, than the increase in strenuousness and facility. The result is, of course, inevitably suicidal. The modern Prometheus will also be bound to the rock by his admiring and loving friend.

The public must be led in the right direction. It is willing enough to go.

Some of the arts and professions have a most impressive vocabulary. In the past the coinage of imposing words has had its effect upon the ignorant and unlearned. At present it is more apt to excite prejudice. It is not in accord with the spirit of engineering.

The society should not be characterised by words that express the egotism of the unlearned and indolent, nor the egotistical and selfish pride of the scholar.

Not by the unsupported decree of the society; the prestige of the French Academy was not sufficient for this. There can be no purely "Fiat Nomenclature."

It must be by the resolution of the society expressing, generally, a correct judgment, and this resolution must be consistently backed up and enforced by the influence of the society and each of its members. We must not only be right, we must be effective. I think the automobile engineers have a peculiarly favorable public to appeal to. It is made up quite largely of men of wealth, liberality and intelligence.

It is our duty individually and collectively to see that the reputation of the society is sustained in recommending a correct usage, by our influence making this recommendation effective; and it is also, and equally, our duty as members of society to see that the proper usage which has been recommended is adopted.

A judgment in each instance must be formed in view of, and in accordance with, a large number of facts. These facts must be collected so that they may be used to verify our judgment.

There is a great mass of material, good, bad and indifferent, that must be collected, sorted, trimmed, and its deficiencies supplied. This involves much work, and ability; it should be done largely by private enterprise, and the workman should reap his reward both pecuniarily and in the esteem of the members of the profession. The society as a whole is not adapted to this detail work.

On the other hand, it is very well adapted to record a judgment and distinguish between conflicting usages; or even, by getting the members together and testing them to work on a common line, to bring about a consensus of opinion which shall determine a usage; and this consensus of opinion, through the instrumentality of the society, may be brought about with data and principles in view, which ought to be considered.

The society may fix and record a judgment already existing as a consensus of opinion of its members; first, as to a principle dictated by good taste; second, as to a principle dictated by policy; or, third, as to a particular usage.

I understand that it is the office of the committee to select the matter that should be acted upon by the society, collect the data bearing upon each point and present such points and related data to the society.

One naturally feels a resentment when he is addressed in words he cannot understand. There is hardly any explanation that is creditable to both parties.

Toward the engineering profession the public is generous but ignorant. Knowledge should not be obstructed. Over 465 names for ninety-three parts of an ordinary engine lathe do not seem to invite a public acquaintance with that device.

A man must know more than his own profession or he will not know that. The curse of the Tower of Babel should be mitigated, not increased.

The word "carbureter" has been spelled in half a dozen different ways by good authority, and even now we can find it spelled in two ways, although the Standard Dictionary marks one as falling into disuse.

Shall we say "Jack-in-the-Box," "Balance Gear," "Equalising Gear," "Compensating Gear," "Differential Gear," or simply "Differential?" (The U. S. Patent Office says we should say *gearing* and not *gear* in this connection.)

Shall we say "Drip Pan," "Under Pan," "Shield," "Under Protection," "Dust Guard," "Dust Pan," "Mud Pan," "Sod Pan," "Grease Pan," or "Guard?" ('Dust Guard" and "Under Pan" are used by the U. S. Patent Office.)

Shall we say "Fender," "Wheelguard," "Mud Guard," or "Wing," and if we use "Mud Guard" shall we not be in danger of confusion with "Mud Pan," and if we use "Fender" shall we not be in danger of confusion with two or three other devices that are properly so called.

Besides what shall we do with the approximately vertical parts between the frame and running-board or wheelguards?

SYNONYMS

To the rule that two words for the same thing cannot long exist, a seeming exception is recognised in words expressing a different point of view or shade of meaning. Thus it would seem that "Equalising Gear" well expresses the mechanism that equalises the power of the engine between the two driving-wheels; or "Differential" the mechanism that permits a differential motion of such wheels. So it is conceivable that one term might accurately and clearly indicate a part from an engineering point of view, and another better express the generous enthusiasm of the amateur.

DERIVATIONS

In general literature words have been derived from the ancient languages by the learned who had sufficient prestige to enforce them. To the learned such words expressed a meaning due to their derivation and their derivation has had an effect even in their popular use, which, however, more and more departs from the original usage until often it is quite lost and the derivation forgotten.

In this art words are formed from our own language and therefore carry with them the meaning due to their derivation. The word "caterpillar" does not suggest usually to us a "hairy cat" or an efficient forager, but a "caterpillar-gear" is always suggestive, and to my mind not very happily so.

It was a barbarous age that pictured Vulcan acting as cupbearer to the gods as a droll figure limping from couch to couch while the hall echoed with the laughter of the assembled gods; and it was an abnormal imagination, unable to appreciate the beauty of reality, that personified the sciences as a powerful dwarf that made small what was great and magnified what was small; simply an illustration of the truth that comparisons are relative.

I am fain to admit that I like the smell and grime of the shop, where it is necessary, and the I like the smell of the laboratory, even the sulphuretted hydrogen and nitric oxide, when necessary, but I believe in proper ventilating hoods. Even if there is romance to us in these incidentals, this is not a sufficient reason for imposing them on our indulgent friends. It is not necessary that our nomenclature should carry with it the atmosphere of the shop.

A name in engineering should express the function of the object. The intention in the drivation of words is always to make the term descriptive, even when metaphor is used. The clearer and more definite the description the better.

Report of Commercial Car Wheels Division

(Formerly Wheel Dimensions and Fastenings for Tires Division.)

S. A. E. STANDARD MOTOR TRUCK WHEEL—EDGES OF PERMANENT METAL FELLOE BAND

We recommend that the permanent metal felloe band be rounded on the two outside edges with radius not to exceed 1-16 inch, and that one inside edge of the band have an angle of about 45 degrees, extending about 1-16 inch from the edge.

We further recommend that the previous recommendations as to tolerance in width of permanent metal felloe band be modified to read as follows:

	Plus	Minus
Tolerance in width	1-64 inch	1-64 inch

And, in consequence of the last-mentioned recommendation, that the previous recommendation as to trueness of band when placed on surface plate be modified to read as follows:

Either side of the band when laid on a surface plate must not clear more than 1-64 inch at any point.

TOLERANCE IN CIRCUMFERENCE OF PERMANENT METAL FELLOE BAND

In June, 1911, the division voted that the tolerance in circumference should be:

	Plus	Minus
Before application to wheel	1-16 inch	0
After application to wheel	1-8 inch	0

In February, 1912, the division, in view of the then more extensive manufacture of a rigid-base tires, recommended that the circumferential tolerance should be:

	Plus	Minus
Before application to wheel	1-32 inch	1-32 inch
After application to wheel	1-16 inch	1-32 inch

Both of these recommendations were accepted by the society, the latter, of course, superseding the former after a long discussion, it was:

Voted that the last-mentioned above tolerance in circumference of permanent metal felloe band should be modified to read:

	Plus	Minus
Before application to wheel	0	1-16 inch
After application to wheel	1-16 inch	1-32 inch

MEASURING CIRCUMFERENCE OF BANDS

In measuring circumference of the band, if there is no allowance on the tapeline itself, a correction amounting to three times the thickness of the tapeline should be made.

Below is given a statement summarizing the recommendations made in all (including the above, the fourth) the reports of the Wheel Dimensions and Fastenings for Tires Division; in other words, a complete statement of the matter contained in the three reports already accepted by the society, and representing a complete data sheet on the subject, if the recommendations contained in the above given report are accepted by the society.

Wheel Dimensions for Solid Tires

Demountable and Non-Demountable Rims

Single Tires

Width of felloe and band..........⅝ inch less than sectional size of tire.

Thickness of steel band............¼ inch up to 4½ inch tire; ⅜ inch on 4½ inch and larger tires.

Dual Tires

Width of felloe and band....Twice the sectional size of tire.

Thickness of steel band......⅜ inch for all sizes of tire.

Single and Dual Tires

Sectional size of tire	2	2½	3	3½	4
Minimum felloe thickness	1¼	1¼	1½	1½	1⅝
Sectional size of tire	4½	5	5½	6	6½ and over
Minimum felloe thickness	1¾	2	2	2	2¼

velopment of the Wire Wheel

m the Paper Read Before the S.A.E. and I.A.E. by George W. Houk

... wire wheels, G. W. Houk explained ...iting to discuss the subject from an engineering standpoint but wished to give the history of this type of wheel as he has found it here and abroad. The paper follows:

The object of this paper is to give a brief history of the wire wheel as developed in England and its adaptation to the American automobile for American roads.

Being associated with the motor industry abroad from its inception, I came to America in 1909 to follow the same vocation. Being in a position to draw comparisons between the American and foreign built cars, my attention was first drawn to the enormous tire expense when American road conditions were much in favor of the tire as compared with English and French roads, by reason of the hard and flinty surfaces of the foreign roads compared with the soft springy conditions of the American roads. Rarely I found a tire worn out—in most cases it was a rupture, caused by a blow. thus weakening the fabric of the tire, resulting in a blow-out. Abroad a tire is usually worn down to the last layer of fabric before giving way.

I then began to carefully study the unsprung weights of American cars compared with foreign cars. I found the greatest difference lay in the wheel equipment. I returned to England to find that wire wheels were attracting attention through their merit over wood wheels as tire savers, coupled with their great strength to resist side slips and the ease with which you could change a deflated tire to an inflated one by carrying a spare wheel.

Having known the firm of Rudge-Whitworth, Ltd., of Coventry, for a number of years as a builder of wire wheels, I found it began in 1905 by making a set of fixed wire wheels for a 90-h. p. Napier racing car, these wheels embodying its well-known principle of dishing the wheels; that is, making the outer set of spokes very much coned, the innet set nearly straight and so arranging the tangent that the inner spokes took nearly all the drive. These wheels first proved their efficiency in the Gordon-Bennett trials in Ireland.

In 1906 Clifford Erpe at Ormonde Beach drove the last 60 miles of the 100-mile race with one rear tire and nine spokes missing at an average speed of 99 miles per hour, winning the race. Having found the construction efficient for resisting lateral strains, caused by skidding around corners under high speeds, early in 1906 the company began to manufacture and commercialize the detachable wire wheel. In the hands of the public much useful information was obtained by careful attention to the smallest details during a period of 3 years.

As the wheel business became a factor in the trade many arguments arose as to the superiority of wire over the wood, or artillery type, of wheel. A series of tests was carried out at the laboratories of the Rudge-Whitworth company. The method of testing was by steady pulls to find out the lateral as well as the vertical strain. These showed such overwhelming superiority of wire over wood wheels that makers of wood wheels denounced this method of testing, saying it did not represent anything like the actual conditions to which a wheel was subjected while on a car. So the impact test was suggested by J. H. Lester, a serious student of automobile technology. Until the first series of impact tests were completed it was expected that the intense lateral rigidity of the wire wheel would show worse results than the wood wheel with its elastic yield. This proved quite the contrary, wire wheels showing up much better

Wheel Diameter Over Steel Band

Single and Dual Tires

Nom. outer diam. of tires	30	32	34	36	38	40	42
Wheel diam. over steel band	24	26	28	30	32	34	36
Exact circumf. over steel band; neglecting tolerance	75 25/64	81 11/16	87 31/32	94¼	100 17/32	106 13/16	113 3/32

Allowable Deviation from Precision in Felloe Bands

	Plus	Minus
Tolerance in circumf. of band before application	0	1-16 inch
Tolerance in circumf. of band after application	1-16 inch	1-32 inch
Tolerance in width of band	1-64 inch	1-64 inch
Tolerance of thickness of band	0.006 inch	0.006 inch
Tolerance in radius of band after application	1-16 inch	1-16 inch

Circumferential deviation from precise figure must be uniform across entire width of band.

Radial deviations must not occur at diametrically opposite points, and there must be no flat spots or kinks in band on finished wheel. Either side of band when laid on a surface plate must not clear more than 1-64 inch at any point.

Bolt Equipment for Side Flanges

All bolts to be ½ inch diameter

Outside Diam. tire	bolt diam. hole circle	Number of bolts	Outside Diam. tire	bolt diam. hole circle	Number of bolts
26	18½	6, 9 or 18	42	34½	10, 15 or 30
28	20½	do.	44	36½	12, 18 or 36
30	22½	do.	46	38½	do.
32	24½	8, 12 or 24	48	40½	do.
34	26½	do.	50	42½	14, 21 or 42
36	28½	do.	52	44½	do.
38	30½	10, 15 or 30	54	46½	do.
40	32½	do.			

Edges of Felloe Band

Band to be rounded on the two outside edges with radius not to exceed 1-16 inch, and one inside edge to have an angle of about 45 degrees, extending about 1-16 inch from the edge.

Measuring Circumference of Band

In measuring circumference of band, if there is not an allowance on the tapeline itself, a correction amounting to three times the thickness of the tapeline should be made.. Note—*All of the foregoing summary, so far as pertinent, applies to metal wheels.*

Bearings Data Not Yet Complete

On the recommendation of its chairman, David Fergusson, the fourth report of the Ball and Roller Bearings Division, was referred back to the society without discussion. Mr. Fergusson pointed out that the data at hand were not completed by any means and that the division has been trying for 3 years to collect the data for the limits of tolerances to be specified. The division desires to get all the manufacturers of these products together in order to fix these, but so far has been put off by them. It was suggested that the report of this division which is to be presented at the next winter meeting be a final report, for in this way the manufacturers could no longer put the society off on the matter, as Mr. Birdsall put it.

Chairman W. P. Kennedy was not prepared to submit its report as there is a large amount of research work to be done on account of the rapid progress of the truck industry and the widely-varying designs and practice. It will report at the next meeting.

The fifth report of the Broaches Division was submitted by its chairman, C. W. Spicer. It contains tables of specifications for six and ten-spline shafts. This report was referred back to the committee for further consideration of the proportions for multiple-splined shafts.

Progress on Passenger Car Wheels

The Passenger Car Wheels Division, which was formed at the last winter meeting of the society and which held a meeting with the rim makers in Cleveland in the earlier part of the year, reported progress. It has found the need of data as to the strength of rims. The weight and material of which rims are made are coming more to the attention of the division. In order to obtain data as to the strength necessary for the rims, two rubber companies came forward at the meeting and volunteered to test the force exerted by the tires by blowing them up until they burst. The figures thus gathered will give the committee something to work on.

As a further evidence of the progress of the division, it was stated by Chairman Henry Souther that already several makes of demountable rims have been so modified that they will all go on the same felloe bands.

No report of the Motor Testing Division was presented by Chairman John O. Heinze, although progress is being made. Before making another report the division wished to get the views expressed by the visiting Britons as to testing methods in order than any valuable suggestions might be incorporated in the next report.

George W. Houk, who read the interesting paper on wire wheels

than the first-class wood wheels. When weight was taken into account the wire wheel's superiority was incontestable.

A number of members of the American Society of Automobile Engineers were present at the Rudge-Whitworth works in Coventry in November, 1911. The test carried out at that time was on an English artillery wheel, made from oak. Results were so overwhelmingly in favor of the wire wheel that some of the members did not feel that the English artillery wheel was as strong made of oak as the American wheel made of hickory.

Rudge-Whitworth procured the best American hickory wheel, made by one of the most reputable makers in this country. Both wheels being 34 by 4.5, with tire inflated to 80 pounds pressure; the wire wheel complete with inner hub weigbed 92.25 pounds; the wood wheel 136.25 pounds. The pendulum bob weighed 450 pounds. The pendulum hob was pulled back at different distances up to 6 feet and released.

An equal number of blows were struck, resulting in the complete destruction of the wood wheel, while the wire wheel was still in condition to be used.

Wire Wheels Are Savers of Tires

Wire wheels show a great saving in tires. Many claims are made why this is so. Taking them in the order they would appear to the layman they are:

FIRST—WEIGHT: A 36 by 4.5 R. W. wire wheel with Houk Q. D. rim, weighs 57.25 pounds, inclusive of inner hub, the hub weighing 23.25 pounds, spokes 5 pounds, rim and nipples 29 pounds. The same size American hickory wheel with demountable rim weighs 101.25 pounds, wood felloe, 5 pounds; spokes, 9 pounds; felloe band, 21 pounds; rim, 36.5 pounds; wedges and nuts, 7 pounds; hub, 22.75 pounds. Therefore, the excess weight of the wood wheel as compared with the wire wheel is found at the periphery of the wheel.

This may be said to have a very serious effect on tires; in addition, the double thickness of felloe band and rim, backed by the wood felloe, retains the heat, so detrimental to tires, while the seventy spokes and naked rim of the wire wheel radiate the heat.

SECOND—RESILIENCY: That is, resiliency in the direction in which the load is carried; it may be said to relieve the strain on the tires, both in starting and stopping.

Actual figures showing tire saving are very difficult to obtain, as pneumatic tires are extremely variable in their performances. However, we have a concrete example in the Daimler company's hiring department in London. Fifty tires were tested on wood wheel and fifty tires on wire wheels, attached to identically the same cars. The wood wheels traveled 102,524 miles, an average of 2,050 miles per tire. The wire wheels traveled 172,731 miles, an average of 3,454 miles per tire. This clearly shows an increased mileage of over 70 per cent., or what is equivalent to a reduction in your tire bill of 40 per cent.

The growth in the use of wire wheels in Europe for both pleasure and racing cars is proof conclusive that the wire wheel has come to stay. From the day of the Gordon-Bennett trials in Ireland, to the ruling out of detachable wheel cars by the Grand Prix authorities because of an undue advantage thereby enjoyed, to the subsequent Grand Prix race, in which thirty-one out of thirty-six cars were detachable wire wheel equipped, to the present day when more than 60 per cent. of all Europe and British production of motor cars is detachable wire wheel equipped to the conditions here in the United States to-day, when leading makers of motor cars are offering as optional causing spokes to break and loosen and the wire wheel to be brought into disrepute.

The fundamental reasons for this sure and steady progress may be stated as follows:

1—Saving of weight.	4—Better riding qualities.
2—Increased safety.	5—Improved appearance.
3—Increased tire life.	6—Growing scarcity of suitable wood.

First-class wire wheels, owing to their construction, which not only embodies the most careful selection of materials as well as the highest grade workmanship, cost at the present time from one-third to one-half more than the best wood wheels. Starting with the inner hub, machined from a solid steel bar or a drop forging, it must be accurately machined to take the bearings, as well as to be interchangeable with all five wheels, so that they may be easily detached and attached without allowing the slightest bit of play to cause squeaking or chucking, so common in most demountable rims.

Further than this, we have a great variety of axles in this country, and to produce an inner hub capable of adapting itself to the fixed axle, as well as the floating type with the driving dog requiring at least a 5-inch inside diameter, it was necessary for the company to produce a hub suitable for the smallest to the largest diameter axles, ranging from 2.75 to 5.5 inches, and at the same time to be interchangeable, as well as secure by a locking device that would permit of readily detaching as well as attaching the wheel to the hub. In most practices of attaching the outer shell to the inner hub it was accomplished by a fixed locking device, usually on the order of ratchets and springs. This fixed locking device did not find favor in the hands of the public because the serrations were liable to wear as well as because of the accumulation of dirt and the failure of springs.

This resulted in giving great attention to the development and perfection of the automatic locking device, which in spite of neglect on the part of the chauffeur would not cause harm or trouble.

The 1913 locking device consists of a threaded lock ring with a v-shaped groove. This groove locks on the outer end of the hub. When this nut is slack the pressure on the groove face occurs at a point, by reason of the outer shell being larger than the inner hub. Therefore, the weight of the car produces an eccentric differential creep, whereby the nut lags and so tightens itself against the hub shell. When perfectly tight the nut is concentric with hub shell and creep ceases.

This feature might be more easily explained by taking the opposite view of the nut on a buggy wheel, wherein a left hand nut is fitted to the left hand side of the buggy and a right hand nut to the right hand side; more easily understood by the well-known fact of a ball or roller traveling the reverse way in which the object it carries is going.

Wire spokes were extensively used in connection with the earlier stages of automobile construction with more or less success, but this was due largely to the light weights they had to carry. As the weight of the car increased, the general supposition was they should increase the thickness of the spoke. Experience proved that this theory was entirely wrong. The Lanchester company of Birmingham adopted a comparatively thin spoke of suitable material, but with careful thought given to the bend in the spoke, so that it would leave the hub shell and rim in such a manner that it would allow for elongation without causing the nipple heads to leave the seat of the rim, or the heads of the spokes to leave the seat of the hub shell when the wheel came in contact with an obstruction.

Many months of careful experimenting and road testing served to solve the problem, resulting in the Rudge-Whitworth triple-spoked wheel, which overcame the weakness of the side strains to which a wheel might be subjected in leaving a rut or crossing a car track. Special machinery had to be invented and perfected to depress the rims, as each size of hub shell and rim required a different angle. The same may be said of the bend of the spoke leaving the hub shell.

120 millimeter hub fitted to a 36 by 4.5 rim would require a different bend in the spoke as well as a different angle from

which the nipple seated into the rim, as compared with a 62 millimeter shell and a 36 by 4.5 rim.

We find to-day one or two advocates of the substitution of wire wheels for existing cars, now fitted with wood wheels, urging the local garage men to purchase hubs, rims, spokes and to assemble these to fit the job. This is bound to result in linking together the hub and rim at wrong angles, thereby causing spokes to break and loosen and the wire wheel to be brought into disrepute.

Marmon Opens Discussion

In opening the discussion, President Howard Marmon stated a fact which he had observed in connection with the recent 500-mile race at Indianapolis, and which he would like to have answered by an authority. Although the race was won on wire wheels, two of the teams changed over to wood wheels after practicing and before entering the race, the reason given being that the front wheels in rounding turns at speeds 80 miles an hour, knuckled under so as to interfere with the steering.

J. G. Vincent, Packard company, stated that in his opinion the demountable feature is the greatest advantage of the wire wheel. Next to this there is the tire saving, a wire-wheel-equipped touring car has 78 pounds less weight than with wood wheels, considering two spare tires for the latter and extra wheels in the former case. It is more difficult, however, to carry extra wheels than tires alone, which may be carried at the side. Mr. Vincent has found some difficulty in getting garages to wash the wire wheels except at extra cost. He did not agree with one of Mr. Houck's statements that wire wheels get through mud and mire easier, since he has found that the larger wood spokes give greater surface for traction in deep mud, the wire spokes filling up and giving the wheels the appearance of steel disk types, which then slip in the mud.

The finish coming off the wire spokes, thus allowing them to rust, is a serious disadvantage, according to Mr. Vincent. It is very hard to get the enamel to stay on, but the new process of coating them as touched upon by Mr. Houk may be an effective remedy. As to tire saving, he does not know what that will be yet, and as regards riding, he states that it is impossible to tell the difference between riding on wood or wire wheels.

F. E. Muscovics asked if there were any difference in the accelerating powers of the car equipped with wire wheels provided that the weights were nearly the same. Mr. Vincent replied that he had tried acceleration tests on both wire and wood wheel cars for the purposes of comparison, but got no results which showed a difference in favor of either one.

David Fergusson, stated that the Pierce-Arrow company had also run a series of tests lasting over 18 months in order to determine whether there was any advantage in this respect which could be credited to the wire wheel. He stated that no difference was found.

President Browne, of the I. A. E., stated that he had personal experience with the wire wheel and that he found a decided saving of tires in favor of the wire wheel. He said that, whereas he got about 5,000 miles out of a casing in connection with wire wheels, his mileage on the wood wheels amounted to only 3,500 miles. He stated that the cleaning trouble was not serious and that the enamel did not get knocked off ordinarily. His chauffeur at first disliked the idea of cleaning the wire wheels but soon learned to do it and it took him but little longer than necessary to clean the wood wheels.

Mr. Moscovics stated that he thought the difference in acceleration due to the use of wire wheels might be more noticeable in the lighter cars.

Mr. Hall remarked that as a tire maker his company had carried on a long series of experiments, but as yet could say nothing except that the results were much different than they had expected. This ambiguous statement was the cause of considerable mirth among the engineers present.

Humber to Abandon Wire Wheels

Mr. Benson of the English Humber Company made some remarks that were of the greatest interest, especially since his concern has been using the wire wheels for the past few seasons. He stated that the wire wheels were to be abandoned by his concern and that the 1914 Humber cars would be equipped with artillery wheels of hollow steel construction. He stated that this determination was reached after circularizing the dealers. He stated that out of 150 who had received the letters asking their opinion on the wheel question, 140 replied in favor of abandoning the wire type. The arguments against the wire wheel as used by the dealers were difficulties of cleaning and rusting between the valve hole and rim. Mr. Benson stated that he did not think there was any difference in the accelerating qualities in favor of either type of wheel.

President Marmon asked Mr. Benson if his company would use the demountable type of rim. He replied that his company would use an entirely different wheel of detachable type.

Mr. Clarkson, of the I. A. E., asked Mr. Houk regarding the Sherardising and other processes for preventing the wire spokes from rusting to which Mr. Houk replied that he was not using the process.

Mr. Mott stated that it was his belief that the weight of the wheel depended to a very large extent on the type of rim that was being used. He stated that with some types of rim the wire wheel would be heavier than the wood wheel; or, conversely, that the artillery wheel with certain types of artillery wheel rim would make that wheel lighter than some of the standard types of wire wheels.

Mr. Wheeler stated that rust was not of much importance if the operator knew the processes for rendering the wheel metal rust-proof. The entire matter, he said, could be expressed in the two words used by H. M. Leland, "knowing how."

Mr. Bennett, of the I. A. E., spoke on the decline of the wire wheel in England. He stated that it was gradually passing out. This year, he said, there were 20 per cent. less wire wheels sold than last year. In regard to the American tires he stated that he had noticed that the American tires blew out much more frequently than the English tire. He stated that this was due to the entrance of water through the aperture of the rims, thus rotting the fabrics. He stated further that he believed the wire-wheeled-car to be much more lively than the car using wood wheels. Mr. Bennett called attention to the Victor car tire test which was run in England some time ago wheen steel studded tires stood up well. His mention of the steel studded tire was caused by T. B. Browne stating that in his experience with the steel studded tire he did get a very good mileage.

W. G. Wall stated that in his opinion the entire question of the success of the wire wheel was one of initial design. He stated that the English engineer was working against different conditions than the American. He stated that the strength tests made on the wood wheel in England were made with a poor quality of hickory and that the good second-growth stock would have shown much better results than were obtained with the material tested out in England. A great drawback with the wire wheel as it now stands was stated by Mr. Wall to be the bad locks that are in use. He stated that he knew of one car where all four locks were broken just before the race at Indianapolis. On the whole, Mr. Wall is in favor of the wood wheel.

Henry Souther was then called upon by Mr. Marmon to close the discussion. He stated that at one time he held an absolutely unbiased opinion on wire wheels, but now since he had become interested in them that opinion had become decidedly biased in his favor of them. He liked them, he said, because of the ease in making a tire change. The rust problem is important, he admitted, but this could be easily brought under control by the use of the spare wheel which would allow a wheel that was threatened by rust to be taken off and enameled. The enameling work can be done in a short time, and it is easy and inexpensive.

P. W. Litchfield, who presented the important paper on tires

Pneumatic Tires

From Paper Read Before the S. A. E. and Visiting Engineers by P. W. Litchfield

THE manufacture of pneumatic tires, an industry less than 25 years old, has grown until at the present time the value of its product in the United States alone amounts to about $150,000,000 annually.

It has been the practice of automobile and vehicle builders for many years to make as nearly as possible the entire vehicle, but while the pneumatic tire is a component part of every vehicle, no manufacturer of bicycles, motorcycles or automobiles has ever successfully made his own tires, and the number of tire manufacturers has always been relatively very small compared with the volume of the industry.

If we go back to about the year 1890 and look at the means of transportation in vogue, we find that the hauling by self-propelled vehivles on land was confined to the railroads, two smooth parallel rails being carefully laid to form a perfect road-bed to protect the machinery of the locomotive sufficiently to make it a practical commercial proposition. The millions of ordinary roads throughout the country were used for hauling by means of domestic animals only.

At about this time the safety bicycle and rubber tire were developed. This brought to the attention of everyone the simplicity, speed and healthful exercise to be obtained by abandoning the horse and propelling the vehicle by man-power. While the horse could not call attention to the weaknesses of the vehicle which made his work harder and his progress slower, man, when he assumed the duties of the horse, began to analyze. Then began the study and development of the self-propelled vehicle industry of today.

Let us go back to the man on the bicycle. He soon found out that the solid tire was satisfactory on a smooth road, but when it came to a rough road he could feel the bumps and had to slow down, as the impact of the tire against stones and uneven surfaces was more than he could stand with comfort and more than he could propel the bicycle against with his own power for any length of time. Naturally, his next idea was to get more cushion. This resulted in the introduction of the cushion bicycle tire, which was an all-rubber tire with a hole in the center to allow for more distortion in the rubber itself, the cross-section diameter of the tire being increased from .75-inch to about 1.5 inches. The rider then found he had gained more cushion, but had increased the weight of his vehicle, so that it required more power to propel the bicycle on good roads. It was at this time that

J. B. Dunlop, inventor of the pneumatic tire, who took part in the discussion of Mr. Litchfield's paper

the pneumatic tire was invented to increase the cushion, decrease the weight and lessen the power consumption of the tire on ordinary roads. Since about 1893 the only tires which have been used on self-propelled vehicles are either solid rubber or pneumatic rubber tires; no other type seems at the present time likely to engage the serious attention of engineers.

As both of the above-named types are being used in larger quantities every day, let us (before passing to the pneumatic) analyze the difference between them and see under what conditions on seems to be superior to the other. This brings us to the question: In a self-propelled vehicle, what are the functions of the tire? They are, first, and foremost, a cushion to protect all parts of the vehicle from the shock caused by the impact against inequalities of the road; second, to provide proper traction, avoiding unnecessary slip. These are the two main functions, and, therefore, the principal thing to be kept in mind in tire design is to satisfactorily accomplish them at as low a cost per vehicle mile as possible, with the least possible consumption of power, and with the least amount of trouble and inconvenience to the driver and occupants. The pneumatic tire depends upon the elasticity or resiliency of a gas, *i. e.*, air, for its cushioning effect, while the solid tire depends upon the resiliency of a practically incompressible solid (*i. e.*, vulcanized rubber). It is needless to say that air is the more perfect cushion and the lighter and cheaper, the cost lying only in the air container. No other *solid* body can compete with india rubber in acting as a cushion by being greatly distorted and recovering its original shape again repeatedly with very little fatigue.

Vulcanized Rubber Is Incompressible

One point regarding rubber must be carefully borne in mind, which is, that vulcanized rubber is practically incompressible; its cushioning effect is only possible by distortion and recovery, and it must be allowed by the designer plenty of room for this action. A glance at hundreds of patents on solid-rubber tires shows that this point has been almost entirely ignored by inventors. Another point frequently overlooked is that the shock may come from almost any direction, owing to varying road surfaces, turning corners, running into curbstones, etc. Many tires and spring wheels carefully designed to take up blows acting directly from the ground vertically toward the rim are utterly unfit to withstand shocks in other directions.

Before selecting between the solid and pneumatic tire, the weight to be carried, the speed to be attained, and the character of the road must be considered. The load to be carried can be worked out satisfactorily on either type. In a solid tire it requires a sufficient amount of properly compounded rubber, and in a pneumatic a sufficient combination of air volume and pressure contained in a suitable retainer. The character of the road and the speed have a great deal to with the selection of type, as air being a much better cushion than rubber, allows the pneumatic to give much more efficient cushion and traction on rough roads and at higher speeds than is possible for the solid. As far as the efficiency of the vehicle is concerned, the pneumatic would nearly always be chosen as the ideal tire were it not for the fact that in many cases the roads are sufficiently good and the necessary speed sufficiently slow to make the saving in cost per mile on solid tires, due to their longer life, offset the increased efficiency of the pneumatic. Again, the unreliability of the pneumatic due to injury through punctures or blowouts, making attention to it necessary at awkward places and times, often causes the selection of solid tires, as frequently occurs on pleasure electrics for ladies, fire apparatus, mail wagons, etc. In short, good roads and slow speeds are favorable conditions for solid tires; ordinary roads and high speeds for pneumatic tires. The solid tire having less cushion and less motion requires a lower percentage of pure rubber in its composition than the pneumatic, which tends to lower tire mileage cost.

Three Types of Pneumatics

To go back again to the man on the bicycle. His experience with solid and cushion tires resulted in the invention of three types of pneumatic tires at almost the same time, and these three have been the only ones that have been, or are now, used in any quantities. They are the single-tube, invented by Tillinghast; the clincher, invented by Bartlett, and the wired-on, invented by Dunlop. There was great rivalry between the thre types for 2 or 3 years, resulting in the supremacy of the single-tube in the United States and the clincher and wired-on types in all other parts of the world. The introduction of quick-repair cements, of single-tube repair shops all over the country, and lower cost of production were largely responsible for the success of the single-tube in this country. The wired-on type is still the most popular in other countries.

Following the pneumatic bicycle tire came the pneumatic carriage tire, and each country developed the type of tire found most popular on bicycles. This was a temporary business, however, because the tires were used on horse-drawn vehicles, they did not have to perform the traction or driving functions, and the speed of the horse was so slow that a sufficient amount of cushion could be obtained from solid tires and metal springs without the annoyance of punctures; hence this type of tire gradually gave way to the solid.

Following the pneumatic-tired carriage, about the year 1898, came the automobile with its delicate mechanism and high speed, and with it the demand for a more durable and efficient pneumatic tire. As in the case of the carriage, each country still further developed the type of tire which was most popular and successful on bicycles. American designers went ahead with the single-tube, making it up to 5 inches in size, while England developed the wired-on, and France the clincher, (the clincher was also being made by G. & J. and Goodrich in the United States). It did not take very long, however, to discover that conditions were quite different on the automobile from what they were on the bicycle, and the French clincher tire made by Michelin and others soon had all the other types "on the run," and English and American tires were at a discount. The wired-on type, which proved so successful on English bicycles, disappeared in the large sizes, because the one-piece Dunlop rim, which was so easy to fit with an inextensible-edge tire in small cross-sections, was almost an impossibility in large sizes. The single-tube American tire when made of a size and thickness necessary for an automobile could be repaired only at great expense and at a well-equipped repair shop. Roadside repairs were impossible. The clincher type soft bead tire was the only practical one of the three for an automobile, and soon became the standard of the world and was made in all countries. The weaknesses of this type of tire which developed were principally the difficulty of forcing the tire (in the large sizes) over the one-piece clincher rim; the necessity for several tire bolts to keep it from creeping on the rim, owing to the stretching of the bead; its depending entirely upon air pressure to hold it on properly; and when overloaded, or much underinflated, rim-cutting, and if run wholly deflated, destruction in a very short time. To overcome these difficulties several mechanically fastened side-flange and bolted-on type tires were introduced, but they required special wheels, special widths and diameters of felloe, were more expensive, and, with the exception of the Fisk bolted-on type, did not make much headway against the standardized clincher tire. The Clincher Automobile Tire Manufacturers' Association had wisely standardized the clincher rim dimensions and insisted on carefully inspecting all rims manufactured, saving the automobile owners and tire manufacturers hundreds of thousands of dollars, which would have been lost if the unstandardized condition, similar to that which now exists in Europe, had not been remedied.

During 5 years, from 1900 to 1905, the clincher tire was perfected and standardized. It seemed that it would have no competitor, but the last-named year brought out the invention of two quick detachable rims, the Dunlop and the Goodyear. They were developed to a point that they would fit the same wheels as the clincher rim, and by reversible rings, take either the clincher type of tire or the wire-bead type. These rims overcame, first, the difficulty of stretching the tire over the clincher rim, which was so difficult in large sizes; second, with the removable side ring the tire could be made with an inextensible bead, making it free from creeping by the use of only one bolt on the valve stem, instead of several at intervals around the tire; third, the beads being always against the rim, the inner tube was not so liable to be ruined, in case of puncture, by getting under the beads, and, fourth, a wired-on type could be used with the flanges turned outward, instead of hooked in, making rim injury to the tire less likely in case of overloading or underinflation. The flared-out side ring also made it easier to mount and remove the tire from the rim. This quick detachable type of rim became, a year or two later, the American standard and the wire-bead type of tire began to grow steadily in popularity.

The introduction of this wire-bead straight-side tire met with considerable opposition from the manufacturers of clincher tires, and in meeting it they introduced the quick detachable clincher type.

Vulcanization

I would now like to discuss some of the differences between the principal pneumatic tires now in the market. Let us first take up the subject of vulcanization. Vulcanization is the chemical change which is caused by the action of heat and time upon the mixture of rubber and its chemical compounding ingredients, transforming it from a plastic dough to a resilient and reacting solid. In order to get a properly vulcanized tire extreme care must be used as to the materials used in compounding, in regard to both quality and amount, and also as to time, temperature and conditions under which the vulcanization takes place. A tire revolving constantly along the road, carrying the weight of the car, and each moment changing its shape and recovering, generates a great deal of heat. This action of heat carried on for a considerable time has a tendency toward affecting the vulcanization. Therefore, all high-grade guaranteed tires are usually compounded so that they take a very long time to vulcanize. This increases the cost of manufacture. Many unguaranteed tires are so compounded that they vulcanize quickly, saving from one-half to three-quarters of this time, in order to cut down the cost, but the heat generated along the road tends to overvulcanize these tires and they are apt to separate and blow out after a much shorter mileage on this account.

Another difference in pneumatic tires is in the style of fabric used, there being two distinct types upon the market, the close-woven fabric tire and the cord tire. Nearly all tires are of the close-woven fabric type as they are more durable, easier to repair in case of injury, and can be operated at a much lower cost per mile.

The next point to consider is the size of the tire. In the pneumatic tire the load is carried by an air cushion, and the amount of the load carried depends upon the combination of the volume and pressure of air used. For a given weight of car it follows, therefore, that the larger the volume of air in the tires the less inflation pressure required, while the smaller the tire the greater the inflation pressure necessary to carry the load. Tires should be large enough to carry the load with very little flattening of the tire, say not over 14 per cent. of the sectional diameter at an inflation pressure which will give sufficient cushion to the vehicle.

The use of tire fillers is another question which has commanded the attention of automobilists, owing to the extensive advertising carried on by tire filler companies during the past year. A pneumatic tire casing is designed for use with compressed air; when it receives a blow or shock from an obstruction in the road, the blow is distributed all over the casing, owing to the support of the perfectly fluid air-cushion behind it, the tire absorbing the blow, turning it aside, with very little injury to the casing, except in very severe instances. When a filler is used, the blow is localized in the immediate proximity of the point at which it is received, and the strain falls in one place, thereby weakening the tire. Constant repetition of these blows causes the casing to gradually disintegrate and wear out. The fillers add considerably to the weight of the car, require a great deal more power to drive the car, and do not absorb the shocks to nearly the same extent as is the case of air.

Before closing I would like to touch upon the subject of rims for pneumatic tires, as it is of the greatest importance to the tire that it be fixed upon a properly designed rim. With clincher tires especially the exact contour of the hooks is of great importance, as it takes only a very little variation from the standard to completely ruin the tire. The proper design for the width between clinches on a clincher tire has been standardized at 60 per cent. of the nominal cross-section of the tire. It is the writer's opinion that the proper dimension for the width at the heel of the bead for the straight-side wired-on tire is 66.7 per cent. of the nominal cross-section of the tire, flaring outward

Arthur J. Slade, who brought out some interesting points in the discussion on tire efficiency

from the heel of the bead. The less the required flexing of the casing when the tire is overloaded or insufficiently inflated, and the larger the supporting surface given by the rim to the tire where the flexing occurs, the less the tendency toward rim-cutting. The ideal rim would give continuous support to the tire, especially where the tire leaves the rim on the sides. Split and open side rings should be avoided as far as possible. When split rims are used, it is also absolutely necessary that they be in perfect alignment.

Discussed with Applause

After Mr. Litchfield had read his paper, President Marmon stated that it was very fitting that on this occasion Mr. Dunlop, the inventor of the pneumatic tire, who accompanied the party, should say something on how he came to invent the tire. Mr. Dunlop rose amid great applause to address the interested audience. He said:

"Mr. Chairman and Gentlemen: I esteem it a great honor to be called upon to speak on this subject. Many misstatements have been made in relation to the invention of the pneumatic tire but as we say in Ireland, 'only one-half the lies that we hear going around are true.'

"I have always given great attention to the subject of traction and especially to road traction. I have always wanted something that would flatten out under the weight of the car in order to reduce the unit pressure on the part of the tire that is on the ground by increasing the area of contact. I first thought of flexible steel.

"A good many people have asked me what made me think of the pneumatic tire. I am only surprised that I did not think of it sooner."

Mr. Dunlop then went on to tell some of the details of manufacture of the earliest forms of his tire which was first patented in July, 1888. He stated that everyone knew that speed depends on resiliency, but strange to say the slowest tire that was ever made was the most resilient.

"Radial elasticity is necessary," stated Mr. Dunlop. "The pneumatic tire, although resilient, is rigid both in a circumferential and axial direction. If you take a piece of solid rubber and stand on it, it will flatten out, the sides will be widened and then when the load is removed they will creep back to normal. There is always a lump in front of a solid rubber tire just ahead of the axle center line. This is especially so in ascending a hill. This condition is not true of the pneumatic tire."

When Mr. Dunlop first proposed to make a broad tire that would be fast people said it was absurd as the fast tires of that time for bicycle work were about the thickness of the little finger.

When pneumatic tires were first manufactured, people used cloth cut on the bias for casings, but it was found that after a time the threads cut each other. The material used at that time was linen.

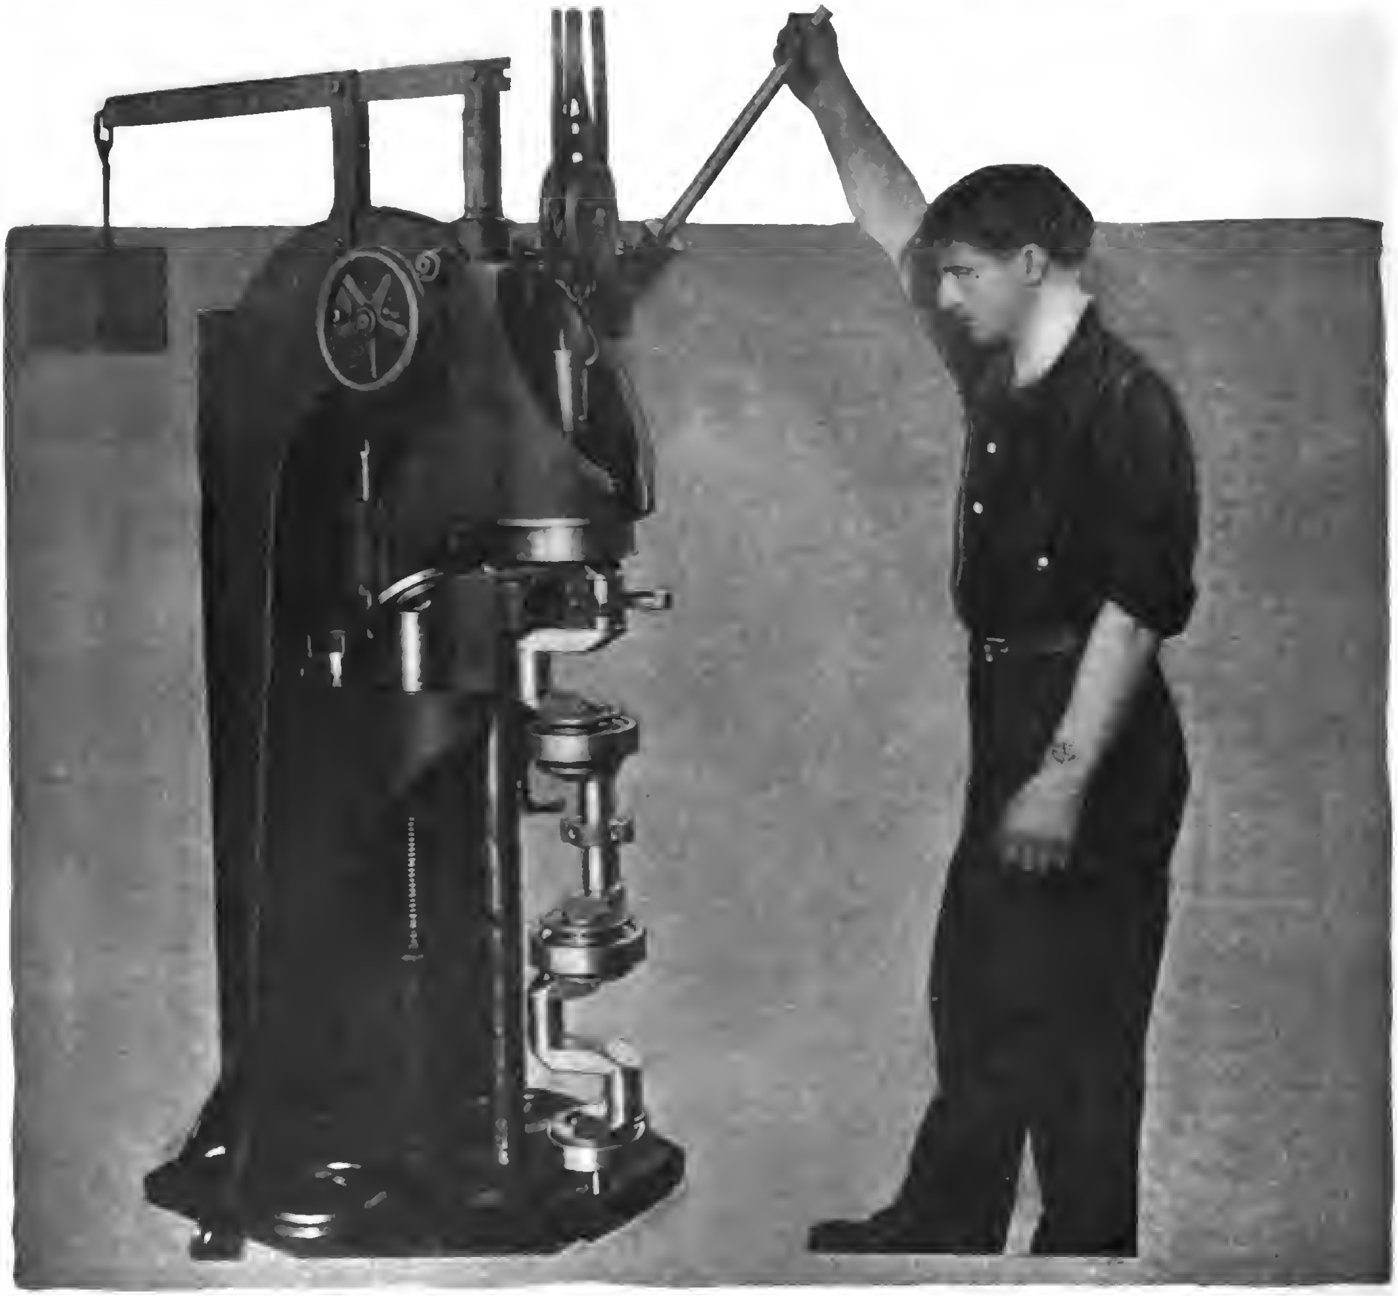
The first tire was made by making disks from a piece of wood cut off a plank and then wrapping the rubber which was secured in strips around the disks. To pump up the tires a football pump was used in connection with a piece of rubber hose from a nursing bottle. The tire tube although built up out of strips of 1-32-inch sheet rubber cemented together was air-tight. This thickness of rubber is still used in inner tube work. The first tire was built February 28, 1888. It was tried out in the moonlight and that night there was a partial eclipse of the moon.

A. J. Slade asked Mr. Litchfield if he were familiar with the different efficiencies of pneumatics, filled and solid tires at different speeds, to which the latter replied that he had no full set of figures although he had valuable data compiled from a long series of experiments. Mr. Slade remarked that he had noticed data sheets in the S. A. E. handbook which did not seem to be exhaustive or up-to-date.

C. H. Taylor asked if the cord tire were any more apt to have sidewall blowouts than any of the other types, to which Mr. Littlefield replied that he believed there was no difference.

Charles Wheeler, of the I. A. E., called attention to that part of Mr. Litchfield's paper which deals with fabric, and pointed out that while the cord tire is a speedier tire and makes for easier riding, it is more difficult to repair and in practice does not work out at as economical cost per mile as the close-woven type. Mr. Wheeler questioned this from the standpoint of the European countries where fuel runs up to 40 and 50 cents per gallon. He wondered from which viewpoint Mr. Litchfield's conclusion had been made.

Factory Miscellany



Special machine used for pressing ball bearings on Lozier crankshafts in the factory of the company, Detroit, Mich.

THE above illustration depicts the operation of pressing ball bearings on a Lozier crankshaft in the factory of the Lozier Motor Car Co., Detroit, Mich. Four annular ball bearings are used and the greatest accuracy is essential in pressing them on the shaft, but .0006 of an inch variation being allowed in the fit of the bearings. The special machine shown exerts a pressure of approximately 1 ton. The ball bearings on the center of the crankshaft are slipped over the crank cheeks, the inner race being large enough to permit of this. A split collar is pressed in between the shaft and bearing with the bearing against one of the crank cheeks. The bearing and collar are then pressed together to the center of the journal and a spacing collar is inserted on each side of the bearing. The rear bearing is put on first and then the others are put on in succession toward the front end. It takes 2 hours to assemble the crankshaft, it passing through only two hands in the process of assembling. The weight of the finished crankshaft complete with bearings is 140 pounds. It would be a very difficult task to press these bearings on the crankshafts without the aid of the special machine which also effects a considerable saving of labor, time and money.

DYNETO'S Four Story Building—The Dyneto recently erected a new factory at Syracuse, N. Y. It is a four-story brick building, with the boiler and engine room in a separate building. The building has a floor space of 30,000 square feet. It is equipped with new machinery throughout and is devoted entirely to the manufacture of electric starting and lighting systems. The capacity is 100 Entz electric starting and lighting systems and 200 Dyneto lighting systems per day.

Miami Plant in Indianapolis—The Miami Cycle & Mfg. Co., Middletown, O., is having a new plant erected at Indianapolis, Ind. The company makes motorcycles and accessories.

Mais Truck Plant Burns—Fire which burned itself out when fire-fighters were helpless for lack of water did $90,000 damages to the plant of the Mais Motor Truck Co., Indianapolis, Ind., recently.

Chicago Firm Moves—The Auto Sheet Metal Works, Chicago, Ill., recently moved into larger quarters at 1532 Michigan avenue, where it has a floor space of approximately 10,000 square feet.

Firestone Adds Four-Story Plant—The Firestone Tire & Rubber Co., Akron, O., has given out plans for the construction of a four-story brick, steel and reinforced concrete manufacturing plant addition.

Anguish Plant in Detroit—The Anguish Mfg. Co., Detroit, Mich., recently incorporated to manufacture metal stampings and automobile radiators, has acquired the plant and machinery of the Farlinger Mfg. Co., 1506 Fort St., that city.

Schram Automobile Plant—A plant for the manufacture of a new automobile to be named the Schram, will be established near Seattle, Wash., in the near future. A company for the manufacture of this machine was recently incorporated at $500,000 by F. J. Carvery.

Ready for Occupancy—The Cleveland Hardware Co., Cleveland, O., has completed its six-story addition and is ready for the installation of machinery. The company manufactures forgings and automobile parts.

Beulah Automobile Manufacturing City—W. W. Bennett, a wealthy Detroit, Mich., automobile manufacturer, has bought the orphanage colony town at Beulah, Tenn., near Nashville and will establish a new automobile manufacturing city.

Winton Workers Get Increase—The Winton Automobile Co., Cleveland, O., has granted an increase of 10 per cent to all its employees, numbering about 1,100. The reason for this increase is because of the fact that there are a considerable number of the employees members of the Automobile Workers' Union.

East Palestine Wants Rubber Plant—The Board of Trade of East Palestine, O., was voted unanimous support in its endeavor to secure a new rubber plant for that city. C. J. Davis and a few associates propose to build and operate a rubber tire manufacturing plant, 50 by 200 feet and two stories high.

Mogul Moves to St. Louis—A long lease that brings a new enterprise to St. Louis, Mo., was recently closed. The newcomer is the Mogul Motor Truck Co., Chicago, Ill. The lease covers the one-story structure, 100 by 165 feet. The company will abandon its Chicago factory and move to St. Louis this month.

Quarterly Output 1,000 Machines—The Crown Motor Car Co., Louisville, Ky., announces that it will turn out 1,000 machines during the next three months. The following year the Crown firm expects to make 50,000 cars. Whether the permanent plant of the company will be located in Louisville has not yet been decided.

Goodyear Cotton Mill—The latest step in the growth of the Goodyear Tire & Rubber Co. is the purchase of a large tract of ground in the heart of the cotton district known as Williamsville, Conn. On the property is a large cotton mill, four stories high and 400 feet long, where will be made a large part of the tire fabrics, hose and belting ducks so extensively used by the company. There are also on the property houses to care for 350 employees, a church, a schoolhouse, etc.

Metz Building—The Metz Co., Waltham, Mass., manufacturer of the Metz car, is building an addition to its present plant containing 90,000 square feet of floor space. Last year this company added 26,000 square feet of floor space to its plant. The present volume of business is the largest enjoyed in the history of this company, as shown by the fact that every department is being operated to its greatest producing capacity at the present time, and both day and night shifts are working.

Showa, Conventions, Etc.

October 13........Pbiladelpbia, Pa., National Fire Prevention Conference, Philadelphia Fire Prevention Commission.

December 9-12......Philadelphia, Pa., Annnal Convention of American Road Builders' Association.

Race Meets, Runa, Hill Climba, Etc.

Jnne 14...........Cincinnati, O., Hill Climb, Cincinnati Auto Dealers.

June 14-15........San Francisco, Cal., Track Races, E. A. Moross.

New factory of the Dyneto Electric Co., Syracuse, N. Y.

The Week in the Industry

Engineer — Dealer — Repairman — Garage

Test cars furnished by the Henderson Motor Car Co., Indianapolis, Ind., during the recent 500-mile race at Indianapolis

Road scene of the Twin City-Glacier Park Automobile Tour

On the road to the top of Royal Gorge, Canon City, Col.

HENDERSONS HELP INDIANAPOLIS GUARDS.—The above illustration shows the six cars furnished Speedway management at Indianapolis, Ind., at the recent 500-mile race, by the Henderson Motor Car Co. A soldier rode with each tester throughout the day, and after the race started the police cars were put in the infield to keep the crowds well in hand in case of accident. The many automobiles that came to the race congested all the roads to the Speedway, and the guards of the course were placed on the road early in the morning and after the race to keep the cars moving without confusion. Handling such a crowd as gathers for the annual 500-mile race at the Indianapolis Motor Speedway is no small task.

MANITOWOC GARAGE CHANGES HANDS—The garage and repair shop of S. F. Splitt at Manitowoc, Wis., has been purchased by Ullius & Bernstein, of Milwaukee.

IDEAL TRIP THROUGH ARIZONA—The Franklin Automobile Co., Syracuse, N. Y., has recently issued a twenty-page booklet on a wonderful trip made by one of its cars through the Grand Canyon of Arizona.

NATIONAL ORGANIZED IN 1900—In the May 29 issue of THE AUTOMOBILE an error was made in stating that the National Motor Vehicle Co., Indianapolis, Ind., was organized in 1904, when it should have stated in 1900.

BY WAY OF CORRECTION—In the May 29 issue of THE AUTOMOBILE a picture was captioned Massive Exhaust Manifold of De Palma's Mercedes. It should have been Mercer. In the June 5 issue a picture captioned A Snapshot of Jenkins in His Schacht, Taken Just Before the Great Contest Began, should have been, Spencer Wishart in the Mercer which Finished Second.

BUFFALO'S AMPHIBIOUS GARAGE—The Amphibious Garage Co., Buffalo, N. Y., is having plans drawn for the construction of a garage for automobiles and motor boats on the Jones property, between Ontario street and Riverside Park. This company has leased 1,200 feet of water front on the Niagara River and a portion of the uplands facing Niagara street, on which the entrance to the garage will be located.

BOSCH ESTABLISHES DISTRIBUTORS—The following stations have been appointed by the Bosch Magneto Co., New York City: S. S. Marmalee Co., Macon, Ga.; Lackawanna Automobile Co., Scranton, Pa.; Armstrong Auto Co., St. Joseph, Mo.; Electric Mfg. Co., St. Paul, Minn.; Edwards & Dickey, Portsmouth, N. H.; Susquehanna Motor Car Co., Wilkes-Barre, Pa.; J. F. Esser, Flushing, N. Y.; Spokane Cycle & Supply Co., Spokane, Wash.

MOTOMETERS ON INDIANAPOLIS RACERS—The following cars used a Motometer in the recent Indianapolis, Ind., race: De Palma, Bragg and Wishart's Mercers, the two Peugeots, three Case cars, two Masons, Clark's Tulsa, Liesaw's Anel, Pilette's Mercedes Knight, the three Isottas and the Nyberg, Keeton, Schacht and Henderson. The Motometer is manufactured by the Motometer Co., Inc., New York City, and is used as a radiator heat indicator.

CHINA'S AUTOMOBILE TRUCK ROAD—Chinese engineers, under the direction of J. G. Wong, an American-trained engineer, have been in Hongkong for some time making arrangements for commencing the survey of an automobile truck road in Kwangtung Province, which is designated as a feeder for the Kwantung section of the Canton-Hankow Railway and also probably as the beginning of a railway in connection with that truck line. The road will be about 100 miles long. It is planned to give the new road considerable hard surface dressing and to build substantial bridges, though no very important bridges will probably be needed on the enterprise planned at present. No decision has been reached as yet as to automobile or other trucks to be used, the expectancy being that the road as finished will be used for drawn vehicles for the time being. The company undertaking the enterprise is composed of Chinese capitalists who expect to begin operations in the near future.

Spare with Foss-Hughes—R. Y. Spare, formerly sales manager of the Oldsmobile Co., Philadelphia, Pa., has joined the Foss-Hughes Co., that city.

Receiver for Philadelphia Firm—J. M. Lutz has been appointed receiver of the Automobile Service Assn., incorporated with security fixed at $5,000.

Now In New Home—The W. B. Hollander Co., agent for the Metz car in Rhode Island, has just moved into its new salesrooms at 314 Broad street, Providence, R. I.

Mais Resigns from Studebaker—A. F. Mals has resigned as consulting engineer of the Studebaker Corp., Detroit, Mich. He will take a month's vacation before entering upon other employment.

Going Into New Quarters—Bunker & Reopell, now located on Fort street, Springfield, Mass., handling several lines of cars, will move into new quarters in upper State street in a few weeks.

To Fight Gasoline Cost—The Missouri Engine Co., St. Louis, Mo., recently incorporated, which proposes to combat the high price of gasoline, will engage in the manufacture of coal oil engines.

New Ford Building—Dutee Wilcox Flint, who handles the Ford line in Rhode Island, is having built a new service station and salesrooms on Allen avenue, Providence, that will be ready shortly.

Elliott Secretary of Travel Club—F. H. Elliott has been elected to membership on the board of governors of the International Travel Club, New York City, and also as general secretary of the club.

Calderwood Locomobile Assistant Manager—F. A. Calderwood, assistant manager of the Lozier Motor Co. of New England, recently severed his connection with that company to accept a similar position with the Locomobile Company of America at its Boston, Mass., branch.

Seiberling Haynes General Manager—A. G. Seiberling, for the past year factory manager of the Haynes Automobile Co., Kokomo, Ind., has succeeded C. B. Warren as general manager of the company.

Sim Joins Timken—F. N. Sim, formerly of the Burroughs Adding Machine Co., Detroit, Mich., has become assistant advertising manager of the Timken-Detroit Axle Co., and Timken Roller Bearing Co., that city.

Opens Knight Tire Agency—Manager Thomas J. Harris has opened up the Knight Rubber Co., on Madison avenue, Toledo, O. His complete stock of Knight tires has arrived and the machinery and equipment for the repair department has been installed.

Assets and Real Estate Sold—At a meeting of stockholders in Toledo, O., recently a portion of the real estate and assets of the Castle Lamp Co. were sold to J. N. Willys, president of the Willys-Overland Automobile Co. The Castle Co. is still in existence.

Big Addition for Garage—A $30,000 addition to the Norcross-Cameron garage in Springfield, Mass., will be made in the near future. The new part of the building will be 55 by 79 feet and will be four stories in height. It is to be of brick, concrete and steel.

Moves Into New Quarters—The J. C. Brown Co., of Providence, R. I., doing a general accessory business at 17 Washington street, opposite City Hall, has moved into new quarters at 19 Dorrance street, which places it among the dealers in the motor center of the city.

Williams Goes to Providence—The Alco Co. has decided to open salesrooms for its cars and trucks at Providence, R. I., and A. G. Williams, of New York, has been sent there to take charge of the branch. It was formerly an agency there handled by Frank J. McCaw.

Partnership Dissolved—George F. Howe and Wilbert L. Allen, who have been in business together for some years as the Brockton, Mass., Garage Co., have dissolved partnership, Mr. Howe going into the jewelry business while Mr. Allen will continue the motor establishment.

Wintons As Stages—From Northern British Columbia to Montana, Winton sixes are being operated daily on stage runs. Operating between Ravalli and Polson in Montana are three Wintons. They cover 122 miles each day and traverse all descriptions of roads and trails, composed largely of sand and rock.

Ford's New Philadelphia House—The Ford Motor Co., Detroit, Mich., has purchased a plot of ground at the northwest corner of Broad street and Lehigh avenue, Philadelphia, Pa., 370 x 231 feet, on which the purchasers will build one of the largest automobile factories and salesrooms in the city. The ground is assessed at $72,000.

Penniman in Charge Now—L. W. Penniman, for some time in charge of the sales department of the Walpole Tire Co.'s branch in Boston, Mass., has just been promoted to general manager of the teritory to succeed E. P. Weber, who resigned recently. Mr. Penniman was for some years manager of the Portland, Me., branch of the Goodyear Tire & Rubber Co.

Cadillac's Providence Service Station—The Cadillac Motor Car Co., Detroit, Mich., is planning a service station in Providence, R. I., which will be two stories, 65 x 95 feet, of steel beam construction and concrete foundation, brick with copper trimmings and gravel roof. An elevator, 22 x 10 feet, a sprinkler system, electric lights and steam heat will be installed.

Trade Changes in Portland—A number of trade changes took place in Portland, Ore., during the past week. The Gibson Storage Battery Co. moved into its new garage at 12th and Alder streets; the Michigan Auto & Buggy Co. moved to the west side, to 514 Alder street, and E. E. Gerlinger has issued plans for a new garage which will face on Washington, Morrison and Stont streets.

But Four American Cars Shown—At a recent display of automobiles in a fair in Montevidio, Uruguay, there were but four American cars shown. Twenty-three European cars were on exhibition. The dealers in French and German cars featured price lists of their repair parts and asked prospective customers to compare them with prices of other cars. Full stocks of repair parts are carried in stock, which is another advantage claimed over American and English cars.

Packard's May Shipment Large—Shipments of Packard vehicles in May make the largest total for any single month in the history of the Packard Motor Car Co., Detroit, Mich. Motor carriages and trucks representing a value of $3,237,945 were delivered to purchasers. This sum, compared with the best previous record of $2,748,750 made in April of this year, shows an increase of almost half a million dollars. The total business for the two months was approximately $6,000,000.

Automobile Salesroom Leased—Leases have been signed by the Peerless Motor Co., Philadelphia, Pa., by the International Truck Co. and by the Garford Truck Co. for the three large automobile warehouses and salesrooms which are being built on the south side of Chestnut street, west of 23d street. The leases are all for 10 years. The building at 2304 Chestnut street, containing 40,000 square feet, has been leased to the International Truck Co.; 2310 Chestnut street has been leased to the Garford Truck Co., and 2314 Chestnut street, with 105 South 24th street, containing about 35,000 square feet, will be occupied by the Peerless Motor Co.

New salesroom and service station of the White Co., 216 North Broad St., Philadelphia, Pa., which is up-to-date in all of its facilities

Ohio electric, a product of the Ohio Electric Car Co., Toledo, Ohio, recently given by the Canadian legislators to Mrs. R. L. Borden, wife of the present Canadian Premier, as a token of their esteem for her interest in Canadian affairs

The fine points of motor assembly being demonstrated at the service convention at the factory of the American Locomotive Co. of America, in Providence, R. I., recently, where employees from all parts of the country congregated

Recent Incorporations in the Automobile Field

AUTOMOBILES AND PARTS

BRITTON, OKLA.—Darling Automobile Mfg. Co.; capital $25,000; to manufacture and deal in automobiles and internal combustion engines. Incorporators: C. P. Stealey, W. A. Hegbe, H. C. Crum.

CLEVELAND, O.—Haupt Co.; capital; to deal in automobiles. Incorporators: H. A. Couse, R. G. Curren, Mary McManus, Alfred Clum.

CLEVELAND, O.—H. & H. Auto Co.; capital, $10,000; to manufacture and deal in motor vehicles. Incorporators: F. M. Fogarty, J. G. Fordyce, A. B. Brackenridge, H. M. Riedel, G. M. Dolan.

GUTHRIE, OKLA.—Stapleton Motor Sales Co.; capital, $2,000; to deal in automobiles.

LITTLE ROCK, ARK.—Arkansas Automobile Exchange; capital, $5,000. Incorporators: Sam Yout, Estelle Yout, S. J. Fecbbeck.

LITTLE ROCK, ARK.—Paige-Detroit Auto Co.; capital, $101,000; to deal in automobiles.

MAYSVILLE, KY.—Brown Auto Co.; capital, $4,500; to deal in automobiles. Incorporators: Mike Brown, W. B. Tully, B. M. King.

NEW YORK CITY—A. Estelmann Co.; capital, $15,000; to deal in engines. Incorporators: H. A. Bell, August Estelmann, P. A. Warnacke.

NEW YORK CITY—Lurie Auto Co.; capital, $1,000; to deal in automobiles. Incorporators C. U. Backer, S. S. Rosen, I. R. Caplan.

NEW YORK CITY—Rich Motor Co.; capital, $2,000; to deal in automobiles. Incorporators: B. A. Rich, G. P. Harvey, De Witt Fox.

OKLAHOMA CITY, OKLA.—Auto Repair Co.; capital, $2,500; to deal in automobiles. Incorporators: F. P. Fisher, J. H. Brennan, W. M. Davis.

PIERRE, S. D.—Gerling Mfg. Co.; to manufacture gasoline engines. Incorporators: F. A. Gerling, J. P. Minick, F. S. Winslaw, John A. Holmes.

RICHMOND, VA.—Alsop Motor Co.; capital, $5,000; to manufacture and deal in automobiles. Incorporators: J. B. Alsop, C. Armentrout.

SHREVEPORT, LA.—Southern Motor Co.; capital, $10,000; to deal in automobiles.

ST. LOUIS, MO.—G. M. Automobile Co.; capital, $5,000; to deal in automobiles. Incorporators: Robert Fritschle, E. E. Schoening, H. F. Glamann.

ST. LOUIS, MO.—Grand-St. Louis Auto Co.; capital, $4,000. Incorporators: Leon B. Scherrer, John J. Scherrer, Jr., F. A. Stosberg, A. W. Michaels.

TOPEKA, KAN.—West Motor Car Co.; to handle automobiles. Incorporators: J. E. Polley, F. Langley, L. Langley, H. G. West.

WAHPETON, N. D.—Canham Automobile Co.; capital, $25,000; to deal in automobiles. Incorporator: Roland Canham.

CLEVELAND, O.—Columbian Hardware Co.; capital, $500,000; to manufacture vises, anvils, automobile forgings and a line of hardware goods. Incorporators: Julius Tuteor, H. F. Seymour, A. V. Cannon.

CLEVELAND, O.—Kouyoumajan Electric & Mfg. Co.; capital, $100,000; to manufacture a generator to supply electrical current for automobile lights and for a self-starter. Incorporator: H. K. Kouyoumajan.

COLUMBUS, O.—Babcock Garage Co.; capital, $10,000; to handle automobile supplies of all kinds. Incorporators: Alonzo G. Duer, C. Wagenhausen, L. P. Wagenhausen.

DENISON, TEX.—Davis Livery & Motor Car Co.; capital, $20,000; to maintain a garage. Incorporators: E. E. Davis, Earl Wood, R. I. Aspley.

DETROIT, MICH.—Anguish Mfg. Co.; to engage in the general metal stamping business and to manufacture automobile radiators. Incorporators: J. M. Anguish, C. H. Talbot, F. C. Arthur.

KINGSTON, PA.—Emerick Motor Bus Line; capital, $5,000; to engage in an automobile bus line.

KITTERY, ME.—Tell-Tale Auto Lamp Mfg. Co.; capital, $200,000; to manufacture automobile lamps. Incorporators: S. B. Harvey, Horace Mitchell, M. G. Mitchell.

NEW YORK CITY—Alhambra Auto Painting & Trimming Co.; capital, $1,050; to paint automobiles. Incorporators: Adolph Horenstein, Max Marcus, Herman Marcus.

NEW YORK CITY—Consolidated Auto Supply Co.; capital, $10,000 to deal in automobile supplies. Incorporators: Paul Knopf, Carl Knopf, Morton Bishop.

NEW YORK CITY—Donnelly Motor Equipment Co.; capital, $5,000; to deal in automobile accessories. Incorporators: W. J. Donnelly, Fordyce B. Caswell, R. F. Ely.

NEW YORK CITY—Keaton Patents Co.; capital, $100,000; to deal in rubber tires and pneumatic cushions. Incorporators: Geo. E. Starr, Harold A. Forbes, Chas. M. Merchant.

NEW YORK CITY—Herlihy-Scales Co.; capital, $2,500; to deal in and let sight seeing automobile companies. Incorporators: Dalton Scales, Richard Herlihy, B. A. Judd.

NORFOLK, VA.—Auto Specialty Co., Inc.; capital, $25,000. Incorporators: T. Gray Coburn, F. D. Belote, I. B. Belote.

SPRINGFIELD, ILL.—Auto Owners' Protective Assn.; capital, $2,500; to form an automobile protective association. Incorporators: H. B. Williams, H. B. Conant, R. J. Eutscher.

ST. LOUIS, MO.—Missouri Engine Co.; capital, $35,000; to manufacture coal oil engines. Incorporator: A. E. Winkelmeyer.

WAHPETON, N. D.—Wahpeton Garage Co.; capital, $25,000; to maintain a garage. Incorporators: Frank Eberly, R. M. Lundey.

WICHITA, KAN.—Hockaday Auto Supply Co.; capital, $15,000. Incorporators: F. W. Martin, James Prynne, Cora Hockaday, Ray Hockaday, F. W. Hockaday.

GARAGES AND ACCESSORIES

BIRMINGHAM, ALA.—Turner Bros.; to do a jobbing business in automobile accessories. Incorporators: Oscar C. Turner, John D. Turner, Wm. M. Bowles, J. G. Fitzsimons.

BLOOMINGTON, ILL.—People's Taxicab Co.; capital, $2,000; to maintain and operate a taxicab garage. Incorporators: J. A. Beck, Chester Montgomery, R. A. Jolly.

BROOKLYN, N. Y.—Auto-Transit Co.; capital, $100,000; to maintain automobile and truck livery. Incorporators: J. J. Lilly, J. M. Battle, C. J. Leslie.

BROOKLYN, N. Y.—R-M Auto Repair Co.; capital, $15,000; to repair automobiles. Incorporators: R. D. Marx, W. L. Marx, G. P. Marx.

BUFFALO, N. Y.—Amphibious Garage Co.; capital, $25,000; to maintain a garage. Incorporators: G. F. Staples, T. H. Noonan, H. L. Hommedieu.

CHICAGO, ILL.—Auto Control Co.; capital, $200; to deal in automobile supplies: Incorporators: Lee Hammond, J. B. Lund, A. F. Johnson.

CHICAGO, ILL.—Bartola Keyboard Sales Co.; capital, $50,000; automobile livery. Incorporators: M. M. Franey, A. J. Goldfine, H. P. Munns.

CHICAGO, ILL.—Electric Maintenance Co.; capital, $50,000; to manufacture automobile accessories and deal in supplies. Incorporators: W. B. Christie, C. E. Winters, W. A. Baehr.

CHICAGO, ILL.—Ferns Motor Livery; capital, $50,000; automobile livery. Incorporators: M. M. Franey, A. J. Goldfine, H. P. Munns.

CHICAGO, ILL.—Marshfield Garage; capital, $1,200; to maintain automobile garage. Incorporators: Charles Keller, Henry Hantover, Maurice Klein.

CHICAGO, ILL.—Modern Auto Starter Co.; capital, $10,000; to manufacture automobile accessories. Incorporators: M. I. Rosenbaum, M. Richardson, Maurice Altschuler.

CHICAGO, ILL.—Modern Garage & Motor Livery Co.; capital, $2,500; to maintain an automobile livery and garage. Incorporators: P. P. Harris, R. W. Warner, John Pfeiffer.

CINCINNATI, O.—K. Auto Delivery Co.; capital, $10,000; to do automobile trucking. Incorporators: Edward Konker, Geo. W. Bell, Anna Konker, Gus Konker, Fred Schmidt.

CHANGES OF NAME AND CAPITAL

AKRON, O.—B. F. Goodrich Co.; capital decreased from $200,000 to $10,000.

CHICAGO, ILL.—Krickworth Motor Wagon Co.; change of name to Mahaska Hotel Co.

CINCINNATI, O.—Queen City Delivery Co.; capital, $50,000.

CLEVELAND, O.—City Auto Tire & Repair Co.; change of name to City Auto Tire & Supply Co.

DES MOINES, IA.—Riddell Automobile Co.; change of name to Clemens Automobile Co.

FORT WORTH, TEX.—Allen-Vernon Motor Car Co.; change of name to Harrison-Vernon Motor Car Co.

FOSTORIA, O.—Allen Motor Co.; capital, increased to $500,000.

GULL LAKE, SASK.—Burgess Patent Tire Co. of Canada; capital, $600,000.

PADUCAH, TEX.—Mayer, Street & Alexander; change of name to Street-Whittington Co.

ROSSLYN, VA.—District Automobile Service Co.; change of name to G. R. Cowie Co.

SYRACUSE, N. Y.—Syracuse Auto Radiator Co.; capital, $50,000; to manufacture and deal in auto radiators. Incorporators: M. Kaman, T. Vickers.

Export Field for American Cars Grows

THE calendar year 1912 has brought out several surprises in the manufacturing world, especially in the automobile field. In former years the American car was a very small factor in the trade of foreign countries, but with the advent of the cheap car costing around $1,000, the United States has forged to the front and now ranks with the other nations in this field. Our manufacturers are establishing stations in South America and other parts of the world where the owners there will be convenienced with ready parts and service.

Low-priced Automobiles—An American consular officer reports that a firm in his district desires to be placed in communication with American automobile manufacturers, with the intention of importing cars which cost $1,000 or less delivered, duty paid. This firm desires prices c.i.f., city of destination, and states its willingness to undertake the agency or representation of a firm manufacturing a low-priced automobile, being of the opinion that there is a good opportunity for the sale of same if properly introduced. Catalogues, discounts, prices, conditions, etc., are requested. Clear understanding as to granting or representation as agent is also requested by the firm. Correspondence should be in Italian, French or Spanish. Inquiries at the Bureau of Foreign and Domestic Commerce, Washington, D. C. File No. 10851.

Heavy Oil Motors—A report from American consul in a European country states that a local business man desires to communicate with American manufacturers of heavy oil motors. Quotation, etc., should be addressed direct to the inquirer. File No. 10901.

Automobile and Agency—The secretary of an automobile club in a European capital informs an American consular officer that he wishes to buy an automobile for his own use from some company he might represent as agent. The price of the automobile should not exceed $1,300, and the car must be a good hill climber. Correspondence may be in English. File No. 10930.

Electric-motor Ambulances—An American consul reports that the medical officer of a local municipality has left for London on leave of absence, and he has been instructed by the council to examine the different makes of electric-motor ambulances with a view to the purchase of two such vehicles for local use. One of the ambulances is intended for ordinary use and the other is for handling infectious-disease cases. American dealers in electric vehicles who may be interested should send catalogues, price lists, etc., to the London address of this officer, or have their representative call on him. All correspondence regarding the ambulances should be in English. File No. 10984.

Electric-motor Trucks—A foreign municipal engineer is now testing an American electric-motor truck imported by a local firm, in handling city refuse. An American consul reports that the test will last about a month, and if it proves successful the engineer will recommend the purchase of half a dozen trucks of different makes to compare the efficiency of each, after which it is possible that about twenty-five of the make decided upon as the best for the local needs will be purchased. American manufacturers of electric-motor trucks who care to compete in supplying these trucks should send descriptive catalogues to the engineer at the earliest opportunity, and should quote him their lowest possible prices. Correspondence should be in English. File No. 10987.

Motor Cars—A report from an American consul states that a large shipping and agency firm, with branches in several cities, desires to get into touch with American manufacturers of low-priced American motor cars with a view to becoming the agents for such firms. All correspondence on the subject should be in English and should be addressed to the head of the firm whose name is furnished. File No. 10934.

Motor Agency.—An importer and general merchant in an African city informs an American consular officer that he desires to negotiate with manufacturers of motors for the exclusive agency for a certain territory. He is especially interested in the Porto motor, which is said to be an American engine, and he believes that on account of its small dimensions he can handle it successfully on the local market. It is requested that duplicated catalogues, etc., be sent to the consular officer for reference in case the inquirer does not take up the agency. File No. 10937.

Motor Fire Engine—The American consul at Leeds, England, reports that the town council of Pudsey, Yorkshire, England, has appointed a committee to investigate conditions of fire protection. A motor fire engine is among the equipment the committee expects to procure. Correspondence should be addressed to the town clerk, Pudsey, Yorkshire, England, for use of the special committee referred to. File No. 10974.

Gas Motors and Automobiles—A report from an American consular officer in the near East states that a member of a very prominent family in his district, and one of the leaders in the country, desires an agency for gas motors, 2 to 6 horsepower, motor, 16 to 45 horsepower, and an 8-horsepower four-seat automobile specially adapted to hill climbing and one 8-horsepower gas motor for an oil press. Prices should be quoted c.i.f., city of destination, delivery not later than August. File No. 10708.

German Automobile Developments—German automobile manufacturers report that 1912 was an entirely favorable year for them. It brought an expansion surpassing even in percentage that of 1911. According to official provisional statistics now available, the foreign trade grew from $14,268,000 to $21,347,000 in the course of the year, and reports of the home trade, although not yet in statistical form, indicate as favorable a situation. The greater part of the growth in foreign trade is accounted for by increased exportation, especially of passenger automobiles. In 1911 Germany exported 5,154 vehicles of this type, worth $10,099,000, in 1912, 7,948, worth $15,473,000. Motor trucks were exported in 1912 to the number of 694, valued at $1,849,000, as compared with 346 in 1911, valued at $980,000. Germany's imports of automobiles did not increase in the same proportion as her exports. In value they grew from $2,792,000 in 1911 to $3,432,000 in 1912, an increase of only 22 per cent., as compared with 56 per cent. in the case of exports. In number the increase was from 1,823 to 2,267. Germany's importation of motor trucks increased from 134 to 201 in number and from $390,000 to $607,000 in value. The aggregate value of the vehicles produced in 1911, including extra parts and the value of repair work done during the year, is given at $37,300,000, as compared with $26,000,000 in 1910 and $17,300,000 in 1909. The aggregate value of the products of auxiliary and dependent industries in 1911 is estimated at $48,500,000.

American Trade with London—The total import value from London to the United States during 1911 and 1912 was $458,829 and $392,054 respectively. Special attention is called to the importing of American cars into London, from the United States, in 1911 of the aggregate value of $2,253,321, while in 1912 the value rose to $2,867,993. The average price of the American automobile imported in 1912 was $972, as against $762 in the preceding year, showing a growing demand for the higher-priced automobile of American manufacture.

Italy Sells 3,587 Automobiles—Automobiles sold abroad by Italy last year numbered 3,587, having an average value of nearly $2,000. Exports in 1911 and 1910 numbered 2,918 and 2,120, respectively.

Birmingham's Exports to U. S.—The declared exports from the Birmingham district to the United States and possessions, in 1911 and 1912 were $131,642 and $160,075 respectively.

American Trade in Rangoon—During 1912, forty-one automobiles, valued at $32,246, were imported from the United States, as compared with fifteen cars, valued at $12,063, in 1911. During 1912, 120 artomobiles were registered in Burma, of which forty-eight were American.

American Trade in Switzerland—The invasion of Europe by the American-made automobile, which until a few years ago was denounced by the continental manufacturers as cheap and worthless, continues. The demand for American cars in the Swiss market is confined generally to those of medium or low price, as the European manufacturers have given little attention to the production of that class of machines. The American automobile has taken its place beside the best makes of other countries, its efficiency and durability having been demonstrated by the severest competitive tests of speed and endurance. About fifty American automobiles were sold in Switzerland within the past year, and agencies have been established in several places in the Confederation for the exclusive sale of the medium-priced motors of American make.

Accessories for the Automobilist

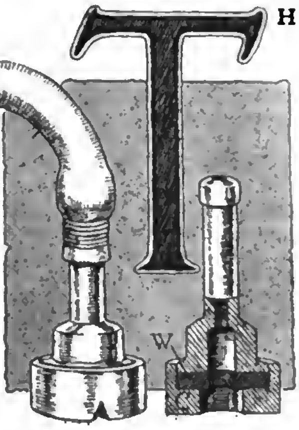

Fig. 1—Carrs B & G connection

THE Crouse Starter—The Crouse Air Crank, made by the Auto Air Appliance Co., Annapolis, Md., is constructed on the compressed air principle and utilizes a rack-and-pinion mechanism for cranking the motor. It consists of a cylindrical casing C, Fig 3, part of which is formed as an air motor cylinder in which a piston P, packed against the wall, is reciprocable, although ordinarily it is pressed against one cylinder end by a spring S. If air is admitted from that end through a pipe A, the piston is moved against the spring pressure and presses the connecting rod Q outwardly. Q is linked to the rack R meshing with a pinion C mounted at the front of the crankshaft. Consequently, the movement of the piston cranks the motor. The rack is in engagement with the pinion only when air enters through A, as then not only piston P is actuated, but some of it passes through the passageway O bored in Q into two small cylinders D containing springs T. The later press against pistons to which the rack is connected, thereby forcing the latter away from the pinion. When the end of the stroke of P is reached, the admission of air ceases automatically, the springs T retract the rack and S returns the P, Q and R to their original position, ready to be moved again if the motor has failed to start.

Johns-Manville Extinguisher—The H. W. Johns-Manville Co., New York City, manufactures a new fire extinguisher which comes in bombs, being composed of a compressed, incombustible gas which is five times heavier than air. One quart of this gas if released develops 4,000 cubic feet of gas at atmospheric pressure, being sufficient to quench any fire at the time of starting. The gas is dry, and as it contains no moisture, it produces no rust nor corrodes metal parts if applied to them. Likewise, it does not injure the skin, fabrics, etc.

Tribune Double Headlights—A novel and exclusive feature of the new Tribune Thirty-Six is a double electric headlight, Fig. 2, combining the functions of sidelight and headlight by means of two bulbs in each. The larger bulb, of 16 candlepower, is located conventionally in the apex of the reflector, while the smaller bulb, of 6 candlepower, is just beneath. It is claimed for this arrangement that greater efficiency is obtained, especially for the smaller lights. The current for the lights is supplied from a storage battery, charged by a lighting generator.

Weed-Chain Plier—The Currier-Koeth Mfg. Co., Coudersport, Pa., make, among other automobile tools, a plier for the adjustment of Weed chain links. The pliers are made of steel and the jaws are so formed as to easily open the link to just the right distance. The tool may be operated with one hand.

Carrs Special Tire Hose Connection.—C. Carrs, of 1777 Broadway, New York City, has begun the manufacture of special connections for tire inflation hose, Fig. 1. This connection, as it is called, simply consists of a specially formed lock which fits in place of the ordinary lock of Acorn and Eclair connections used to produce a sliding joint between the inflation hose and the valve stem. In the case of Acorn and Eclair connections, a rubber washer is in place between the cup and the cap, and the end of the hose, fitted with a metal piece, is shoved into the rubber washer, which keeps the air from escaping. However, when the tire is pumped up to a pressure considerably below that demanded by the maker, the hose frequently blows off, especially when the rubber washer has been used for some time. In order to prevent this in the case of the B & G connection, Fig. 1, the same which forms a cap is threaded to fit over the cup of the ordinary connections replacing the common caps, and the inner surface of the cap is threaded along a thin longitudinal zone, so as to be capable of engagement with the thread formed on the tire valve casing. The latter, as is well known, has two flat surfaces, where the thread is cut away. In puting the connection on the tire valve, the end of the valve casing is pushed into the opening of the cap C, in such a position that the threaded portion of the cap, marked outside by a cut-away in the metal, comes over the unthreaded portion of the valve casing. When the end of the latter has been driven into the rubber washer, the connection is turned, and the narrow thread in the cap engages that on the valve casing, thereby locking cap and casing against relative longitudinal displacement, movement along screw lines given by the casing thread being the only possi-

ble. Now, of course, the reaction of the air entering through the valve is not strong enough to displace the connection, and, whether the washer is new or old, the connection cannot blow off.

Dean Electric Fordorn—The Dean Auto Devices Co., Chicago, is the maker of the Fordorn automobile signal, which is electrically operated, using the excess current generated by the powerful magneto of the Ford car. The horn consists of a brass trumpet, which is attached to a black-enameled frame. The latter is fastened by screws to a heavy steel ring supporting the motor magneto and the armature which is vibrated by the motor-driven ratchet. The motor magnet is composed of thin iron plates varnished to insulate them of one another. A diagram showing how the horn is to be connected with the ignition circuit is furnished with the device, and control is by means of a button, which is preferably mounted on the steering wheel of the car.

Townsan Leaf Spring Spreader—In Fig. 7 the Townsan spring spreader, made by the Townsan Auto Specialty Co., Mitchell, S. D., is illustrated. It consists of a steel bar shaped as a channel to embrace the spring across its width. A steel wedge is secured to one end of the channel, while the other is formed with a threaded hole through which screws a bolt carrying a conical steel point at its end. By placing the wedge between two leaves on one side of the spring and the point on the other side, and by then working the screw carrying the latter, the two leaves are spread apart and a possibility is afforded to put lubricant between them.

Bryant Service Lock—Fig. 4 shows the Bryant automobile lock which consists of a vertical bar formed as a rack and secured to the gearshift lever so as to not be removable therefrom, and a part slidable upon the same but ordinarily engaging the rack. Engagement and disengagement of the slidable part and the rack are controlled by a Yale lock; so that, unless the tumblers are turned by means of the individual Yale key, the relative position of rack and part cannot be changed. The slidable part carries at its lower end a fork taking up the space between the gearshift lever and the quadrant if the part is lowered when the gears are in neutral. Attachment of the device to the lever is so that it cannot be taken off the same.

Westhaven Patent Plier Wrench—The West Haven Mfg. Co., New Haven, Conn., is the maker of the plier wrench, Fig. 6, which is constructed with an adjustable jaw movable by means of a setscrew. In using the plier as a wrench, the setscrew takes the strain which otherwise would be transmitted by the jaw to the pivot, in other words, half of the working strain. The jaw, which is operated by the setscrew, is formed with serrations along its gripping face, and the plier is therefore made available to act as a wrench in grasping round objects. The second jaw is formed with a slot across which cuts the knife edge of the lever supporting the first jaw, thus making it possible to use the tool as a wire cutter.

Herz Tape Grip Rings—Herz & Co., New York City, have brought out a new device for coupling rubber tubing on to metal pipes, especially for water conduits around the engine. The device, Fig. 8, consists of a metal ring formed along the inside of one edge with an inward rim. A slot is cut through the ring, and the operation is as follows: To obtain a tight connection between rubber hose and the pipe, the end of the hose is slipped over the latter and the ring is then put on top over both. It now remains to take up the slack between the two and to do this white tape or black tailor's tape is slipped through the slot in the ring; then the latter is begun to be turned. As it turns, the friction between the rubber and the tape keeps the latter in close adhesion to the former, and as a result tape is wound up around the rubber hose and inside the ring. The more tape is thus used, the tighter becomes the joint. If enough tape is used, the joint becomes not only waterproof, but gastight as well.

Gurney Solid Ball Retainer—The Gurney Ball Bearing Co., of Jamestown, N. Y., has designed the new retainer, Fig. 5, which is now being used in its ball bearings. The retainer is made of a single piece of anti-friction metal shaped as a ring and formed with a number of cavities for holding the balls of the bearing. These cavities are so dimensioned as to easily accommodate the balls, yet at the same time avoid all lost motion. Thus, they are permitted to rotate freely in the retainer, and due to the composition of the latter—from anti-friction metal—there is very little resistance to the free movement of the balls; incidentally, the chemical constituency of the metal which makes it frictionless, also prevents the generation of noise between balls and retainer, so that the bearing is very quiet. The remainder of the Gurney bearing, not shown here, are chrome steel rings and balls, which are maximum with respect of the circumference.

Woodworth Inner Tire Sleeve—A new inner sleeve or liner, Fig. 9, is being made by the Woodworth Tire Good Co., Niagara Falls, N. Y. It is made of heavy chrome leather and is lined with five buttons and holes into which these fit, a flap overlapping the button line so as to reinforce the inner circumference of the inner tube. If it is desired to apply the liner for the purpose of reinforcing the tube in a weak place. the tube is removed from out the shoe and after being inflated to the correct degree is surrounded by the liner, after which it is replaced in the casing. Each sleeve is made with two rows of buttonholes, making it usable for two tire sizes.

This is the factory that produces

The Noiseless North East Electric Starting And Lighting System

It is the finest and best equipped plant in the world devoted exclusively to the production of electric systems for the starting and lighting of Automobiles.

For four years we have been building electric starting and lighting systems—not so much, however, with the idea of producing in large quantities at the start, but more with the aim of turning out the highest possible quality.

We have been concentrating our efforts and our energies upon the development of our plant and of our organization, and upon the improvement of our machine.

As a result of this highly developed organization and splendid equipment, the North East Electric System—a simple single motor-generator of our own creation and construction throughout—is the lightest, most compact, most flexible, most powerful and most economical electric system ever put together.

It turns the motor noiselessly, at exactly the right speed under all conditions, with a minimum of wear and tear on the battery.

The North East Electric System is now standard equipment on many of the best cars. Give us the opportunity, and we can demonstrate that the North East is the system you want on your new car.

"COMPLICATED STARTERS WON'T DO"

That's what automobile **owners** and automobile **dealers** are saying.

They agree that the Electric Starter has come to stay, but all will be careful to avoid **complicated** starters that puzzle the brain of any garage man that attempts an overhauling.

Thus comes the **increased** popularity of the **Electric** Disco, which is **NOT** a complicated starter.

Motor car makers are paying more for this starter than for any other, **to avoid mechanical complication. They want their cars to be trouble-proof** as well as efficient.

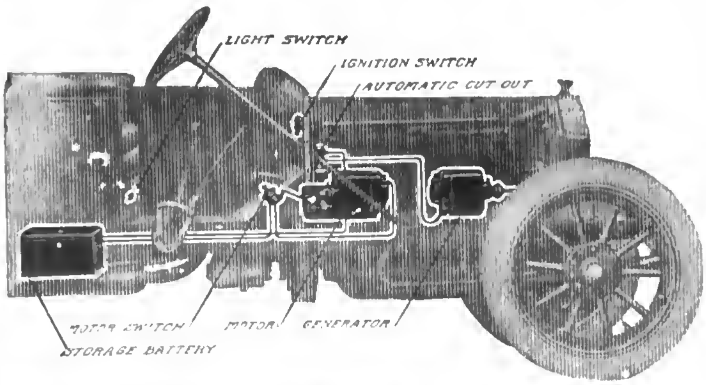
You, Mr. Motorist, should heed these facts. Then you'll get the benefit of a **simplified** electric starter.

Spinning or Cranking?

In comparing Electric Starters, the experienced motorist also notes the **speed** at which the motor revolves.

The difference is very noticeable.

The average electric starter gives a speed of 40 to 50 revolutions per minute. It cranks, but does not **spin** the motor.



The **Electric Disco,** at the touch of the button, spins the engine 150 revolutions per minute.

Think what this additional speed means on a cold day when the engine is dead and the oil stiff.

It means not only a **sure** start but an **instantaneous** start.

Leading 1914 Cars Carry Disco Equipment

More automobile manufacturers are being added right along to the list of Disco users. And the greatest engineers in the country concede that the **Electric Disco** is built of the best materials and in the most expert manner. That's because we are not jobbers. We make our own parts, thus attaining a precision otherwise impossible.

Before You Buy

your car, look into this starter subject carefully. Sooner or later you must know starters. And the time to know is **before,** not **after** your car is delivered. **FOR YOU CAN'T CHANGE STARTERS. THE STARTER** is built into the car.

Send for the Electric Disco Book. We have equipped over 150,000 cars. Surely our experience should be worth something to you. A postal sent today brings answer by return mail.

Portable Garage Is a Problem Solver

Private Housing of the Automobile Makes for Economy and Convenience—Garages that Can Be Easily Erected by the Owner

By Sydney Oxberry

WHAT owner making use of the public garage as a storing place for his car has not often allowed his mind to run on the desirability of having his machine transferred to a more convenient place at his own door, where it is ready at a moment's notice, where he is sure no careless outsider is tampering with its mechanism, or joy riding, or appropriating expensive gasoline? A private garage next his own house allows the motorist to proudly display the particular mechanical wonders of his latest speed wagon to every visitor. When a run is suggested there is no long walk to the public garage and no telephoning and the aggravating delay; the car is right at hand. And after a long run with a house party what a much more satisfactory conclusion it is to drive triumphantly up to your own place and deposit your passengers without further trouble.

Nobody would dispute these advantages, but the chary motorist still hesitates to adopt the private garage, sometimes because of the cost, and often because he cannot be sure of the permanence of his residence in one locality, and the expense of erecting a new building for the car at each removal hangs ominously over his mind.

The anxiety is largely without foundation. For the comparatively small outlay of about $200 he can have a firepoof garage with some pretention to good appearance delivered at his home in a few days and erected—by himself if he is at all handy—in a further couple of days, that will house his car and pay for itself in saved storage charges in a few months. The portable garage, as this convenient solution of the housing problem of the automobile is named, is represented by an industry that is already of considerable size, over thirty concerns, furnishing all sizes and types from all-wood, wood and canvas, wood and steel, and all-steel constructions being in active operation. A great variety of styles to suit all tastes are available. The most popular is a plain gable-roofed structure with a floor plan of 12 feet by 18 or 20 feet, provided with an 8-foot door at one end. Many of these are supplied in interchangeable wall sections 2 or 3 feet wide, and are simply bolted together on a framework that is also easily demountable. By these means an erection of any desired length in 2 or 3-foot stages is obtainable. It is the custom of practically all makers to furnish window sections identical in size with the plain side units, so that the number and placing of the windows are at the discretion of the erector.

Fig. 1—View of a typical one-car fireproof portable garage that can be erected without special foundation in a couple of days. Fig. 2—The same en route for new quarters

The size of garage required should receive careful consideration by the prospective purchaser. It is true that a shed 10 feet by 14 feet will accommodate a small runabout, for instance, but to be of really practical use it is advisable to

Fig. 3—Fireproof Rusk garage of gable type with ornamental pressed steel sides and hinged window

Fig. 4—Combined workshop and garage by the Metal Shelter Co. The equipment includes a forge with chimney, as shown

choose always on the roomy side. For one thing it is not at all unlikely that the owner of such a machine may be the possessor of a touring car long before the garage has outlived its usefulness. Secondly, and this is of greater importance, nothing detracts more readily from the philosophic calm with which one approaches a repair job than to be cramped for space. Therefore, see that not less than a 3-foot passage way all around the car is provided for. Wheel repairs, in particular are thereby rendered much easier of execution.

Workbench Is Important Accessory

Another matter affecting the size of the garage chosen is the ever useful workbench that ought always to form part of the equipment of every garage, however small. The many repairs that can be easily accomplished with the aid of a small workbench and vise will surprise the automobilist who has been long accustomed to rely on professional aid at every minor ailment of his car. The handiest location for such a bench is at the end opposite the door where, needless to say, there should be a window for daylight work.

Of the two principal constructional methods, wood and sheet steel, each has its advantages and disadvantages. Wood is of course the cheaper, but it does not lend itself so readily to frequent dismantling, nor is it fireproof, both of which points are the principal recommendations of the all-metal garage, though the latter has a somewhat higher initial cost.

As at present designed neither can claim a superiority in the matter of ease of erection. With the help of a friendly neighbor, a stepladder, square and wrench almost any portable garage can be erected in a couple of days.

It may be as well to point out here that the term portable in connection with garages has a wide meaning. All the steel constructions are portable in the full sense of the term, as well as many of the sectional wood type, that is, they can be put together and taken down an unlimited number of times without any detrimental effect on the parts. But the term is stretched to include those wooden constructions which are supplied in accurately cut pieces of lumber capable of being erected without a permanent foundation. These latter are not really at a very serious disadvantage for the owner who lives any length of time in one place. It is not advisable to take such a garage to pieces for re-erection, though that can be done, and any rate in the case of the smaller models it is an easy matter to lift the entire structure onto a wagon for transportation.

Before deciding on a particular garage the building laws of the locality relative to danger from fire should be carefully looked over, and the size of the available plot with reference to distance from adjacent dwelling houses considered.

With regard to the fixing of the garage on the ground, for the smaller types a common and quite satisfactory method is to drive creosoted wood stakes into the ground at the corners and sides, on which the frame uprights or the horizontal sill extending along the lower edge of the walls are bolted. Another favorite foundation suitable for a more or less permanent erection is a set of cement piers with a foundation bolt imbedded in each to which the sill is anchored.

So much diversity of opinion exists as to what is the most desirable method of flooring that the manufacturers of portable garages prefer to leave that detail to the individual taste and requirements of the purchaser. Much, of course,

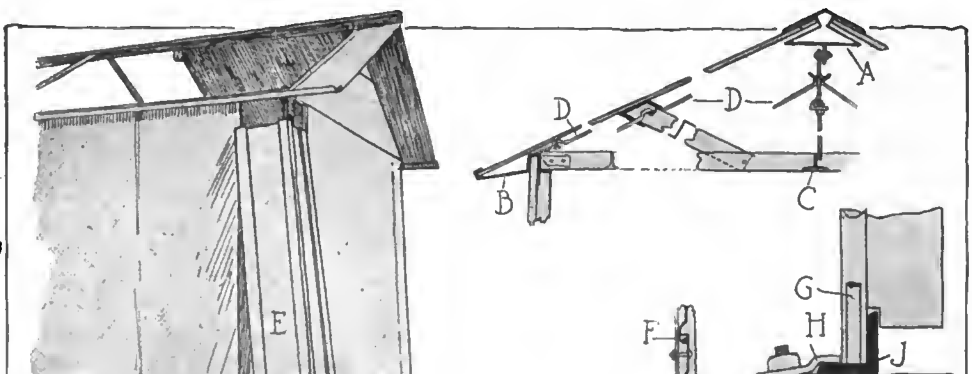

Fig. 5—Fitting of corner and other details of Pruden construction

depends on the nature of the ground, whether it is intended to wash the car inside, drainage facilities available, etc. A cement floor offers perhaps the most advantages, but the trouble and expense of laying one can be avoided by adopting the simple substitution of a couple of wide runboards with a cinder filling. If the soil underneath is at all absorbent this style of floor will be found to allow water to soak easily through the cinders when washing.

Another flooring recommended is a load or two of cinders mixed with cement as a binder. This floor is fireproof, but a means of drainage must be provided or the car always washed out of doors.

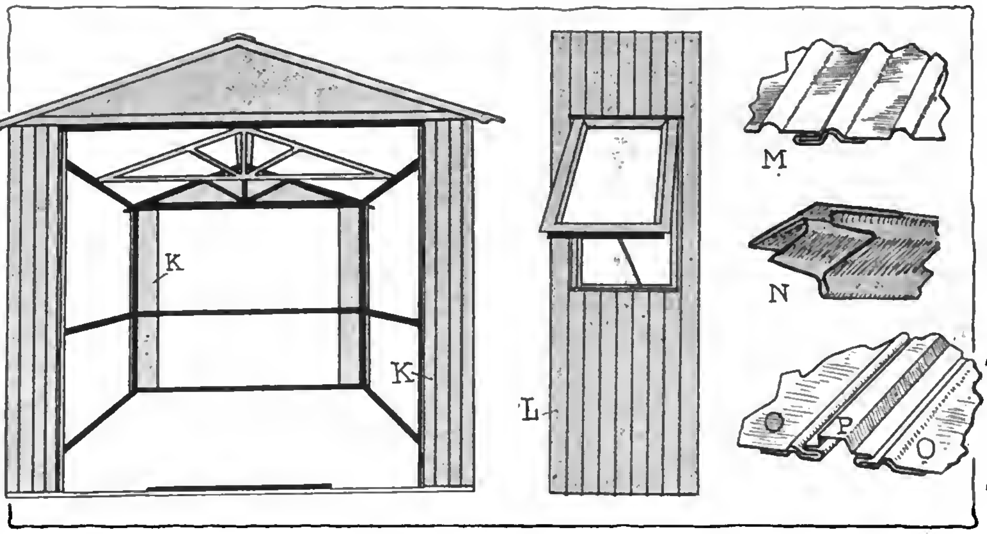

Fig. 6—Framework, side unit and joints in Edwards' portable construction

The constructional features by which the sections of the various portable garages are coupled together to form a watertight joint display much ingenuity. In one metal design the wall units are provided with strengthening webs permanently attached to the inner face, while others receive the required rigidity from the special form of the connecting bar which joins the adjacent sections. A great degree of rigidity is also imparted to the metal sheet either by stamping in ornamental patterns or the more usual corrugations. A popular type of metal siding is that pressed to resemble weatherboards. It is strong and simple and does not offer the same risk of incongruity of appearance with the residence that is the case with the more ornate patterns, though many of the latter regarded alone are pleasing in effect.

In the matter of general appearance a large range of choice exists. The hip roof, an example of which is shown in Fig. 10, always gives a good impression. This style of roof, however, requires a more complicated frame and does not lend itself to the portable feature so well as the ordinary gable roof. The rectangular sides of the gable type of roof facilitate their division into sections in a similar manner to the walls.

The garages shown in Figs. 1 and 4 are two of the many types constructed by The Metal Shelter Co., St. Paul, Minn., which makes structures of any width from 8 feet to 20 feet by any length. The principle of construction is a system of interlocking units in sheet metal, each complete in itself, containing all framework, which when attached to other units completes the structure.

The method of construction is shown in Fig. 5. All the side units measure 2 feet in width by 8 feet high and are made in 24-gauge galvanized steel. Both long sides of each section are formed into tubes or beads in such a way that one section can be rigidly attached to the adjacent section by simply passing a steel rod .375 inch diameter through the junction from top to bottom. At the base these rods pass through and are bolted to a steel angle which forms the sill on which the entire garage rests. This sill is shown in the detail sketch at J, which also illustrates one method of fixing to a cement pier foundation by means of clips H. The vertical connecting bolt is shown at G. After fitting the sides together they are raised to a vertical position and the corner pieces E added. These are bolted to the adjacent side units, the corner itself being supported by one of the vertical rods already referred to.

The windows are 4 feet by 2 feet and are located 4 feet from the ground. They are glazed with .25-inch wire glass or clear glass.

Truss Construction for Roof

Galvanized steel is used for the roof, the sheets resting at their lower edges in special eaves B, Fig. 5. The upper edges meet in a metal ridge A and the whole roof structure is made firm by tightening up the tie rods D. A longitudinal T-iron C extends the entire length of the building to which the cross and oblique members are attached, forming a trussed system.

Prices for the standard one-car garage from $176 for the 10

Fig. 7—Pinyoun wood house with single slope roof. Ample light is afforded by glazed doors and side windows

Fig. 8—Kenyon handy portable of waterproof canvas stretched over wood frame that can be erected in a few hours

Fig. 9—Handsome two-car house with hip roof by Springfield Co.

by 12 feet size, upwards, the 12 by 18 feet being listed at $251. Two-car garages by the same concern and on the same principles cost from $322 for the 16 by 16 feet size to $483 for the largest, measuring 24 feet long by 20 feet wide.

A typical one-car "Pruden" garage is shown in Fig. 1. Fig. 4 shows a special construction in which a workshop is combined with the garage proper. This particular model, measuring 18 by 20 feet, is listed at $403. The equipment includes a steel locker for tools, a steel framework for a workbench, and a 5-foot chimney for forge.

The Edwards Mfg. Co., of Cincinnati, O., has evolved a simple system of unit construction fireproof garages that make up into structures with a distinctive appearance. These are made in two types, the "Steelcote," of galvanized steel sheets mounted on a wood frame, and the "All-steel" type, having a framing of angle-iron and being absolutely fireproof.

The framework throughout is angle-iron 1.25 inch by 1.25 inch, and this is supplied ready drilled for the attachment of the side sections. The sills, that is, the lower angles which rest on the floor, are connected at the four corners by angle plates which brace the structure and insure its perfect rectangular form. The method of erection will be clear by reference to Fig. 6 which shows at the left the building partially raised. It will be noticed that additional strength is given to the walls by the use of a central horizontal angle-steel extending around the sides and back at a height corresponding with the lower edge of the windows. Once the frame is erected the corner pieces K are applied and bolted to the corner pillars.

A particularly ingenious method of connecting the sections so as to form what is practically an air-tight joint is used. This is shown in detail in the same illustration. The edges of the adjacent sections O O are held near together and the connecting strip P inserted between them. The piece P extends from sill to roof and its strong channel section will be noted as well as the method of obtaining a sealed joint by means of the vertical flutings in all three parts. In the roof a similar method of fluted water-tight joint M is utilized. At N is shown a section of the roof ridge also made in galvanized steel.

The doors are each 4 feet wide by 8 feet high, formed from 1.25 by 1.25 inch angle steel, braced at the corners and covered with beaded surfacing as used for the side units. The windows. 27 by 36 inches, are swung on hinges at the top, as shown at L in Fig. 6.

For the roof this concern supplies plain sheets or a special pressed steel imitation of Spanish tiling which is attached with concealed nails. Twelve standard sizes are listed, ranging from 10 feet wide by 14 feet long to 14 feet by 20 feet. The prices are from $92.50 to $127.50 for the "Steelcote" type and from $150 to $200 for the all-steel type. The 12 by 20 feet all-steel garage costs $180 and weighs 1900 pounds.

Reduce Number of Parts

Among the makes of all-metal garages in sections, those by the Anchor Corrugating Co., New York, are unique in that the number of parts is reduced to less than half that usually employed. By this means a much simpler construction is obtained, having fewer joints. Contrary to what might be supposed, no part is unwieldy, the heaviest section weighing 50 pounds. A 12 by 18 foot structure by this concern costs $253.

Fig. 3 shows a Rusk fireproof garage with a floor plan of 12 feet by 18 feet. The construction of these buildings is very simple. A rectangular framework of galvanized angle-iron is erected and on this the side walls are bolted. The same concern also manufactures similar structures with wood frames at a lighter cost. The prices range from $101.50 to $235. The example shown in Fig. 3 costs $175 in all-metal and $136.50 in the wood frame type. The makers are The Fargo Cornice Co., Fargo, N. D.

The garage shown in Fig. 7 is a neat wooden building that

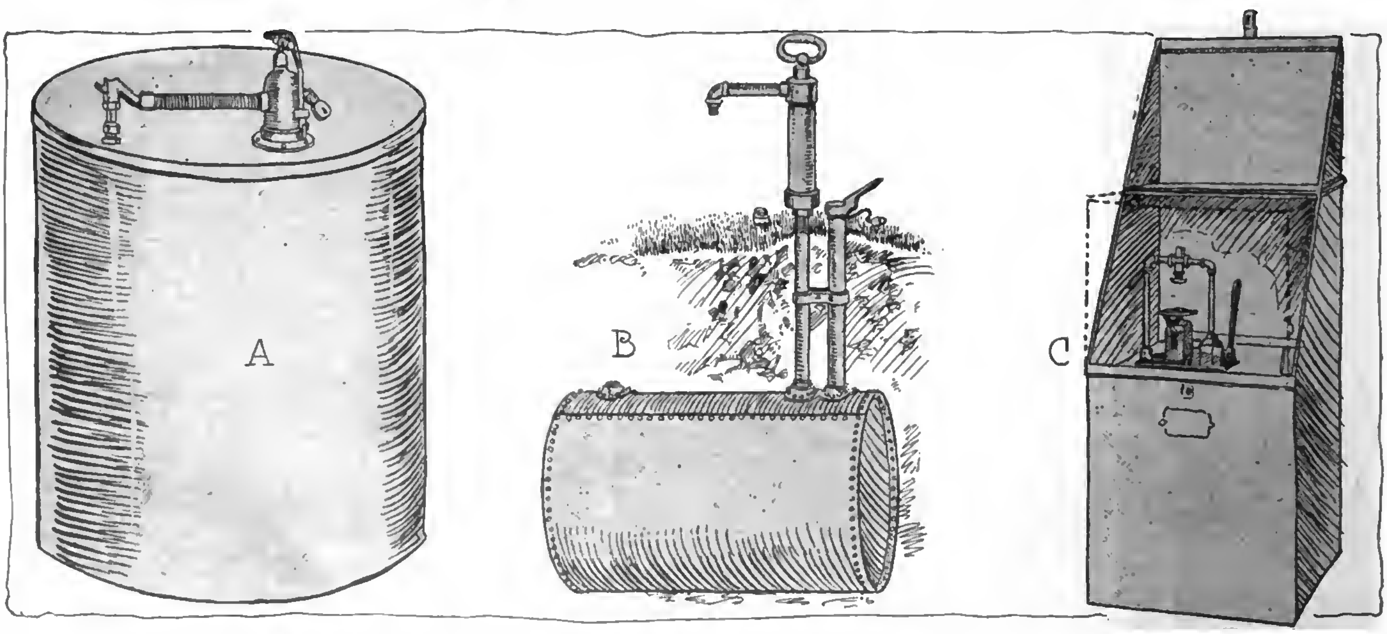

Fig. 10—A, portable gasoline tank with locked pump. B, underground tank for gasoline. C, portable container for oil

can be erected with the help of a wrench and screwdriver. No foundation is necessary, the whole structure being mounted complete on a wood sill at the base. It will be noticed that ample provision for light is made. These garages are made by Pinyoun & Son, Cleveland.

Wood Buildings Look Well

Other wooden buildings of good appearance are shown in Figs. 9 and 11. Fig. 11 is an Aladdin garage by the North American Construction Co., Bay City, Mich. It measures 12 by 20 feet and sells at a net price of $165.30. The other is the product of the Springfield Co., Springfield, Mass. The striking appearance obtained by the hip roof with a slight pagoda dip will be observed. This two-car garage measures 18 by 20 feet and costs $450.

The garage shown in Fig. 8 is an extremely simple affair in canvas and wood. It looks well, can be erected in a few hours, having only slip in joints and thumb screws, and affords ample protection from the weather. It is manufactured by the Kenyoun Co., Waukesha, Wis. The price of a 10 by 16-foot house of this type is $84 without a floor, and the weight only 475 pounds.

A complete list of manufacturers of portable garages follows:

American Portable House Co., Arcade Bldg., Seattle, Wash.
Anchor Corrugating Construction Co., 62 Cortlandt St., N. Y. C.
Berger Mfg. Co., Canton Ohio.
Burnham-Standeford Co., Washington & First Sts., Oakland, Cal.
Chesbro-Whitman Co., 1167 First Ave., New York City.
Craig, David, 70 Broad St., Boston, Mass.
Ducker Co., 277 Broadway, New York City.
Duluth Corrugating & Roofing Co., Duluth, Minn.
Edwards Mfg. Co., 724 Eggleston Ave., Cincinnati, O.
Gordon Mfg. Co., Middletown, Ohio.
O. K. Harry Steel Co., 2333 Papin St., St. Louis, Mo.
E. F. Hodgson Co., 116 Washington St., Boston, Mass.
Ideal Sectional Bldg. Co., St. Johns, Mich.
Illinois Portable House Co., 6331 Evanston Ave., Chicago, Ill.
Karr Portable House Co., 2554 W. Irving Park Blvd., Chicago. Ill.
R. L. Kenyon Co., Waukesha, Wis.
Knapp Portable Permanent Bldg. Co., 111 Broadway, N. Y. C.
Mershon & Morley Co., Saginaw, Mich.
Metal Shelter Co., 3 West Water St., St. Paul, Minn.
New York Portable Bungalow Co., Poughkeepsie, N. Y.
Niles Iron & Steel Roofing Co., Niles, Ohio.
North American Construction Co., Bay City, Mich.
F. C. Pinyoun & Son, 2526 Carnegie Ave., Cleveland, O.
Portable Construction Co., 50 Church St., New York City.
Riverside Mfg. Co., 162 Riverside Ave., Newark, N. J.
J. S. Rogers Co., Moorestown, N. J.
Ruby Mfg. Co., Jackson, Mich.
St. Johns Portable Bldg. Co., 30 Church St., New York City.
Springfield Mfg. Co., 801 Allen St., Springfield, Mass.
Wyckoff Lumber & Mfg. Co., Ithaca, N. Y.

As regards equipment for the garage the safe storage of gasoline is a matter of prime importance.

If the motorist is using a portable garage and does not wish to go to the trouble involved in the sunk tank, a strong cylindrical tank fitted with a pump and strong pipe connection should be obtained and kept out of doors. It should be remembered that insurance difficulties are much more in evidence when gasoline is kept inside the garage.

Fig. 11—Neat Aladdin garage in wood with glazed doors

A gasoline tank that is suitable for the purpose under consideration is shown at A, Fig. 10. This particular tank is supplied in three sizes, containing 65, 110 and 160 gallons.

An underground tank is shown at B. The pump is screwed into the ground pipe and after using can be removed and a special locked cap put in its place.

A handy container for lubricating oil that is portable and convenient is depicted at C, Fig. 10. All three tanks in this illustration are by S. F. Bowser & Co., Fort Wayne, Ind.

Other types of storage tanks are shown in Fig. 12. The outfit B is supplied by the Cleveland Faucet Co. in two sizes. The 66-gallon tank is listed at $21 and the larger size, taking 120 gallons, at $37.50. These tanks are made of heavy steel with welded seams. The pump A is provided with a foot for mounting inside the garage. At B the pump is shown attached to the tank.

The tank shown at C is intended to be located outside the wall of the garage, as shown. Fitted complete, this outfit costs $28 for the 5-gallon size and $35 for the 120-gallon tank. The maker is The Tokheim Mfg. Co.

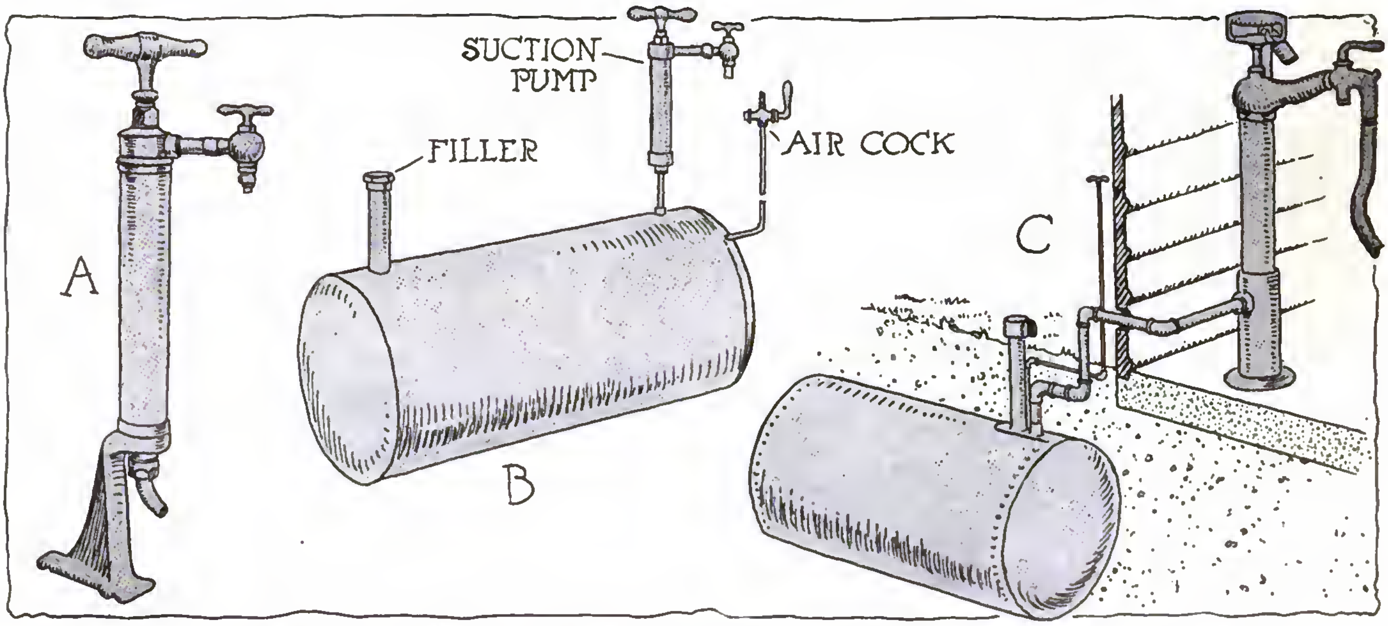

Fig. 12—A, gasoline pump for garage. B, complete underground outfit. C, method of installing tank with inside pump

Chicago Athletic Club Wins Record Run

CHICAGO, ILL., June 16—The sixth annual interclub team reliability match between the Chicago Athletic Association and the Chicago Automobile Club, run Thursday and Friday of last week to Waukesha, Wis., and return, was won by the former, making its record five out of six. The C. A. A. was charged with 57 points penalty, but this was reduced to 22 because of the credit of 5 points for each perfect score. The Chicago Automobile Club was demerited 515 points altogether, but it also had seven perfect scores and in addition was penalized only 9/10 of a point instead of a full point because it had ten contesting cars to the Cherry Circle's nine. This brought the C. A. C.'s final count down to 428.5.

The match brought out the finest example of sportsmanship ever exhibited in these annual matches. The Chicago Automobile Club was unfortunate enough to have on its team a man who totally disregarded the rule which prohibits the participation of women on the tour either as contestants, observers or passengers. Because George G. Greenburg carried two women passengers the first day of the tour the C. A. C. was penalized 250 points through the disqualification of Greenburg. The penalized driver refused to contest the second day unless he could carry the women passengers, so another 250 points were charged against the C. A. C.

Loaded down with this burden, the Automobile Club had little chance to win, but Captain Knisely of the C. A. A. was sportsman enough to offer to scratch two of his cars and take 500 points penalty in order to even up the match. The Automobile Club declined to take advantage of this and continued the contest. At the end of the match when it developed that the Automobile Club would have won if it had not been for the Greenburg incident, the Cherry Circle team pleaded with Referee Beecroft to change his ruling and consider Greenburg as a noncontestant. This that official refused to do, but he did wire the circumstances to Chairman Schimpf of the A. A. A. contest board and telling him of the wishes of the C. A. A. Chairman Schimpf, however, refused to make the change and said that the victory would be credited to the C. A. A., although the two clubs could make any disposition of the trophy they saw fit.

The score in detail:

Chicago Athletic Association

No. Driver	Car	Score
1—C. T. Knisely	Diamond T	Perfect
3—S. E. Hibben	Packard	Perfect
5—W. F. Grower	Diamond T	8 points
9—C. C. Ireland	Hudson	54 points
11—F. H. Judd	Knox	Perfect
15—W. C. Thorne	Locomobile	Perfect
17—Fred Schaaf	Pierce-Arrow	Perfect
19—F. E. Mann	Locomobile	Perfect
21—L. T. Jacques	Peerless	Perfect
Total penalty		57 points
Total credit		35 points
Final score		22 points minus

Chicago Automobile Club

No. Driver	Car	Score
2—G. F. Ballon	Apperson	Perfect
4—F. W. Jencks	Moline	Perfect
6—H. W. Sebl	Cole	Perfect
8—P. E. Ennis	Marmon	2 points
10—J. E. Callender	Edwards-Knight	Perfect
12—W. C. Wilson	Moline	Perfect
16—E. C. Patterson	Packard	Perfect
18—G. Greenburg	Packard	500 points
20—J. Dorsey	Alco	13 points
22—F. X. Mudd	Lozier	Perfect
Total penalty		515 points
Total credit		85 points
Final score		428.5 points

Hemery To Race at Elgin

CHICAGO, ILL., June 9—Participation of Victor Hemery, considered one of the best drivers in Europe, in the Chicago Automobile Club's road races at Elgin August 29-30, is assured by the announcement of E. C. Patterson, the Chicago sportsman, that he has completed arrangements for the entry of two poppetvalve Mercedes cars of 450 cubic inches piston displacement, one of which will be driven by Theodore Pilette and the other by Hemery. These two cars will be nominated for the Elgin national trophy race, which will be run the second day.

Elgin this year promises to be the most interesting of the series of races that has been run over the Kane county circuit. Already many entries are in sight. At Indianapolis it was announced that the three Isottas would be entered, with Harry Grant one of the drivers. Ralph de Palma, holder of the trophy, will defend his laurels, while Ralph Mulford is expected to contest in E. J. Schroeder's Mercedes. There is some talk of Goux's Peugeot being nominated, with some American star driving it.

Fairmount Park Race Is Dead

PHILADELPHIA, PA., June 12—The Fairmount Park race is officially dead. Once again had the hope of seeing automobile racing in the Park been revived only to be crushed to earth.

The action of the Fairmount Park Commissioners on Wednesday, when, by a vote of 7 to 2, the petition of the Quaker City Motor Club to conduct the annual 200-mile road race was rejected, conclusively proves that there is little prospect of restoring the classic to the automobile racing calendar under the present city administration. This is the second year the attempt has been made, but little encouragement attending either effort. Of the 16 members comprising the Commission 5 were absent and President Stotesbury and Mayor Blankenburg did not vote.

More Races for Milwaukee?

MILWAUKEE, WIS.—Rumors are being circulated in Milwaukee that the Milwaukee Automobile Dealers' Association is planning definitely to conduct road races on the Wauwatosa course next fall. The association conducted the Grand Prix, Vanderbilt, Pabst and Wisconsin cup races in October last year and lost about $45,000 in the attempt. It is figured that the remainder of this deficit could be made up by conducting another race meet.

PORTLAND, ORE., June 14—The total registration of motor vehicles in the state of Oregon for this year numbers 11,500, as against 8,411 this time last year. During the first 5 months of the year 11,048 motor vehicles were registered and 933 chauffeurs. The total fees amounted to $44,158.

Milwaukee Clubs to Compete

MILWAUKEE, WIS.—The Milwaukee Automobile Club will engage the Milwaukee Athletic Club in an inter-club reliability tour on Saturday, June 28. Each club will be represented by fifteen cars, instead of ten as originally planned, because of the large number of entries made. The route will be from Milwaukee to Lake Geneva, around Geneva lake and return, a distance of about 115 miles. The rules are lenient, and require that contesting cars must be driven by the owner or a male member of his immediate family. Penalties will be imposed for any work done on the car from the time of leaving Milwaukee until being checked in at night, with additional penalities for taking on water, gas or oil outside of control. The pilot work will be done by M. C. Moore in a White, while a 1913 Mitchell 6-60 will act as pacemaker and official car.

Le Mans Race to Be Run August 4

PARIS, FRANCE, June 11—Known as the Grand Prix de France, the 500 miles road race at Le Mans will this year be run on Monday, August 4, under practically the same conditions as the Automobile Club Grand Prix at Amiens. The course is a triangular one, practically dead level, with perfectly straight roads, passing by the racecourse on which the late Wilbur Wright made his first flights in Europe. Entry has already been received of two Peugeot cars now under preparation for the Amiens race. These cars will be driven by Jules Goux and Paul Zuccarelli.

Twenty-Two Now in Coast Run

INDIANAPOLIS, IND., June 17—There are now twenty-two entries for the Indiana-to-the-Pacific tour to be made under the auspices of the Indiana Automobile Manufacturers' Association and which will start from Indianapolis July 1. The association will have its last meeting before the beginning of the tour at the Claypool Hotel.

Wisconsin Tour Dates August 18-22

MILWAUKEE, WIS., June 16—The fourth annual Wisconsin reliability tour under auspices of the Wisconsin State Automobile Association will be held on August 18, 19, 20, 21 and 22, 1913, over a course of approximately 800 miles. The run will be held under grade 1 rules of the A. A. A., it having been

Inter-State License Bill Introduced

WASHINGTON, D. C., June 17—*Special Telegram*—A bill of importance to motorists was introduced in the House today by Chairman Adamson of the Committee on Interstate and Foreign Commerce. The bill provides that a motorist or operator of any self-propelled vehicle using the public highways in interstate commerce shall be required to take out only one license. If the bill becomes a law the license of one state, district or territory must be recognized by all others.

Cannot Save Privilege Tax Measure

JACKSON, MISS., June 16—*Special Telegram*—With the refusal today of the Supreme Court to grant a suggestion of error in the automobile tax case the last chance to save the privilege tax measure has passed. The $30,000 collected by the state will be refunded by a special act of the next legislature. The Supreme Court recently declared unconstitutional the privilege tax which had been imposed on all classes of motor cars.

Vermont Forbids Red Tail-Lights

MONTPELIER, VT., June 14—Vermont has taken the initiative in legislating rear lights showing a red disk off the highways in deference to the requests of locomotive engineers. Within the past few months engineers on some of the trains when rounding curves have suddenly seen a red light loom up at night, and after jamming on the brakes and stopping short discovered it was a motor car on a highway close to the railroad tracks. This happened a few times with the fast Boston and Montreal express, one of the big trains in New England, and so complaints were made to the Highway Commissioners in some of the New England states. The Massachusetts Highway Commission has promied to take the matter up before the next legislative session so that the example set by Vermont will be followed undoubtedly by all the other New England states next year.

The Vermont legislature also changed the law so that the secretary of state now has more power in the suspension and revoking of licenses, and he is provided with investigators to delve into accidents patterned after the Bay State law. This gives the secretary of state power to rule off the highways such persons as he deems unfit to drive motor cars. It provides for hearings when such drivers ask for them.

The legislature also passed a law limiting the weight of motor trucks. It provides that no vehicle including its load shall be moved over the highways or bridges in excess of 5 tons without first obtaining a written permit. No vehicle that has flanges, ribs, clamps or other objects attached to the wheels that will cut into the roads or bridges to any considerable depth may be moved over the roads. Towns may recover for any damage done by such vehicle unless the driver is relieved of the liability. No steam or gasoline traction engine with or without trailers and no motor truck carrying a weight in excess of 4 tons including the vehicle may be operated on highways or bridges at a speed greater than 15 miles an hour; no vehicle, including its load, weighing in excess of 6 tons may go faster than 6 miles an hour, when such vehicle is equipped with iron or steel tires, or faster than 12 miles an hour when equipped with hard rubber or other substance. The fine for violation of this provision is not more than $200.

Tice Roads Bill Passes in Illinois

SPRINGFIELD, ILL., June 6—The Tice good roads bill, for a system of state-aid highways through Illinois, carrying an intermediate appropriation of $700,000 annually for the next 2 years, was passed yesterday by the house by a vote of 111 to 33.

CONCORD, N. H., June 14—The New Hampshire legislature has passed a law for a new state highway that will cut off 25 miles going to or from Bretton Woods by way of Boston.

SAN FRANCISCO, CAL., June 13—The latest automobile record figures from California show that during the month of May, 1913, $7,596,000 was spent for machines in this state, there being 3,798 licenses issued.

The May registrations were the largest in the history of the state, indicating a flourishing condition in the trade. Since May, 1905, the sum of $215,396,000 has been invested in automobiles in California. Motorcycles are not included in this valuation.

BERLIN, June 13—The opening of the celebration of the 25th year of Emperor Wilhelm's reign, his silver jubilee, was marked by a parade of thousands of gaily decorated automobiles which was reviewed by the Kaiser on the suburban military review field. Prince Henry of Prussia, the Kaiser's brother, led the parade, the occupants of the cars cheering their ruler enthusiastically. Joseph C. Grew, secretary, and William Spencer, second secretary, of the American Embassy, drove their cars in the parade.

deemed advisable to go back to regulations which will insure a strenuous competition rather than a pleasure trip. The first two tours were run under grade 1 rules, but in 1912 it was decided to take a grade 3 run, and while a large entry list was secured, the tour was not as satisfactory from a competitive standpoint as it might have been under the stricter and more stringent grade 1 laws.

M. C. Moore, who has acted as pathfinder and pilot for every Wisconsin reliability run, will start Friday, June 20, on the pathfinding trip in a Mitchell.

A. A. A. Tour Pathfinder Leaves

MINNEAPOLIS, MINN., June 16—The Mitchell pathfinder car for the annual national reliability tour of the American Automobile Association left the Automobile Club in the Hotel Radisson at 2 p. m., June 15. Frank Zirbes was driver.

Algonquin Climb Postponed

CHICAGO, ILL., June 16—The annual Algonquin hill-climb of the Chicago Motor Club, which was scheduled for next Thursday, has been postponed. The reason given is that the hill is not in shape because of a new sewer that has been put in. Lack of entries is another reason for the postponement.

Mulford to Drive Peugeot Racer

NEW YORK CITY, June 16—The Peugeot Import Co., 1620 Broadway, New York City, announces that Ralph Mulford will drive the Peugeot racer, which won the 500-Mile Sweepstakes at Indianapolis, May 30, in practically all the big American speed contests this year. The car has been purchased by a wealthy sportsman who is interested in automobile racing and who has arranged with Mulford to drive it.

Franklin Nearest to Secret Time

SYRACUSE, N. Y., June 16—Edward F. Sparks, driving a Franklin, won the secret time sociability run of the Automobile Club of Syracuse, held Saturday, June 14th. The official time was 2:57:30, and Mr. Sparks was just 12 seconds out of the way, covering the route in just 2:57:18. This gives him possession of the B. E. Watson cup for one year and it is planned to have Mr. Sparks and the three previous winners of the cup hold a contest next year, the winner to have permanent ownership of it. Mr. Sparks also won 5 gallons of Monogram oil by coming in nearest the secret time.

COLUMBUS, O. ,June 17—Owing to inability to secure sufficient entries and also to the bad condition of bridges, due to the recent floods, the Ohio State Journal Reliability contest, which was to have taken place June 10, will be postponed until July 22.

SACRAMENTO, CAL., June 14—An American Scout was the winning automobile in the Sacramento-Tallac endurance contest, held recently under the auspices of a local newspaper.

Hupp Increases Capital

Raises It from $750,000 to $1,000,000—Makes Sixth Increase in Capital Since Incorporation

Action Taken by Company to Provide for Extension of Factory Equipment and Expansion in Organization

DETROIT, MICH., June 17—Papers have been filed with the Secretary of State at Lansing, increasing the stock of the Hupp Motor Car Co. from $750,000 to $1,000,000. This increase was made by a 25 per cent. stock dividend taken out of the surplus and added to the capital account.

This makes the sixth increase in the capital since the incorporation of the company, viz.: November, 1908, $2,500; December, 1908, $50,000; March, 1910, $25,000; June, 1911, $100,000; September, 1912, $750,000; June, 1913, $1,000,000. The last four stock increases have all been made out of the surplus on hand, in every instance leaving a comfortable margin of surplus in the treasury.

"We took this action," explained the president of the company, J. Walter Drake, "to provide for the extension of our factory equipment and the expansion in our organization made necessary by our preparations for the coming season. A conservative estimate as to the requirements of our dealers for the forthcoming season call for an output of 15,000 cars."

Grossman Company Wins Rajah Suit

NEW YORK CITY, June 16—The United States Court of Appeals for the Second District has affirmed the order in favor of the Emil Grossman Co., New York City, in the suit brought against it some time ago by the Rajah Auto Supply Co., Bloomfield, N. J., for selling repair porcelains for spark-plugs. The order issued by the court in the original suit was in favor of the defendant on account of proving that the defendant did not make it a business to sell such porcelains particularly for the complainant's spark-plug. The Rajah company appealed from this order, with a result that the order was affirmed. The original suit claimed an infringement on the part of the Emil Grossman Co. of the complainant's patent number 825,856. The decision follows:

This is an appeal from an order, which the complainant contends is a final decree, denying a motion to punish the defendant for contempt for an alleged violation of an injunction which enjoins the defendant from infringing the claims of complainant's patent No. 825,856 for improvements in spark-plugs. The defendant is not charged with contributory infringement in making and selling porcelain shells which can be used not only in connection with the complainant's spark-plug, but also in connection with many other spark-plugs dealt in extensively by those engaged in furnishing automobile supplies. The defendant asserts that the District Court was correct in denying the motion for the following reasons:

First. The decree appealed from is not final.

Second. There is no pretense of direct infringement and the selling of the conical porcelains with the intent that they be used in the complainant's spark-plugs is not proven.

Third. The evidence of infringing sales, upon which complainant relies, was obtained by letters induced by it which were answered by a typewriter in the defendant's office without the knowledge or consent of defendant.

Fourth. The matter of which the complainant complains is too trivial to justify the drastic remedy which the complainant invokes.

We do not deem it necessary to enter upon an extended discussion of these questions or to decide them. It is enough that the complainant's case is too doubtful, both on the facts and the law, to warrant the court in punishing the defendant for contempt.

The order appealed from is affirmed.

Asbestos Wins on Motobestos

NEW YORK CITY, June 7—The Asbestos and Rubber Works of America announces that after 2 years of litigation with the American Asbestos Co. over the trade marks "Motobestos" and "Motorbestos," the examiner of the patent office has allowed its claim to "Motobestos" as applied to motor car brake band lining and other asbestos-copper wire fabrics.

Managers for Columbus Buggy

COLUMBUS, O., June 16—Thaddeus C. Dunlap, a civil engineer, and George W. Lattimer, a druggist, have been named by the creditors' committee of the Columbus Buggy Co. to have charge of the management of the plant. The creditors' committee recently took over the plant from the receiver, who was discharged. According to the two managers, every effort will be made to save the big manufacturing plant for Columbus. It is the intention of the managers to continue the manufacture of both gasoline and electric cars for the present at least.

Receiver for Hartford Foundry

HARTFORD, CONN., June 16—The Hartford Foundry Co. is in receiver's hands, Edward C. Frisbie having been appointed temporary receiver. The company's trouble is said to have resulted from insufficient capital. The appointment was made on application of the Charter Oak National Bank, which holds notes for $27,000.

Cutting in Receiver's Hands

JACKSON, MICH., June 17—The Cutting Motor Car Co. of this city went into the hands of the receivers on June 2. The Security Trust Co. of Detroit, Mich., has been appointed receiver and the work of reorganization is now under way. It is stated that the receivership is a friendly one and that the reorganization should be in a position to resume business in the course of a few weeks.

Stuart Motor Corp. Retires Bonds

BUFFALO, N. Y., June 14—At a recent special meeting of the stockholders of the Stewart Motor Corporation, makers of delivery trucks, the company decided to redeem the $50,000 outstanding bond issue immediately. The stockholders also voted to convert $75,000 of the $250,000 common stock into 7 per cent cumulative preferred. $50,000 of the preferred stock has already been issued and paid for at par. This clears the corporation of all bonded indebtedness.

Large White Truck Sale

CLEVELAND, O., June 14—A very large motor truck sale was announced recently by the White Co., Cleveland, O., when the firm of Kaufman Bros., a prominent department store of Pittsburgh, Pa., purchased twenty-three White trucks of 1.5 tons and 1,500 pounds capacity.

Automobile Securities Quotations

NO decided recovery from the decline noted last week was apparent during the past 6 days. Rubber stocks still showed a slight falling off although this tendency was not so sharp as the week before, the bigget decline being that of Firestone common which dropped 8 points, making 37 points in 2 weeks.

English Engineers Disperse

Some Return to England while Others Remain To Make Closer Survey of Plants and Methods

One To Go on Indiana-to-Coast Tour and Another Accepts Position with Continental Motor

NEW YORK CITY, June 17—The small part of the members of the British Institution of Automobile Engineers which completed the itinerary as laid down in the official program, arrived here last Saturday. The party began to break up when the boat landed at Detroit after the lake session of the I. A. E. and S. A. E. At this point Messrs. Bennett, Buist and Ker dropped out. The next breaking-up point was at Detroit, where the party separated into three, one-third making the New England trip, a third going to New York and the rest scattering. Those making the New England trip were T. F. Benson, L. A. Bollack, J. B. Dunlop, C. A. Branston, J. B. Ferguson, E. Wooler, R. W. Smith senior and junior, E. C. Paskell, and Mr. and Mrs. E. B. Wood. The Messrs. Smith and Paskell dropped out of the New England party to make the trip to Springfield to see the works of the Hendee Mfg. Co., where Indian motorcycles are made.

One convert has been gained to the ways of America. Mr. E. Wooler has accepted a position in the drafting rooms of the Continental Motor Mfg. Co. and has gone back to Detroit. C. A. Branston is making the Indiana-to-the-Coast tour which starts July 1. T. C. Pullinger has returned to Detroit to make a further study of the plants in that city. J. B. Ferguson, Gilbert Moore, J. B. Dunlop, R. W. Smith and son, Charles Wheeler, B. Wood and wife sailed Saturday for home.

The New England trip embraced the following program:

Arrive Providence via Boston 10:15 a. m., June 11. Breakfast in Boston. The day will be spent in inspecting the works of Brown & Sharpe.

6.35 p. m.—Leave Providence, arriving in Bridgeport at 9.89 p. m. Dinner either in Providence or on the train.

Stratfield Hotel at Bridgeport.

Thursday, June 12

In Bridgeport

Visits to plants of Locomobile Company of America and Spring Perch Company.

Locomobile Company of America host at luncheon.

Motor car drive to New Haven, arriving at 2.80 p. m.

Visit to works of New Haven Carriage Company.

Night at Hotel Taft, New Haven.

Friday, June 13

9 a. m.—Leave New Haven by motor car for Hartford.

Visit to plants of Pratt & Whitney, Pope Manufacturing Company and Hartford Rubber Works.

4 p. m.—Leave by boat for New York.

Indiana S. A. E. Elects Officers

INDIANAPOLIS, IND., June 16—At a meeting of the Indiana branch of the Society of Automobile Engineers held at the Claypool Hotel, Indianapolis, on the evening of June 10, officers were elected as follows: Chairman, R. C. Coombs, Prest-O-Lite Company; secretary, C. P. Grimes, Wheeler & Schebler, and treasurer, John Wood, of the Remy Electric Co., Anderson. George A. Weidley, of the Premier Motor Manufacturing Co., the retiring chairman, was elected vice-chairman.

Calder Heads International Motors

NEW YORK CITY, June 17—An election which has just been announced by the International Motors Co. makes a change in the higher officers of the company. John Calder, former first vice-president, has been elected to the presidency of the concern, and R. E. Fulton becomes the first vice-president. Mr. Fulton was formerly the general sales manager.

Schacht Truck Company Incorporated

CINCINNATI, OHIO, June 16—The G. A. Schacht Motor Car Co. has been incorporated with $25,000 capital by Gustave A. Schacht and Charles Talbott. The company will manufacture motor trucks only. Temporary headquarters have been secured out on Spring Grove avenue, near the Schacht Motor Car Co., of which Gustave Schacht was the former president.

To Raise All Insurance Rates

HARTFORD, CONN., June 16—Insurance premiums for all classes of automobile risks are going to cost more in the very near future. Hartford companies as well as others throughout the country are prepared to raise the price. The contention is that automobile accident insurance is now sold too cheaply and the beneficiary gets too much for what he pays. The rise in price will affect 1914 business.

Walk-Out in Studebaker Plant

DETROIT, MICH., June 17.—More than 3,000 men employed by the Studebaker Corporation, in its local automobile plants struck today. The men said the walkout was the result of repeated demands for weekly pay, instead of bi-monthly. The strikers claim that the employees in the other automobile factories in Detroit will act in sympathy with them. The company states that the strikers merely seized upon its refusal to re-instate a discharged employee as a pretext, several I. W. W. men having been trying to incite a strike in the automobile plants for some time.

Goodyear to Establish Tire Stations

NEW YORK CITY, June 16—C. W. Martin, manager of the motor truck tire department of the Goodyear Tire & Rubber Co.'s New York City branch, states, regarding the company's recent announcement of a chain of motor truck tire service stations to be established throughout the large cities of the country, that the time taken up by tire changes has been found such a handicap by truck owners, whose loss on the investment in an idle truck was heavy, that the Goodyear company adopted the day-and-night service station as the remedy.

Market Changes of the Week

Another break in tin occurred again this week, followed by extreme dullness and caution in the local market. There was scarcely enough trading in the open market to establish prices. Tin was selling at $45.30 per hundred pounds on Wednesday and stearily rose therefrom to $45.85 on Saturday. From then on to Tuesday there was a gradual decrease, closing at $44.66, a loss of $.64. A further sharp decline is expected. Lead was stronger in tone, rising $.05 per hundred pounds. Both Lake and electrolytic coppers declined, the former $.00 1-8 and the latter $.00 1-5. Antimony, beams and channels, Bessemer steel, and open-hearth steel remained constant. Both silks from Italy and Japan rose, the former $.10 and the latter, $.02 1-2. Tire scrap remained steady at $.10 per pound.

Material	Wed.	Thurs.	Fri.	Sat.	Mon.	Tues.	Week's Change

Haynes for 1914 Is Out

Line Consists of Four and Six-Cylinder Models, All of Which Are To Be Fitted With Vulcan Electric Gearshift

KOKOMO, IND., June 17—The Haynes Automobile Co., of this city has today announced that it will equip its entire line, consisting of four and six-cylinder models, for 1914, with the Vulcan electric gearshifter, which device the company has tested out on its six-cylinder cars for several months to its utmost satisfaction. This announcement of America's pioneer maker fitting a gear shifter device as stock lends much force to the arguments advanced favorable to some form of gearshift other than the lever. Although the Haynes company has made this equipment stock it will fit the lever shift system if requested, and in which case the gearshifter quadrant will be under the car floor and the lever in the center of the floor board for right-hand operation.

In experiments extending over months the electric gear shifter has given entire satisfaction, the engineering force claiming successive hundreds of operations without a miss. In recent tests it has made over 500 changes in a single day without any difficulty being experienced.

The control of the gearshifter is on a circle above the steering wheel. On this circle are seven buttons for use as follows: Three for forward speeds, one for reverse, one for neutral, one for the electric starter and one for the electric horn. A button takes the place of the gearshift lever.

The Haynes company has had the question of electric gear shift under consideration for some time and was the second motor car concern to sign contracts with the Vulcan people for its equipment. The operation of this gear-shifting arrangement was illustrated and described in THE AUTOMOBILE for April 3, page 778. In this device solenoid coils are employed as the system of control. There is one of these coils for each speed. Two speeds cannot be engaged at once because each speed is governed independently of the others and an interlocking device provides that no two buttons in the control can be down at the same time. Should the second speed button be set and the driver decide that he wants to go into third, he merely presses the third-speed button which returns the second speed one to its normal position. Pressing the neutral button leaves all of the others normal. Specific details concerning the exact method of application will be published later.

The Haynes company will market two 1914 models, a four and a six, both alike in general details of design and using the same cylinder sizes, 4.5 inches bore and 5.5 inches stroke. The cylinders are cast in pairs and have the valves on one side only as introduced on the 1913 six. Ignition is by Simms magneto with one set of plugs. Pressure gasoline feed is introduced, the gasoline tanks being supported on the chassis in the rear. Pressure is maintained by an automatic air pump driven from the camshaft and there is also a hand pump on the dash. Lubrication is by a circulating splash system.

In the motors bearing surface for the crankshaft has been given good attention. On the four-cylinder car, three bearings are used, giving a total bearing length of 11.5 inches. The crankshaft is 2 inches in diameter and the 11.5 inches length is distributed 3.75 in front, 2.5 for the center, and 5.5 at the flywheel. On the six-cylinder model four bearings are used, giving a total bearing length of 14 inches, the dimensions being practically the same as in the four, excepting that an additional center bearing is used.

The chassis details incorporate the standard Haynes contracting type clutch. In the four-cylinder car the McCue axle is used in front and rear, on the six-cylinder, Timkens. An entire new line of bodies has been added, these being die-formed types in which a cowl is used. The cowl curves down and meets the hood which is in reality a continuation of it. A clean-cut appearance is obtained by not using side-dash lamp brackets, rather the dash lights are carried on unions which attach to castings within the cowl. The clean-cut appearance is further accentuated in that there is no visible support for the wind shield on the cowl, but it is, nevertheless, secured to a casting within the cowl. The cowl on all models is alike and is a one-piece, die-formed part.

On the four-cylinder cars open bodies are made with two, four and five-passenger capacity. On the six-cylinder chassis open bodies are made for two, four, five, six and seven-passenger capacity. The six-cylinder chassis is made with two wheelbases, one 130 inches and the other 136 inches. The limousine body is fitted to the latter. On both fours and sixes a line of four-passenger coupé bodies is supplied, these being from the factory of Biddle & Smart.

Externally, all bodies are given a cleaner appearance in that the running boards are entirely free from incumbrances. The battery used for lighting, starting and gear shifting is located under the chassis. It is claimed to have adequate capacity for 1,200 starts and approximately 4,000 to 5,000 gearshifts, the current consumed in gearshifting being very slight. A full electric lamp equipment is used.

Hudson Vice-President Invades Europe

PARIS, FRANCE, June 13—F. O. Bezner, vice-president of the Hudson Motor Car Co., has taken up his residence in this city with the object of directing a business campaign for Hudson interests throughout the Continent of Europe.

Packard Adds Two Truck Models

DETROIT, MICH., June 17—The Packard Motor Car Co. has added two more models to its line of motor trucks, these being of 4 and 6 tons capacity. Heretofore models 2, 3 and 5 tons capacity have represented the company in the commercial car field, and the newcomers will thus broaden the range. The specifications of these two new Packards are along the same lines as the others and show no deviations from the company's truck practice. The motors develop 32.4 and 40 horsepower, respectively, according to the S. A. E. rating. They are T-heads and transfer their power conventionally to jackshafts, the final drive being through side chains.

The wheelbases are 144 inches for the 4-ton and 168 inches for the 6-ton, while a wide range of optional bodies is offered. The prices are set at $3,550 for the lighter of the two and $4,650 for the 6-ton, while in either case an extra long chassis is furnished at $100 extra.

Sanatogen Decision Stirs Manufacturers

NEW YORK CITY, June 14—Manufacturers affected by the Sanatogen decision of the United States Supreme Court have combined in a league to protect the prices of patented articles. No definite action has been taken as yet except the establishment of a permanent organization with Henry B. Joy, of the Packard company at the head of the executive committee. Other automobile men on the committee are A. Erlanger and A. Lucking, both of the Ford company. The remainder of the committee consists of T. F. Murphy, of Mark Cross; E. T. Welch, of Welch Grape Juice Co.; W. K. Kellogg, Kellogg Toasted Cornflakes Co.

New 1,500-Pound Republic Truck

DETROIT, MICH., June 17—The Alma Motor Truck Co., recently organized to take over and continue the truck manufacturing business of the Alma Mfg. Co., of Alma, Mich., recently placed on the market its new 1,500-pound model Republic truck. This company is listing the complete truck with the choice of two standard bodies at $1,425.

DETROIT, MICH., June 17—H. L. Adams has taken over the general managership of the Detroit plant of the Edward G. Budd Mfg. Co., Philadelphia, maker of steel bodies. T. H. Millington has managed this plant up to this time.

Many Americans to Show at Salon

PARIS, FRANCE, June 11.—Paris this year opening the European show season with its salon on Friday, October 17, there will doubtless be a stronger international representation than on previous occasions. Although official applications for space will not be received until next week, there have been several inquiries from American firms and the probabilities are that there will be a big showing of cars from across the Atlantic. The Packard Motor Car Co., which, although having a store in Paris for a number of years, has never been able to secure a position in the show, will put in an application for a central space. The Hudson Motor Car Co. intends to take a big stand. Others to be represented are Ford, Buick, Cadillac and R. C. H. The new Briscoe car, now being produced by Mr. Benjamin Briscoe and a special staff of American and European engineers, will make its first bow to the public at the Paris salon.

The White Co. branch and district managers meet in annual session. Top row, left to right—W. F. Moore, Pittsburgh branch manager; A. R. Warner, secretary the White Co.; W. J. Urquhart, Chicago branch manager; J. A. Bell, retail manager, Chicago branch; E. W. Gans, Atlanta manager. Middle row—J. E. Huggins; Walter C. White, vice-president and sales manager the White Co.; Windsor T. White, president the White Co.; J. Rathbun, New York State district manager. Bottom row—J. A. Howley, Philadelphia branch manager; M. Fellows, Eastern Canada representative; J. S. Hathaway, Boston branch manager; G. A. Urquhart, southwestern district manager; R. H. Johnston, New York branch manager

Entrance to Automobile Show in St. Petersburg

Russia's Great Show

Tsar's Government Favors Rapid Automobile Development and Seeks Type of Vehicles Suited for National Russian Needs

RUSSIA wants automobiles and wants them on a scale commensurate with the extent and resources of Russian territory. The Muscovite empire is the only country where the government is more anxious to have the citizens own automobiles than they are themselves. The transportation problems now arising in connection with the rapid development of agriculture and industry which is taking place in the realm of Tsar Nicholas, are among the most important ones to be solved and must be solved with all possible despatch, and it is the ruling opinion that motor vehicles are to play a decisive part in their solution. The railroads are not numerous, and there is little desire for a railroad development, like that of the United States, which tends to transform all classes of the population into travellers. Russia would rather build highways than gridiron her prairies with steel tracks. It is therefore the intention to give the motor truck something more than a fair field and no favor, so far as the short and the medium length hauls are concerned. The owners of large country estates, in whose domains industrial establishments are also frequently located, take a similar view. They would rather have the railroad station 60 miles away than at their doors, carrying trouble to their little sub-kingdoms. They would like to drive to and from the station in automobiles of their own and at the dizziest clip. The fast automobile suits their average temperament. exactly but so far they have not been able to find cars that would stand the gaff of the by-roads, frozen and rutty as they often are. They are earnestly looking for durable trucks and for fast and robust cars and are willing to improve the roads meanwhile as fast as the economical development justifies. In this search and these intentions their government is with them, being composed of men of the same views and standing in need of the same things for military purposes,

The second international automobile show which was held during the closing weeks of May under the arched glass roofs of the spacious Imperial riding school building in Saint Petersburg was an evidence of the energy with which these desires for promoting automobilism and motordom in Russia are followed up; for no exposition of similar scope and importance has been held in any other non-producing country; and Russia has only two small automobile factories of her own.

This show was opened with pomp and ceremony. The picturesque hierarchy of the Russian church, with processions, ikons, chants and invocations, united with state officials to place upon it the stamp of approval from spiritual as well as temporal authority. The French ambassador improved the occasion to have cemented anew the Franco-Russian alliance. An imbroglio with Germany, whose manufacturers are eager for the promising Russian trade and who view with extreme jealousy all the shrewd efforts of the French at monopolizing it on political grounds, was suavely averted.

In all 65 exhibitors bid for the business. They were distributed, according to nationality, as follows:

Germany	26	Belgium	4
France	17	Russia	2
England	9	Switzerland	2
Italy	6	Sweden	2
United States	6	Austria	1

It is admitted by both German and French exhibitors, in so far as their voices have reached the press, that the number of orders booked at the exhibition left a good deal to be desired. Prospective purchasers were still hesitating. American advance agents, on the other hand, report better luck. The comments of a well-informed French visitor may furnish a clue to the understanding of this discrepancy. He says that vehicles must be furnished with all equipment, that the powers from 12 to 20 are at present most readily sold, that the vehicles must have large ground-clearance and that the body must be made to accord with Russian taste and customs, as the purchasers insist upon having plenty of the home color in their conveyances. Those wishing to establish agencies should remember that Russia has two capitals, Petersburg and Moscow. The latter, while not the seat of government any more, is the home of immense fortunes and of much distributed wealth—the better market of the two cities. The Russian car owner is fortunate, he adds, in not being bothered by speed regulations or exhaust smoke ordinances. He must conform to certain traffic rules, and very strictly at that. The police see to it that he does so, but his ignorance of the rules is no crime. Only if any fault on his part causes an accident it goes hard with him.

Accounts Not Secure

One trouble with the trade in Russia, says a German commentator on the situation, is the insecurity of accounts. The Russian merchant is very remiss about paying them on time or at all. Last winter European importers had sad experience of this nature in southern Russia. The merchants had to carry the farmers over, by reason of crop failures, and in turn simply omitted to meet their own obligations. Local committees comprising the more substantial elements among the merchants have now been formed, however, and in conjunction with banking organizations, expect to remedy this situation. Suitable laws are being passed to the same end. It is characteristic that the total of deposits in Russian banks amounted to 1,800 million rubles at the end of 1911 and had risen to 2,200 million rubles at the end of 1912.

Before the opening of Russia's international show—everything ready

Europe Demonstrates Trucks

ALMOST immediately after the American truck makers announced in unequivocal terms that they do not want any truck shows in New York or Chicago next winter at the time of the passenger car show, England announces that she is resurrecting her truck show after a 3-year sleep and France has announced its exhaustive trials under the direction of the war office. In Europe, every truck maker is up in arms for shows and demonstrations. At Olympia, in London, all space was sold weeks ago and the exhibition gives promise of being the best truck exposition Europe has ever seen. Across the English Channel the military trials in France are going to be record breakers. Already ninety-six trucks and over a dozen tractors are entered.

To America the question is "Are we on the right track?" From indications it would seem that we are not, rather that we are traveling in the opposite direction.

We have closed the doors on shows. We shut the doors last year on competitive demonstrations. What is the result? Today a few truck makers are working very earnestly to make sales. They find it hard work. They are having the same experience European makers had when they closed the doors on shows and trials. American makers are finding out and will continue to find out that shows and competitive demonstrations are good when sanely conducted.

Leverless Gearshifting

THE announcement made in other pages of this issue on the use of the electric gearshift by the Haynes company, one of America's pioneer manufacturers, together with the fact that one of the other leading companies may adopt it, corroborates what THE AUTOMOBILE stated editorially over a month ago, namely, that leverless gearshifters are bound to come just as soon as they can be rendered commercial from a manufacturing viewpoint. It is now a settled question that two concerns will equip them as stock for next season and it has been known definitely for several weeks that a few other concerns have been submitting blueprints to gearshifter concerns, with the avowed object of making such stock equipment for next season.

The leverless gearshifter is bound to come, it is a natural sequent to the self starter, demountable rims and electric lights as well as lighting devices for gas headlight systems. Of these four the leverless gearshifter occupies perhaps first place from the viewpoint of being a work eliminator. There is a hundred times more gearshifting than there is lighting. There are tens of times more gearshifting than starting, particularly in city driving. There are hundreds of times as much gearshifting as tire changing. Because of the great number of gearshifts the leverless gearshifter will be generally welcomed from coast to coast.

When demountable rims were put on the market, it was then argued that woman would be given an opportunity to drive anywhere. The self starter added immeasurably to her cause; but it is questionable if the gearshifter will not be a greater boon than either of them. Gearshifting has often been a hardship with the woman driver, particularly for city driving.

As previously pointed out in these columns, the leverless gearshifter will do excellent service to the car mechanisms, in that there will be more gearshifting than with the lever system. It is but rational to assume that such will be the case, because the movement has been simplified and practically reduced to the automatic zone. Not a few drivers have not shifted gears sufficiently, partly because they objected to being seen making the shift and often because of the difficulty of it. The leverless system will largely remedy this.

The small-capacity motors that are now being fitted together with heavier bodies demand more gearshifting than in the past. The leverless system, it is hoped, will be a step in the accomplishment of this.

The many arguments that were advanced against self starters because of added weight cannot be brought forward in the leverless starter because little additional weight is needed. The battery for operating the gearshifter is the same as used for the starter and the lighting system, and the leverless system has eliminated a few of the mechanical parts and added lighter ones to take their place.

It is difficult to gauge just what the status of leverless gearshifting will be during the next year. Although the electric type has been most in the spotlight recently, other types are coming to the fore and some interesting developments are promised for the future in electric, pneumatic and other types.

England Has Live Engineer Institution

THE Institution of Automobile Engineers of Great Britain, members of which were the guests of the American Society of Automobile Engineers, is an organization of 783 members made up of engineers in motor car factories, professors in colleges, car owners engineeringly inclined and college graduates interested in motor car work. The institution has headquarters at 13 Queene Anne Gate, the center of the consulting engineering world of London.

The Institution of Automobile Engineers used to be known as the Cycle Engineering Institute, but was changed to its present name in 1907, at which time it was incorporated.

The I. A. E., as it is familiarly known, has four grades of members: These are members, 271; associate members, 251; graduates, 219; and associates, forty-two; a total membership of 783.

The work of the society is under the direction of a council of thirty, but the direction and general management rests with the secretary, which position has been held for several years by Basil H. Joy, who devotes a large part of his time to the work of the institution.

Basil H. Joy, secretary of the I. A. E.

The work of the I. A. E. is accomplished by its monthly meetings, held in London from October to June, at each of which one paper is read and discussed. The majority of the papers are prepared by members, but occasionally outsiders are asked to contribute. These papers are carefully criticized and edited before being printed and circulated through the membership prior to the meetings. The average attendance at these monthly meetings is between 175 and 200 and all sessions are very animated.

Although the distances in Great Britain are vastly less than in America, the I. A. E. has found it necessary to organize branches throughout the country for the convenience of those who cannot get to London for the monthly meetings. The North of England branch, which meets at Manchester, covers a zone of country extending north and east of that city. There is being organized at present the Midlands branch, which will hold meetings alternately at Birmingham and Coventry. In addition, the members in Scotland are at present urging the formation of a Scottish branch, with headquarters in Glasgow.

The class of membership designated Graduates has three branches of its division located in London, Coventry and Birmingham. Meetings are held in these centers once a month and the branches have their own chairmen and honorary secretaries. An example of the work done by these graduates was the recent preparation of a series of eight papers by the London graduates dealing consecutively with the steps necessary in the output of 750 chassis, of a 15-horsepower car to be sold at $1,750. One paper dealt with design, the second with purchasing materials, the third with the drawing office, and the others with various aspects of the production of such a vehicle. The series proved of immense interest and led to the graduates securing a vast amount of information on production and design which is not found in text-books.

Another recent work of interest by the graduates was on the training of engineers. The scope of the paper covered the various practical aspects of the question. How should the courses in technical and shop training be arranged? Which should come first? What studies should be included? Should a student be educated in a motor car shop or in a general engineering plant? Various other questions relative to training were taken up and discussed at more or less length.

During the last few years the I. A. E. has given much attention to the training question and has established a bureau of information for the guidance of parents who wish to have their boys take an automobile engineering course. This bureau has compiled the arrangements from the various factories as to their requirements for under-engineers and also the possibilities for graduates in their plants.

While the major efforts of the American Society of Automobile Engineers have been devoted to the work of standardizing car parts and processes of manufacture, the I. A. E. has not been nearly so active. In fact, it only took this work up actively a year ago. Although the recognized motor engineering institution in England, the work of standardizing motor car parts does not come under the I. A. E., but it is working indirectly to accomplish the same results as the S. A. E. is accomplishing in this country.

In Great Britain the entire work of standardization rests with the Engineers' Standards Committee, a private institution subsidized by the British government and which handles the question of standardizing for the entire nation. It has determined the standard sizes of railroad rail sections, and has gone into the standardization work of all the industries in the land. The committee has been in existence for years. It is divided into sections representing the various industries, one of which is the motor car section appointed last year. The various motor organizations of Great Britain are represented on this section, some of these organizations being the I. A. E., the Royal Automobile Club, the Automobile Association and Motor Union, the Society of Motor Manufacturers and Traders, etc. This section has already met and roughly determined on what parts of the motor car can be standardized. The section then subdivided itself into as many departments as there are car features to be standardized. These sub-committees are collecting data on standard practices of today, so that they can organize these data into a definite report to the Engineers' Standards Committee. The work is progressing much as in America and practically along the same lines, excepting in that the final word on what shall be standardized does not rest with any one automobile organization, but with the main committee of the nation. The 1913 visit to America was the second one of the I. A. E.

Motor Trucks in Cincinnati Strike

CINCINNATI recently experienced one of the most complete street car strikes in the history of the country. Not a car wheel turned for days. Then when efforts were made to revive the service with cars manned with strike-breaker crews the sympathizing public refused to ride on the cars. Yet they did not walk. The solution for the thousands who were thus deprived of street car service was the motor truck. Every motor truck in the city worked either all or part of every day as a street car. Motor truck coal wagons, motor truck beer wagons and motor trucks used for any kind of hauling at once became passenger cars, and some of them were earning for their owners as high as $175 a day hauling suburbanites to and from their homes at from 15 to 25 cents a passenger, according to the distance they wished to travel. If it had not been for these swift, modern motor trucks the problem of how to get to and from home, with thousands of people living in suburbs from 5 to 10 miles from their places of employment, would have been a serious one, for not all Cincinnatians own automobiles. Yet it is estimated that the automobile took care of one-fourth of the people who used the street cars before the strike. Motor truck service sprang up 2 hours after the street cars suspended operation. At first only two trucks appeared for duty. The idea of hauling passengers spread like wild fire among motor truck owners, and business firms suddenly realized that a new and highly profitable business was suddenly thrust upon them. The public was quick to appreciate this as can be seen from the illustrations.

New York City's Big Civic Parade

THE Civic Parade held in New York City on May 17 brought out a large percentage of the city's motor vehicles used by the various departments. A majority of the municipal vehicles are propelled by gasoline, while a few are of the electric type. Eighteen different departments were represented by 557 vehicles, a majority of these being self-driven. The total number of fire department vehicles used by the city is 895. About 16 2/3 per cent. are motor-driven, and the rest are horse-drawn. These motor-driven vehicles are divided into fire engines, hose wagons, hose wagon-combination, chemical engine wagons, trucks, supply wagons, ladder wagons, chief's wagons and the water towers. The hospital equipment includes fifty-five vehicles, sixteen of which are electric and the rest gasoline. Much of this equipment is from the factories of the automobile industry where standard chassis are fitted with bodies suitable to the requirements. The police department is represented by eight self-propelled vehicles, one being motor-driven and the rest of the electric type. These are divided into patrol wagons and passenger cars. The lighting and power department uses four trucks, two of them for the men who trim the lamps and the rest in the transportation of supplies. There are five different makes of trucks in service for the waterworks division. These are used in repair work and the transportation of supplies. The sewerage and sanitation equipment consists of two trucks for the transportation of supplies. A few of the departments pay off the employees in automobiles The government finance division has two wagons in this capacity.

The Engineering Digest

The Making of a Double-Closing Poppet Valve by Near-Automatic Methods—Nervous Motors on Verge of Knocking; Quick Cleaning Saves Them

Cheap Synthetic Acetone Craves Attention of Oil Refiners for Benefit of Motoring Public—Proposed Improvement of Oxy-Acetylene Burners

HOW the Adler Silent Valve Is Made.—Though the clattering noise arising from the opening and closing of ordinary poppet valves plays only a small part in the general mechanical scheme for silencing the operation of a car—now that the camshaft and the valve are both usually inclosed and the sounds they make therefore muffled—suitable methods for having the valves open and close gently and without making any sound that needs to be muffled are considered of some importance in the matter of avoiding wear, vibration, hammering of the conical valve and valve seat surfaces and disintegration of the valve stem at the weld. The poppet valve design which has been most frequently mentioned as notable in this respect is the one originated at the Adler works at Frankfurt-am-Main. The production methods applied in the making of this valve are now also referred to as an example of advanced German mass-production practice, and the subject thus gains a double interest. The different stages in the manufacture are fully represented in the accompanying illustrations, Figs. 1 to 11. With regard to the principle of the design it may be said that the closure effected by the seating of the mushroom is supplemented by a cylindrical fit of that part which forms the special feature of the valve, and four guide ribs are employed to steer this short cylindrical portion, *h* in Fig. 1, safely into the valve bore in the cylinder wall. The preliminary closing by means of *h* admits of reducing the speed of the subsequent valve motion considerably by means of a very gradual drop-curve of the cam, while the first part of the motion can be as rapid as desired. The rising-curve of the cam can also be made gradual, for the same reason.

Fig. 2 shows the blank for the valve proper. It is cut from bar steel on a slicing-lathe. This blank is dropforged, obtaining the shape shown to the left in Fig. 3, and, after removal of the burr, a piece of half-inch round rod is welded to it, the end of the latter being first slightly upset. as shown in Fig. 3, and the welded piece is then turned down, Fig. 4. The roughing is now done on a lathe with a toolholder holding four tools, one for rough-turning the valve stem *a*, a tool shaped as shown in connection with Fig. 5 for forming the tore *b*, another shaped tool for the outer surface *c*, while a side-cutting edge is used for *d*. A vertical milling machine is used for generating the guide ribs. Fig. 6 indicates the method followed. The valve stem is held in horizontal position between the jaws of a vise secured to the table of the milling machine, and to this table there is also secured a template *Sch* which is moved along a guide rod S. By this arrangement the end mill F which works at a constant distance from the guide rod S, mills the guide ribs out of the material and brings them to the shape shown in Fig. 7.

In Fig. 8 the piece is shown turned down on a screw-cutting lathe so as to be ready for grinding. In order to avoid the forming of a fin at the grinding of the stem, the portion of the latter immediately under the mushroom has been designed 0.2 millimeter smaller in diameter than the final measure of the rest of the stem, which is 9 millimeters. Fixed maximum-and-minimum calipers serve for controlling the exact diametrical dimensions, while the lengths are justified by angle rest fences on the lathe bed.

In order to be able to grind the valve cone, a slot is formed in the valve body as indicated in Fig. 9, the tool used being a circular saw chucked in a horizontal milling machine. The slot in the valve stem is formed in a groove-milling machine, the stem being held in a vise as in Fig. 6. Before the grinding, the valve cone receives its final turning down on a lathe in which the stem is mounted in a self-centering chuck, as in Fig. 10. Thereafter the stem is ground to exact measure, the cone portion being mounted in an exactly fitting sleeve which is secured to the face plate and in the bottom of which there is a projecting rib, corresponding in shape to the slot in the cone valve top and acting as driver and, by a similar arrangement on the face plate of a lathe, the valve stem is finished to exact length, the result of these final processes being shown in Fig. 11.—From *Werkstattatechnik*, May 1.

ANALYSIS of Knocking; Its Cause and the Remedy.—The conservatism of American manufacturers in accepting the modern "nervous" type of motor with long stroke and high compression, and placing it in the hands of the motoring public, only with such deliberate slowness that its peculiarities, relating to operation and maintenance as well as to details of construction, may be mastered gradually, frequently receives indirect commendation in the reports of troubles experienced in those foreign countries, especially France, where the transition from the comfortable low-compression motor of relatively low speed, small valves, rapidly declining volumetric efficiency and indifferent fuel economy to the more modern type has been carried into practice with radical and ruthless consistency by a number of firms whose reputations were still to be made—as compared with those of the few *grandes marques*—and who were satisfied to pin their faith to the undeniable theoretical superiority, in the way of power and fuel saving, which the new type has been shown to possess, and even to possess permanently without any serious accompanying drawbacks, provided the design and construction are just right and care and maintenance are bestowed upon it in some proportion to the more delicate adjustment of the working factors in the motor mechanism.

An analysis of the causes of knocking in modern motors presented by Henri Petit bears on this subject in a popular manner. He writes in substance as follows:

The motors with high compression which are fitted to modern vehicles are subject to a malady of which knocking is one of the symptoms. All drivers know what the knocking of a motor is: That dull sound which the ear perceives when the motor is slowed up by its load and when the spark is too much advanced. It sounds like the blow of a hammer on some soft metal, as lead.

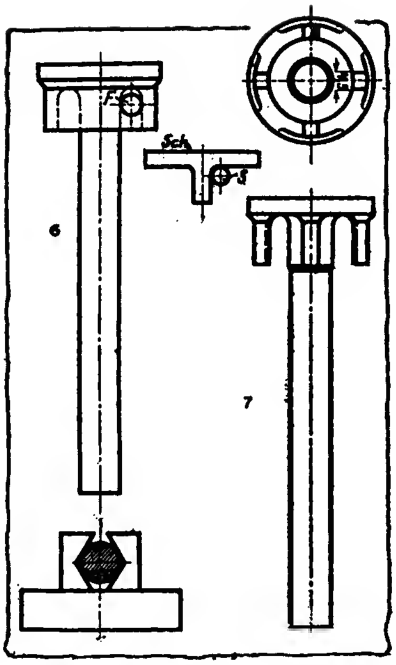
The cause of knocking can nearly always be traced to an abnormal pressure in the combustion chamber at the moment of the explosion and in other cases to abnormal play in the joints of the connecting-rods. Some readers may wonder at the use of the word abnormal with regard to the play. There should, then, normally be some play in these joints, they may say, and yet it has been said and repeated so often that there should be no play at all in the joints of a motor. The fact is this injunction, as may readily be shown, is inaccurate. The movement of two rubbing surfaces is impossible unless there is some play between these surfaces. Imagine, for example, that a solid cylinder A and a hollow cylinder B are made as nearly as possible of the same diameter; say, that the difference in the diameters does not exceed a one-thousandth part of one millimeter. Now, if one tries to insert cylinder A in cylinder B, this operation is found to be radically impossible. If we reduce the diameter of cylinder A until the insertion becomes possible and then measure this new diameter, we find that it is at least 3 to 4 hundredths of a millimeter smaller than it was before. While our senses may not be able to perceive it, there is, then, always play between two perfectly fitted cylinders.

But now, if we coat these two perfectly fitted cylinders with oil, separately, it is again found impossible to insert one in the other. To accomplish the insertion it is necessary to reduce the diameter of the solid cylinder again, this time 6 to 8 hundredths of a millimeter. And if we wish that cylinder A shall be able to revolve readily in cylinder B, lubricated with oil, the play must be still larger.

It is thus clear that the mere fact that the crankshaft can be turned around in the lubricated bearings of an absolutely new motor which never has been worked affords positive proof for the assertion that there is play in all of its joints, but despite of this play one cannot shake the crankshaft in its bushings; by pulling on the connecting-rod, for example. The oil film acts as a veritable cushion and cannot be displaced except by a very violent and prolonged effort. The shock which the rapid combustion of the explosive mixture produces against the top of the piston is not sufficient to shake the joints if the initial play has been suitably calculated and if the lubricant possesses great viscosity.

But if, for one cause or another, the intensity of this shock is increased and if the lubricant becomes too fluid. as will happen when the motor becomes hot, the connecting-rod will be displaced with relation to the shaft, the oil film will be pushed out of joint and the metal of the bearing will be brought in contact, with that of the shaft with a blow. Hence the knocking.

The effects of knocking are decidedly destructive. In the first place, the metals brought in contact are, for the moment, no longer lubricated and turn dry for a certain fraction of a revolution. There is sure to be heat generated, and seizing is possible. Besides, each blow produces a flattening of the relatively soft metal of the bushings, which are thereby ovalized. Play produces play, as it is customary to say. A motor which knocks is therefore doomed to rapid deterioration.

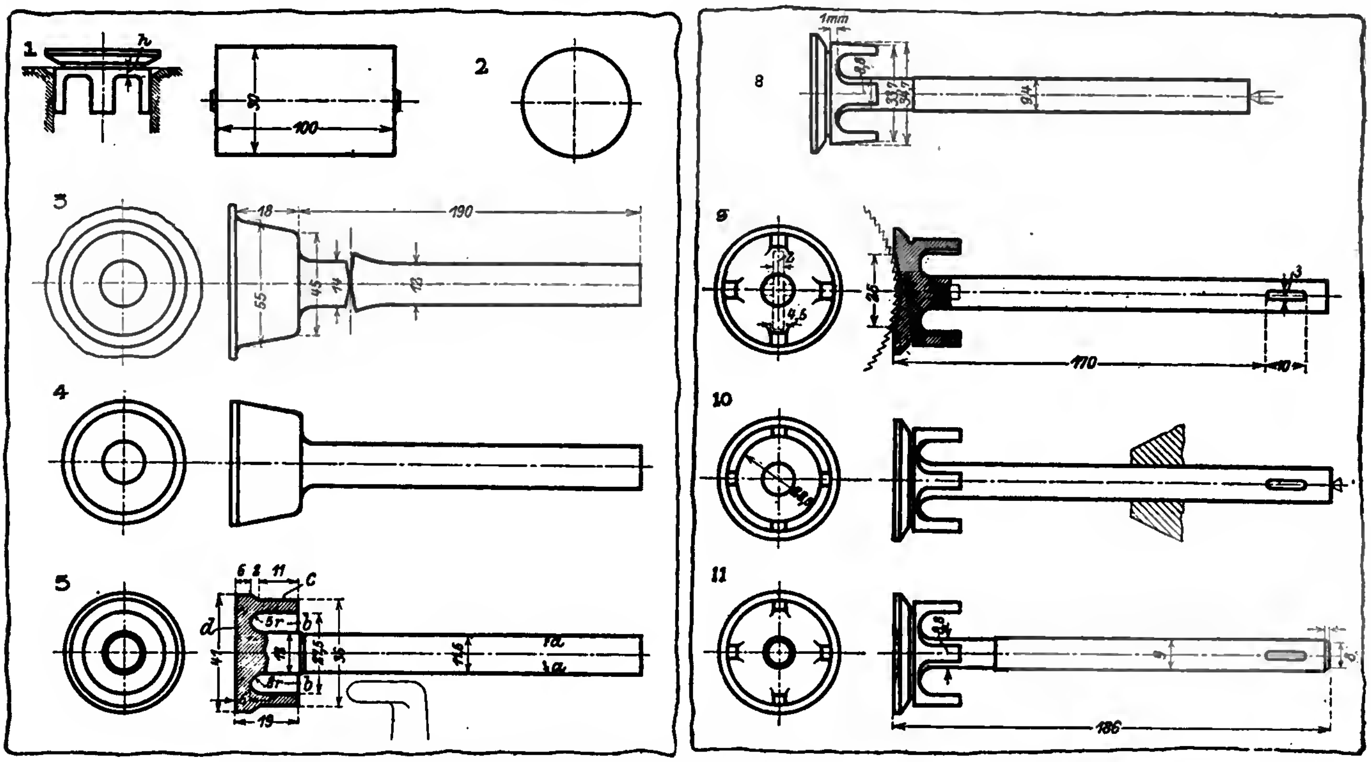


Figs. 6 and 7—An interesting stage in manufacture of Adler valve

It is often ascertained that a motor which does not knock when it is cold, does so when it is hot. In the first place, the pressures in the combustion chambers are usually higher when the motor is hot, but the principal reason is that many lubricating oils lose their vicosity at high temperatures. The film of oil then becomes incapable of resisting the shocks. Lubricants of poor quality are therefore a primary cause of knocking. The oil to be preferred is not the one which is thickest when cold but one which remain viscous when heated. From this point of view castor oil gives remarkable results. [Making it the favorite lubricant for aviation and racing motors, with regard to which it does not matter that the use of this oil necessitates the cleaning of the motor at frequent intervals.—Ed.]

When the play reaches several tenths of a millimeter probably not even the most consistent oil can prevent knocking, and the bearings should be worked over.

It is often found, however, that a motor knocks without any



Figs. 1-5 and 8-11—Type of double-closing poppet valve and progressive stages in the making of it appreciable play in the joints being traceable. The cause of the evil is then to be sought in the exaggerated pressures arising at the moment of an explosion; and this is by far the most prolific cause of the trouble. The lubricating oil, whatever its quality, always rises somewhat above the tops of the pistons and burns together with the fuel gases. If it burned completely there would be no trouble; on the contrary. But unfortunately the oil is decomposed before it burns, and this causes a fatty and carbonaceous coating to be deposited on the colder walls of the cylinders. The volume of the combustion chambers is reduced by this action. The compression ratio is increased. As the pressure created by an explosion is so much more powerful as the preceding compression has been higher, it can evidently reach a figure for which no provision has been made in the design of the connecting-rod bearings and becomes then in itself a sufficient cause by which knocking may be explained.

A motor of 80 bore and 150 stroke, in which the compression is normally 4.5 kilograms (per square centimeter), may be taken as an example. As the volume of one of the cylinders is about .750 liter, the volume of a compression chamber is found (according to the formula expressing the Mariotte law of inverse proportionality of volumes and pressure) from the equation

$$v = \frac{V}{p-1} = \frac{0.750}{3.5} = 0.210$$

to equal .210 liter. And the surface of the walls of such a compression chamber, including the top of the piston, measures at least 200 square centimeters [assuming the most favorable, semispherical shape of the chamber]. If it is now supposed that a layer of carbonaceous precipitate 1 millimeter in thickness has been deposited—which is not exaggerated but often realized in practice—the volume of the deposit aggregates 20 cubic centimeters, and the compression is raised, in accordance with the equation:

$$p = \frac{V+v}{v} = \frac{0.750+0.190}{0.190} = 5$$

to 5 kilograms.

This increase is more than sufficient for making a motor knock which has already run for some ten thousand kilometers, even if its shaft and connecting-rod bearings still appear to be properly adjusted.

The fouling has, besides, too often also another effect. The carbon particles, which are poor conductors of heat, remain incandescent after the explosion, notably in the vicinity of the exhaust valve. They may still be glowing when the piston compresses a fresh charge and may ignite this charge prematurely, thereby causing an energetic knock.

It is perceived from this survey of the factors involved that the gradual fouling of the motor should be attentively watched and, at the first sign of knocking, the trouble should be attributed to this cause rather than to loose bearings. It is easy to ascertain the condition of the compression chamber, if one is in doubt. It is sufficient to unscrew a valve plug and scratch off the black layer which covers the inside. Its thickness is an indication, but it should be remembered that the surface thus brought to light is one of the cleanest in the cylinder head, as it is swept by strong gas currents which counteract the formation of deposits. A much thicker layer will in each case be found on the top of the piston and the bottom of the combustion chamber. The motors with high compression now in use in which heavy fuels can be burned, thanks to their perfected carbureters, need cleaning for every 6,000 or 8,000 kilometers of travel. Formerly the process of cleaning was a serious affair at which one might well hesitate. Time was lost, the cost was high, and the fear that the motor might be remounted defectively was too often justified and made one postpone the operation as long as possible, but now, since it has become established practice to clean by means of oxygen—burning out the deposits—these fears and postponements are no longer in order. In a single hour the motor can be restored to its pristine perfection.—From *La Vie Automobile,* May 31.

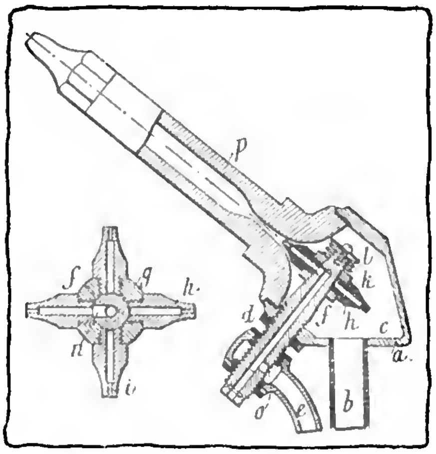


Fig. 12—Burner with variable oxygen feed, for autogenous welding

SUBSTITUTE for Acetone.—The importance of acetone for the automobile industry depends at present mainly upon two of its established properties. In the first place, acetone absorbs acetylene gas in very large quantities, holding the gas in a small volume as if it were strongly compressed and yet yields it up at a very low pressure suitable for the feeding of acetylene lamps and, for that matter, for acetylene motors, if any such were perfected. Secondly, acetone is a solvent for some of the components of lubricating oil, and it has been shown at the Prussian *Materialprüfungsamt* (Bureau for the Testing of Materials) that, when those components are removed from lubricating oil which are soluble in acetone, the remainder is refined and improved to such an extent that the exhaust gases of a motor in which it is used no longer emit nauseous odors.

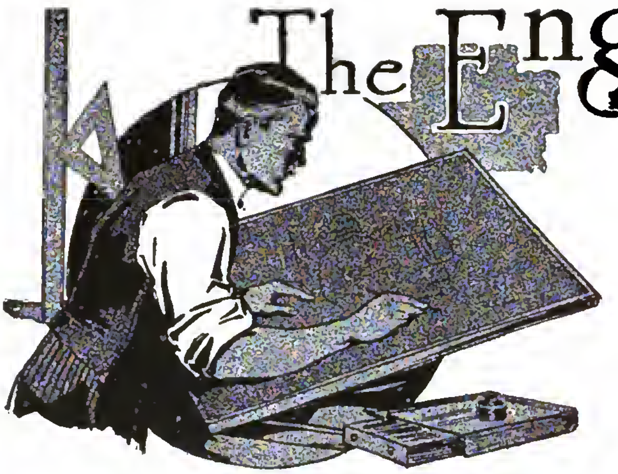
Only the cost of acetone has militated against the more extensive use of it for the refinement of oils and other purposes. Among the latter may be mentioned its application as a solvent for acetyl-cellulose in the manufacture of incombustible substitutes for celluloid, for which a market is also being created in the motor industries.

The announcement that a substitute for acetone has now been found which is offered for as low as 21 cents per kilogram, or about one-half of the price of true acetone, is therefore of considerable prospective interest. It is turned out at the Buckau chemical works at Magdeburg, Germany, and from the detailed description of its properties given in *La Technique Moderne* of June 1 it appears to possess all the qualities which eventually should make it valuable for the automobile purposes referred to.

OXY-ACETYLENE Burner with Variable Oxygen Feed.—It is in some cases useful to be able to modify the proportion of oxygen which is mixed with the acetylene gas in the oxy-acetylene burners used for the quick cutting of metals and for autogenous welding, as usually the modification is effected by means of a petcock placed in the oxygen conduit for this purpose. But this method has the fault of reducing the pressure required at the entrance to the mixing-chamber and therefore also the velocity of the jet which comes out of it. Fig. 12 represents a burner of new design in which this inconvenience is avoided by means of a multiple oxygen jet. The acetylene reaches the mixing chamber *c* of the burner *a* by way of conduit *b*, while the oxygen arrives through tube *e* which ends in a hollow piece *d* from which the cone *f* branches into the mixing-chamber. Upon this cone there is mounted the multiple jet composing a ring *g* (shown separately) in which are inserted the laterally flattened individual jets *h*. This multiple feed device is adjusted upon the cone *f* in such manner that the hole *n* in the latter registers with that one of the jets *h* which should communicate with the nozzle *p* of the burner whose walls it touches: it is held in place by the washer *l* and a spring *k*.

The form of the jets *h* is such that they adjust themselves in the axis of the nozzle *p* automatically, and their flattened form leaves between them and the wall of the nozzle two orifices for the acetylene. As the jets differ in diameter the apparatus admits of modifying the composition of the gas mixture.—From *Maschinenkonstructeur,* April 3.

The Engineers' Forum



Defects in Springs

Never Finds Springs Too Long—Is an Auxiliary Shock-Preventer Necessary?

Downing Thinks Springs Need More Attention
La Porte Believes in Use of Shock Absorbers
Is Problem for Each Car Says Streit

BOTH engineers and readers are taking unusual interest in the discussion arising over the points brought out in the paper by Mr. G. H. Baillee entitled Defects in Springs, which appeared in THE AUTOMOBILE for May 29. Several communications have already been received, three of which follow:

Make All Springs Much Longer—E. Downing.

SAN FRANCISCO, CAL.—Editor THE AUTOMOBILE:—We agree with Mr. Baillee's article in THE AUTOMOBILE for May 29 in which he states that springs have apparently received less attention than any other part of the automobile.

We do a great deal of spring repairing, are said to have the most complete plant for the receiving of machines with broken springs and repairing of them.

As the cars come directly to our factory we have had the best of means to make a study of springs and their weakness in almost every make of car and to apply the same in the manufacture of our guaranteed spring. We find springs too light, too heavy, too short, **but never too long.**

With the carrying of the tires on the rear end of the cars another disturbing element has come into spring construction and from the amount of reconstruction we have done here on the springs of new cars the manufacturers have no doubt had the matter called to their attention long before this.—E. DOWNING, President, Hoover Spring Co.

Shock Preventer Is Necessary—LaPorte.

NEW YORK CITY—Editor THE AUTOMOBILE:—Referring to the article entitled Defects in Springs, published in THE AUTOMOBILE for May 29, we believe the author has discussed a subject which is demanding attention of all motorists as well as automobile manufacturers. As pointed out, the suspension system of the automobile has practically remained the same and has not kept pace with the improvements to other parts, so that with increased speeds, efficiency, endurance, power, we still get the bumps, shocks, and general racking caused by the inherent defects of spring suspension. However, it is not due to lack of attention to these parts that there have been no improvements, but to the fact that it is impossible to control the action of the springs without some auxiliary device.

It is evident that springs designed to permit easy riding over smooth pavements will jounce considerably over rougher roads and springs designed for cross-country roads will be entirely too stiff for smooth roads. It is also impossible to design springs that will be as flexible with one or two passengers as with five or seven people. In other words the difficulty in the problem of spring suspension was this: Stiff springs are not flexible enough to absorb comparatively small shocks. They cause considerable vibration of the car when a light load is carried, as their period of oscillation is short, which means that when compressed and released they vibrate rapidly and return to their normal position so quickly as to cause discomfort to the occupants of the car. Very limber springs, on the other hand, to go to the other extreme: When car is loaded or traveling over comparatively rough roads, they allow the body to bounce up and down, as they have a very slow rate of oscillation, also they permit the wheel to jump, thus inducing tire wear, and general chassis depreciation owing to the motor speeding up when the wheels leave the ground. Hence, the necessity of an auxiliary device or shock preventer to control the action of the springs.

So-called shock-absorbers and preventers that depend upon friction for resistance must by virtue of the principle upon which they operate give the same action regardless of road conditions, as they simply stiffen the springs. As pointed out in the article referred to, these devices soon lose their adjustment and are positively of no benefit, but act as a dead weight, therefore our shock preventer has been designed on an entirely different principle. It consists of a series of inclined planes and expanding and contracting disks of firm but resilient rubber which work on the wedge principle. It is not friction but graduated compression of rubber by thoroughly lubricated inclined planes. These planes ride up on each other according to road conditions. Instead of flying back to its normal position the resistance controls the action of the spring, bringing it back to its normal position gradually and preventing the usual jolt and excessive vibration.—CHARLES LA PORTE, Engineer, The Aristos Co.

Commercial Side Rules at Present—Streit.

SEATTLE, WASH.—Editor THE AUTOMOBILE:—Mr. Baillee's remarks sound very well but I fail to see very much in the subject, as he has treated it. It is admitted by all, that automobile manufacturers have not given the attention to the spring suspension which is necessary to a perfect car, but I question whether this matter can be determined on the lines mentioned by Mr. Baillee. It is an admitted fact that none but the high-grade, double-heat-treated spring is suitable for automobile service but this is a matter which must be worked out by the purchasing agent, engineers and spring manufacturers. The hardest proposition, is to induce the purchasing agent to pay the price that will justify the spring maker furnishing a thoroughly dependable spring. If this obstacle can be overcome the road is an easy one, as between the engineer and the spring manufacturer there is no trouble in arriving at a proper grading to carry the passenger comfortably and when this has been determined the tires have secured all of the relief that the spring constructor can afford them. In other words when you have made a spring that will carry the passenger as comfortably as he is entitled to be carried, your springs cannot be made to afford any additional relief to the tires. The spring suspension is a matter which cannot be worked out as applied to automobiles in general, but must be determined for each particular make and model as no two machines that we know of are precisely alike in their weights.—W. E. STREIT.

Sales Department Influences Car Design

From the Paper Read Before the S.A.E. and I.A.E. Visitors by F. E. Moscovics

F. E. MOSKOVICS' offering to the society of a timely paper on the relations between the sales and engineering departments of the motor car factory was productive of a large amount of interesting discussion among the members. The further unity of these departments and better co-operation was advocated. Excerpts from the paper follow:

A few years ago the design of motor cars was practically dictated by the sales department, the engineering department being merely a way station to put the views of the sales department into such technical form as would enable the factory to manufacture a car therefrom. This was due chiefly to the embryonic condition of the industry and also to the fact that substantially all the real executives and heads of factories were themselves salesmen, as well as to the fact that there was no intelligent public demand. The motor car was new; the man in the street did not know what he wanted; horsepower varied from 4 to 120; gearboxes from belt to direct drive. Technical knowledge was as yet unmated with experience—so, naturally, the views and influence of the sales department was dominant and supreme.

Then, a few cars appeared, which due to their great mechanical advances, made a profound impression on the public. The design of these cars was actuated solely and purely by experience; the result was Renault, with light weight and shaft drive; Mercedes, with selective transmission, mechanical valves, cellular radiator, etc. Coincident with the arrival of these cars appeared the awakening of public demand, and, whereas the early engineer taught the public what it ought to have, today the public is surely telling the engineer and manufacturer what it wishes to have, in no silent voice.

About this time the influence of the sales department in the matter of design began to wane a little, in a large degree from the fact that any car on four wheels would sell. It was not so much a matter of which car was best, as what car could be delivered. Now, if we can assume that the day has passed when a customer considers himself fortunate if he can obtain an early delivery; if we take for granted the absolute necessity for stronger-basic work (sound financing, good engineering, efficient production and economic and effective selling); if we can thoroughly grasp the why and wherefore of inter-department economies, and the need of inter-departmental coöperation, and, with these things in mind, grant the advantages that may be attained, we can approach the subject of this paper from a more intelligent angle.

Purpose of Paper

It is not the purpose to attempt to lay down rules or theories of salesmanship except insofar as they affect the relations of the sales department with the engineering department, and the influence that the sales department may bring to bear on the engineering department. In considering the subject certain definite conclusions must be assumed: What is the object of the organization as a whole? Is it to make the greatest mechanical success, regardless of financial results, or to make the greatest financial success—to pay big dividends? Taking the latter as the most logical and sought-for result, obviously, that relationship of the two departments which will tend to create the greatest efficiency of each and of both as a unit is the desirable and ideal. Obviously, again, the greatest car in the world, from a mechanical standpoint, could not be marketed without a sales organization or sales channel of some sort to present it to the prospective buyer nor could the greatest selling organization under Heaven make a permanent selling success of a thoroughly poor and badly engineered car. Accepting this conclusion, then, let us approach the subject from the viewpoint that each department is dependent for sustenance and success on the other, and that each is quite useless without the other, and that the ideal condition is obtained by taking the best ideas of each and molding them to the greatest mutual advantage. If the sales department were fitted and trained to authoritatively inform the engineering department what the trend of the public demand evinced; if the engineering department were, by virtue of its confidence in the views of the sales department, in the receptive frame of mind essential to the acceptance of these views; and if the blended opinion of these two departments fitted in with the production standard that their particular organization was best fitted to handle, would not this nearly approach the ideal?

Co-operation

In many organizations the sales department wears a halo unwarranted by facts, and bad in principle. This is due to many causes, the main one being that it actually brings in the dollars; it is apparently the department that creates the much-sought dividends. Besides it is the department that comes into contact and mixes with the outside world to the greatest extent. It is, or should be, better fitted to tell of its own importance and greatness than any other arm of the business; its business is the art of selling, and it can, or should be able to, sell itself as well as it praises and sells the product at its disposal. In other words, the sales department is the mouthpiece of the organization, the real point of contact between that final judge, the ultimate consumer, and the factory. Naturally, this condition ofttimes becomes galling, especially to one so little given to the study of environment as the average motor car engineer. The result is lack of regard for the ideas, views and opinions of one department for the other. Of course, no lasting benefit can come from such a relationship. Each department has its functions; each is all-important to the success of the other. Healthy and deep respect for each other's views in everything that pertains to the welfare of the organization as a whole is requisite to permanent success.

In the past the average sales department has had little real knowledge of the art of motor car building; what it gleaned was of a purely superficial and perfunctory character, usually limited to a parrot-like repetition of a few technical platitudes called for want of a better name "talking points." No systematic attempt was made to thoroughly ground the salesman in the rudiments of the profession, nor did he, for lack of initiative and time, obtain the information on his own account. How few salesmen of even today have a real general knowledge of the basic facts of the business. They have been, and to some extent are still chosen for their appearance, glibness of tongue, and

F. E. Moscovics, who presented the important paper on the influence of the sales department on car design personality, rather than with due regard to the adaptability to learn, digest and transmit knowledge in a clean-cut manner.

The day is, however, rapidly approaching, if indeed it is not already upon us, when motor cars must be sold and not bought. The buying public become car-wise and knowing what it wants has little respect for or patience with the man who cannot explain in a clear, concise and logical manner the different points of a car that may come up for discussion. The man buying his second or third car has well-defined ideas of his own, and cannot be talked into an unwise investment, nor influenced by mere talking points. The points must be real points, and be well presented. The public craves information in a rational form. The time has passed when anything less will do. This is a day of facts, not fancies. The merely magnetic talker has seen his day.

As illustrating the kind of salesman who cannot succeed today, the following story of a few years ago will perhaps suffice: Jones, the star salesman of a prominent foreign car, was asked by a prospective buyer what form of ignition was used on his car. "Low-tension make-and-break," he responded. "What is the difference between low-tension make-and-break and high tension?" the customer inquired. Jones was momentarily nonplussed (here was a point that his motoring education had not covered), but only for an instant. "Are you an electrical engineer?" he asked. "No, I can't say that I am," Mr. Buyer replied. "Then, really it would be quite useless for me to attempt to explain it to you," said Jones. When Jones told me the story to show how clever he was, I asked him what he would have said if the prospect had said that he *was* an electrical engineer. "Why," said Jones, "I would have told him, 'Then you ought to know more about it than I do.'"

Salesman Must Know

The day of Jones is coming to an end. Naturally, an engineer, who has been brought up on facts, whose entire make-up should be to take nothing for granted, who wants reason (even to an unreasonable degree) for each change of design or model, whose education and training from the university to the factory has been to accept only laws—not fallacies—is not readily impressed by the desire or opinions of sales departments of the type indicated. He feels immediately, and often correctly, that demands born of such scant knowledge are mere shams to cover up its own weakness and an attempt to shunt to his shoulders a responsibility which his own commercial instincts have not, except in a few rare instances, been developed to bear. If, however, backed up by the chief executive he carries his views and ideas, to the exclusion of the other department, he assumes an enormous responsibility, and only discord can result. If, to support his position, he cites his own experience and quotes from the statements of the few users of his product with whom he has come in personal contact, he is treading on very thin ice, indeed. Right here is the pitfall that lures many engineers. They accept too blindly the result of a few experiments or the words of a few persons. What is needed to intelligently guide them is enormous road experience and a knowledge of the demands of hundreds of people. In other words, the average engineer is too provincial and self-satisfied with his work to be in a position to judge what is the desirable and correct design of the future. Is it then any wonder that we see so many cars whose appearance is far below standard?

The blame for this condition should, however, not be charged to the engineer so much as to the executive, who usually loads the engineer down with a mass of work not rightfully within his province. How many engineers are doing the work of chief inspectors, assisting in the purchasing, service and production departments? Few factories provide the engineering department with adequate help of caliber capable of handling properly the detail which the chief engineer feels must be watched by his department, the result, of course, being that the head of the engineering department, while thoroughly familiar with his own product and knowing in a general way the trend of the industry, simply has not the time to follow those niceties and refinements of design and beauty of detail in small things, which the foreign engineer is teaching us, and which are molding public opinion so strongly.

A Proposed Solution

Could the engineer have at his disposal the concrete views of a trained body of men; could these views be presented to him in time to reasonably allow him to get up new designs; could he be placed automatically in closer contact with the user of his car, is it not evident at a glance that enormous benefits and economies would result? It is clear that the economies so necessary to success in the industry today will not allow an organization to have a specially trained corps of men for this work. Where then should the engineering department get its closer contact with the public? Analysis points plainly to the fact that it is through the sales department. Moreover, the bringing of these departments into closer working relation should serve to raise the sales department to a higher standard of knowledge of its own products as well as of those of its competitors, thus enabling it to become more efficient in its own field and more capable of placing intelligently before the engineering department its views of future necessities of design, including comparison of the products of the particular organization and of competitors in actual service. In addition the sales department should grasp more understandingly the large problems of the production department, deterring it from making suggestions which on their face are out of accord with the policies or possibilities of the organization.

Closer Department Contact

Granted that an engineer has a clear-minded and well-trained sales organization to present his car to the public, one that he knows has a very good rudimentary knowledge of the profession, has he not, when it comes to forecasting the demand of the future, an enormous advantage over his brother, who is in constant discord and conflict with his sales department? Generally speaking, the design of a particular car is based on the theory and reason of the engineer. If he cannot impress those nearest to him with the correctness of his theory or the soundness of his reasoning, there must be fallacy somewhere in the organization. If the views of sales departments be subordinated, the chief executive will receive continually communications giving the best excuses in the world why the product is not selling. If it be the engineering department, either a twelfth-hour change is necessary, or, if the matter has been brought up in time, the engineer will be compelled to lay out something against his will and judgment. If, on the other hand, the points of contact between the two departments were such that during the period of inception of the car, the engineer were kept constantly advised of the views and ideas of the sales department, of the success of his product in the hands of the public, would not the resultant product be very much better? Would it not be easier for the sales department to market such a product enthusiastically? Would not the engineer be given confidence that he was building something that the public demanded, and that he was filling a long-felt want? Would not the sales department assist greatly the technical work of the engineer?

Summed up, the problem has two aspects:

First—In the majority of instances there are entirely insufficient points of contact between the sales department and the engineering department.

Second—There are insufficient points of contact between the engineering department and the ultimate user of its product.

How, then, to cure these apparent defects? Surely, an annual

T. C. Pullinger, who told of his experiences in Scotland in the discussion of Mr. Moscovics' paper meeting where all the salesmen are brought together in a joy-feast is not the place; the chief engineer, let us say, addresses the body; as a whole, the members are known to be gathered merely for the purpose of mutual admiration. The average house organ is not the medium, because truths are not told there; the house organ is usually a means of self-praise rather than self-analysis.

In this paper no consideration is given to the chief executive or the general manager as a factor for the reason that its object is to suggest an automatic means of communication of thoughts and ideas between the two arms of the business, and naturally the supposed superior knowledge of the head of the organization will be superimposed on the hoped-for result of the closer union of these two departments. As there appears to be at present no definite channel through which the two departments can come more closely together, the writer suggests:

First—A weekly engineering bulletin, edited by the chief engineer, taking up in groups the different parts of the vehicle, preferably employing the same nomenclature the factory has given to the various parts, appending the part or piece numbers in question (this will familiarize the salesman with part numbers).

Care Must Be Exercised

Pains should be taken that the bulletin be free from abstruse technical terms and data which might not be easily digested. Care should be taken to inquire whether the salesmen can read simple blueprints; if so, diagrams explaining the theory of the various points should be furnished. The salesman would thus obtain a direct knowledge of the product which he could gain in no other way. In each bulletin a personal appeal should be made to the salesman that he request any information on any point that he does not understand thoroughly, and a further explanation should be cheerfully and gladly given to him. The chief of his department should constantly urge him to correspond directly with the chief engineer on these points, and it should be strongly impressed on his mind that it is no disgrace to come back and say that he does not understand the topic discussed in a certain bulletin. In fact, the writer would urge that upon publication of the bulletin it become mandatory on the part of the salesman to express weekly his view on the topic described.

Although it is argued that the chief engineer be the editor of the bulletin, it is, of course, not necessary that he do the actual work in connection with it. He can lay out topics to be covered, and have his assistant or any other capable person collaborate with him. It is, however, the business of the engineer, to see that the bulletin actually reflects his views and ideas, the object being that the spirit of the organization be built around the chief engineer's conception and theory of the product. He need never be at loss for a topic. If in say twenty weeks he has covered the general points of design, he may then deal with such subjects as economy of fuel, the best means of caring for the clutch, the motor starter, etc. The accessory firms alone could furnish enough data to keep such a bulletin alive for a very long time.

With regard to my second suggestion, contact between the engineer and the owner, the problem is somewhat more simple. The appended form could be sent to every agent and distributor of the factory, with positive instructions that it must be filled out every sixty days. This would give the engineer first-hand information as to exactly how the product is being received. It would enable him to eliminate apparent defects due to local conditions. Let us assume that from the replies it becomes evident that there is considerable noise in the shifting of gears. It is not supposed that the average agent will be able to analyze the clutch problem; that he can tell whether the clutch is too heavy or the gear ratios incorrect. That, of course, remains for the engineer to diagnose. But the replies will place in your hands, without delay, troubles resultant upon design or manufacturing defects. Again, let us assume that the gasoline and oil consumption are very high, much higher than you know should he the case; the service department will instantly get into communication with the dealer and help him to alleviate the condition.

Of course, the theories advanced here, like all theories, are useless, if not used. The object of this article is to point out a means whereby the influence of the sales department on the engineering department can be brought to a stage of intelligent coöperation.

Form for Engineers' Use

It is highly important for your own benefit as well as ours that you give us the following information as accurately as possible. It is our endeavor to make our cars meet the severest general requirements and only by a definite, direct and accurate knowledge of how they act under widely varying conditions can we hope to accomplish this. Please be guided accordingly:

Date:
Agent's name:
Name of territory covered by your company:
How many of our cars are in operation in your territory?
What is mean altitude of territory covered by you?
What is general topography of territory covered by you?
Mountainous
Hilly
Level
Are road conditions good?
If not, please briefly state conditions and about what proportion of roads are macadamized, etc.
What is maximum average temperature?
What is minimum average temperature?

1. Does our line have power enough for your customers? If not, what would you suggest?
2. Is our motor quiet enough for your clientele?
3. Is our line flexible enough?
4. Do our motors accelerate rapidly enough?
5. How do we compare with competitors in our class? Please state which competitors, if any, surpass us.
6. Is the fuel consumption (both oil and gasoline) satisfactory? Please state your experience generally.
7. Are our gears quiet enough for your clients? If not, please state which are noisy.
8. Is the clutch action satisfactory, both as to engagement and holding?
9. Does our spring suspension meet with general approval?
10. Is our steering gear meeting all requirements?
11. Are our gear ratios correct for your territory?
12. Have you heard any criticism of our upholstery, either in material or workmanship?
13. Have you heard any complaint on the accessories we use? If so, please particularize.
14. Have you had any trouble reported on the bearings we use?
15. Is our rear axle construction meeting the requirements of your trade?
16. Please state any general criticism on appearance or general design you may have encountered.

This information is so important to us that we urge it be made out under the direct supervision and he signed by the head of your organization. It will materially help us build better cars.

Marmon Opens Discussion

President Marmon stated that the average engineer is too apt to design a car after his own tastes and in accordance with his ideas of what he would like to ride in.

G. W. Bennett, Willys-Overland Co., said that he has all along advocated a closer relation between the two branches of the business of making motor cars. Antagonism is often found but this is gradually being outlived, a better understanding generally taking its place. The salesman is the connecting link between the factory and the buyer. He teaches the owner and in this way sets the trend of design. Thus, a great influence is wielded by the sales force. If the engineering side will listen to the advice of the sales as to what the future design is to be, the former will get some valuable hints.

J. G. Vincent, of the Packard company, believes that he gets along with his sales department quite well. The engineer will not have any trouble if he is broad minded and always sticks close to the sales and, he believes, it is up to the engineering department to always take carefully the suggestions tendered by the sales department and to analyze these frankly, although, of course, the engineering end must not be swayed too far by these suggestions.

T. C. Pullinger, a leading Scotch maker and a member of the council I. A. E., has also had his troubles in getting the sales and engineering departments to act in harmony. Familiarity breeds contempt, and thus neither department takes much stock in what the other says. The plan adopted by his concern is to get the dealers and agents to meet at the factory and to confer with the organization at regular intervals. The engineering department takes a lot more notice of what these visitors say than they do of what the sales force says.

Once a year Mr. Pullinger's company calls a convention of this kind far enough ahead to give the designers plenty of time to incorporate any valuable suggestion in their new cars. Even earlier than this general dealers' convention, some of the principal dealers come and offer their ideas. These are incorporated in sample cars, which are later shown at the regular dealers' meeting, giving them something concrete to work upon and to criticize.

G. W. Dunham, consulting engineer, Chalmers, outlined the method employed by this Detroit concern in designing according to the public demand. This public "*wants what it wants when it wants it,*" he said. To keep closely in touch with the demands, the engineering department is continually asking for criticisms and suggestions from the dealers. To prevent the dealers from writing lengthy letters expressing their views, the company has provided printed forms in pads which may conveniently be placed upon the dealers' desks. They write on these their ideas and send them in along with other communications for the factory, thus doing away with useless words, and saving the designers' time in perusing them.

Besides this, about ten of the largest dealers send in daily reports of all repairs on the cars coming to their shops each day. If the engineering department receives reports of the same defect from several sources, it immediately investigates the breakage, thus being soon aware of any weak part. In this way the engineering department really works in the field itself, said Mr. Dunham. Circular letters are sent out from time to time to the dealers asking for their opinions as to future design and so on.

Mr. Dunham spoke of a mechanics' convention which his factory held. The men were sent from the various dealers' garages in small groups. Meetings were held dealing with all chassis parts and the men were asked for suggestions as to better ways of designing the various parts and were told why certain features were designed as they were. In this way a closer feeling of working together was engendered tending to make the men more interested in the factory's product.

F. P. Nehrhas, American Locomotive Co., advocated the closer relationship of all departments, also. He stated that his company has recently held conventions similar to those outlined by Mr. Dunham, from which great benefit to all concerned was derived. Though Mr. Moskovics' paper was a very full treatment of the subject, Mr. Nehrhas believes that he has touched upon only a small part of a very large subject.

Among the New Books

Works on Iron Analysis, Syndicalism, Automobile Troubles and Their Remedy and Coal Are Among Offerings

Exporters' Encyclopedia Gives Information on All Details Involved in Exporting Goods to Foreign Lands

THERE are many new books coming from the press this spring which are of interest to the automobilist, the manufacturer and dealer, and, indirectly, to all those affiliated in one way or another with the great and growing army of motorists in the United States. The works reviewed in THE AUTOMOBILE this week are of diversified character, the only one directly interesting to the automobile owner being that on Car Troubles, although the treatises on metals and coal will appeal to many and those on syndicalism and exporting are sure to find manifold uses.

METHODS OF IRON ANALYSIS. By Francis C. Philips. Published by the Chemical Publishing Co., Easton, Pa., 170, 9 by 5.5 inch pages. Boards, price, $1.

The methods employed in the laboratories of the different steel works vary to some extent. In view of this fact the methods in use in the iron and steel laboratories around the regions of Pittsburgh, Pa., were collected and published by the Engineers' Society of western Pennsylvania during the year of 1896. The demand for copies of this paper were such that the supply was soon exhausted, and by a resolution of the Society passed in 1897 it was suggested that the transactions be published and bound in permanent form. In this work are collected the methods of analysis used in each of the laboratories around the Pittsburgh region. The principal experiments are for the determination of the presence of silica, iron, manganese, aluminum oxide, phosphorus, sulphur, etc., in ores and in blast furnace cinders. Exact directions are given for the making of each specific analysis. For the iron and steel laboratory the work of this nature is practically indispensable.

THE IRONMONGER METAL YEAR-BOOK FOR 1913. Published by *The Ironmonger,* London, England, in note book style, 104, 3.7 by 6.3 inch pages. Boards, 2 shillings, 6 pence.

For 7 years the *Ironmonger* has been publishing this annual review of the metal market. The most valuable information that this work contains is the record of the price changes in metal during the year 1912. The closing prices for copper, tin, lead, spelter, pig iron, finished iron, steel, etc., for every day of the year of 1912 is furnished in tabular form. The imports and exports of the principal raw metals are also noted.

AMERICAN SOCIETY FOR TESTING MATERIALS TRANSACTIONS in four languages: English, German, French and Spanish. Full transactions of the 1912 meeting, published by the Society at the office of the secretary, University of Pennsylvania, Philadelphia, Pa.

Standard specifications for Bessemer steel wheels, open-hearth girder and high T-rails, bridge steel, building steel, ship steel, boiler and fire box steel, axle steel, carbon steel, for wheels, castings and forgings are given in these transactions together with notes on workmanship in these transactions which are complete in all four languages.

SYNDICALISM. By J. Ramsay MacDonald. Published by the Open Court Publishing Co., Chicago, Ill. 74 pages, printed on deckel-edge paper. Cloth, 60 cents.

A clearly-put exposition of syndicalism, based upon six articles appearing in the *Daily Chronicle.* This book should be read by all students of labor conditions. Syndicalism is organized unionism, its object being the uplift of the workingman by means of arbitration and the strike, on one hand, and by thorough organization on the other. It is non-political and, although some of its principles are the same, it differs from socialism. As the author states, "Socialism asks that economic power should be put in the hands of the community. Syndicalism asks that each industrial group of workers should control the instruments of production which it uses—the railwaymen, railways; the miners, the mines, and so on." As may be gathered from the work it should not be necessary to so clearly define the program of syndicalism, but, to again quote the author, "* * * the geese, having become so familiar with the 'Boo' of socialism that they are beginning to cease to waddle about when it is shouted in their ears, or being frightened out of their lives by the new 'Boo' of syndicalism." On the whole, it is a book worthy of careful perusal.

EXPORTERS' ENCYCLOPEDIA, 1913 edition, published by Exporters' Encyclopedia Co.. New York City. 1024, 5 by 8-inch pages. Cloth, $7.50, including monthly corrections and the *Exporters' Review* for the calendar year.

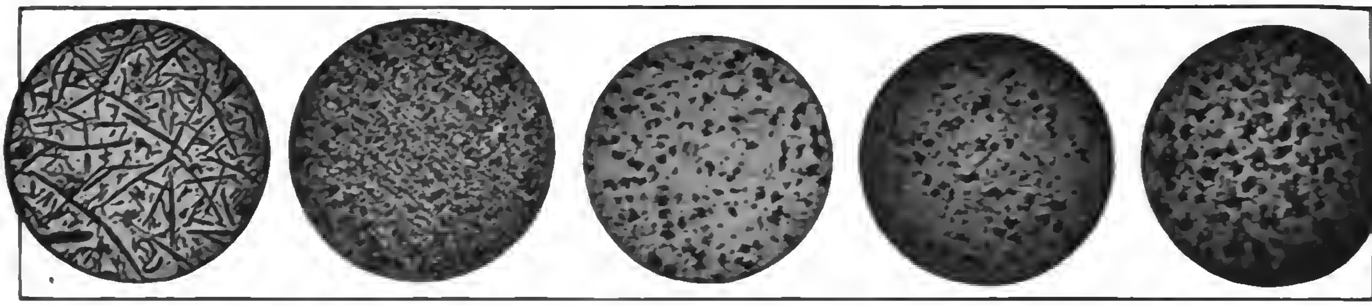
If you export goods to any foreign country and are not positively familiar with the methods of shipping, a work of this kind will be invaluable. The object of the book is to enable anyone to make a shipment to any foreign country in full security against delays, fines, etc. It tells the nearest and cheapest route, the consular regulations which have to be observed and the exact cost of same and also tells what the transportation companies require in the way of bills of lading, payment of freight, etc. When any regulations or prepayments are necessary it tells how to go about making them and in other words it acts as a standard reference work for the purpose of answering any exporter's or importer's questions.

CAR TROUBLES—THEIR SYMPTOMS AND THEIR CURE. By Harold Whiting Slauson, M. E., published by Harper and Bros., New York City. Fifteen 3.75 by 6.75-inch pages. Cloth, 25 cents.

Providing the driver knows where to look for the trouble in a general way this little book should be able to complete his investigation for him. The troubles are arranged alphabetically under the heads of clutch, engine, fuel, ignition, and cooling. If there is a knock in your motor and you know it comes from the cooling system you would be able to find it by looking under the latter head. But if you thought the knock came from a bearing, the location could not be found from the book. However, if there is any indication as to the location of the trouble the exact cause can be found by its aid.

COAL, by Francis H. Wilson, M. Inst. M. E., editor of *Mining Engineering,* published by Sir Isaac Pitman & Sons, London and New York, 129 4.5 by 7 inch pages, with half-tone illustrations. Cloth, 75 cents.

The coal resources of England are carefully studied and analyzed in this little volume. In England more than 1,000,000 people are employed in the coal industry alone. The author deals with the formation and the history of the coal seams, the method of working them, the surface arrangements of the mine and a study of the coal industry. The opening chapter of the work tells of the formation of coal through the decay of vegetation. A thin slice of coal examined under a powerful microscope will often reveal distinct traces of woody tissue and bark. The two theories of how the coal seams happen to form, whether by drift or in situ are expounded. All the varieties of coal are not listed but the different classes of coal are carefully studied. The increase in the economical use of coal is an important feature which the author studies, especially insofar as the use of the coal by-products is concerned. About 35,000,000 tons of coal are consumed every year for domestic purposes and the author quotes Sir W. Ramsay, who states: "We are still utterly wasteful in our consumption of fuel in domestic fires." The book is not too technically written and will make excellent reading for anyone interested in this industry.



Left to right: Fig. 1—Polished section of pig iron. Fig. 2—Polished section of white iron. Figs. 3, 4 and 5—Polished sections of annealed malleable iron

The Use of Malleable Iron for Castings

From the Paper Read Before the S.A.E. and I.A.E. by Enrique Touceda

ALTHOUGH malleable iron, as compared with steel, enters into automobile construction to a limited extent only, the actual amount used in the industry is large. **I believe it will be admitted as a general proposition that the constructing engineer, while very thoroughly posted on carbon and alloy steels, knows less about this material than possibly any other passing through his hands.**

There is a widely prevalent misconception that when any part of a malleable casting exceeds ⅜-inch in thickness of section, the change that normally takes place during the annealing process, whereby the hard and brittle white iron castings that come from the air furnace are converted into soft, tough and ductile ones, is but imperfectly accomplished.

The malleable iron process is conducted in two steps, the first of which consists of melting gray pig iron upon the hearth of an air furnace, when a certain amount of the original silicon, carbon and manganese is oxidized, and thus removed from the iron while it is being melted and subsequently raised high enough in temperature to successfully run the castings. The following three facts are well known to those who possess even an elementary knowledge of the metallurgy of iron and steel:

First, most of the carbon content of gray pig iron exists in the form of graphite; that is, free; if a pig be broken and the fractured end be gone over with a stiff brush, it is easy to thus remove the exposed little flakes of graphite held in mechanical mixture with the iron and always separated from the iron during and for an interval after solidification.

Second, when pig iron is uniformly white in fracture, no graphite is apparent upon inspection; instead of the carbon separating out in whole or in part as graphite, it is all combined with the iron **chemically.**

Treating Pig Iron

Third, a pig iron having most of its carbon in the form of graphite, can be changed into an iron in which none of its carbon will separate out as graphite if this pig iron be melted in such a manner that a certain amount of its silicon content be removed from it through oxidation; for silicon content in excess of a certain amount, prevents the carbon from combining mechanically with the iron; if it be removed gradually from a pig iron in which the carbon would normally have existed as graphite, a point will finally be reached at which its influence in forcing the carbon to separate out as graphite will cease.

It is an easy matter then to start with pig iron that is gray in fracture and in which all or most of the carbon exists as plates of free graphite, and end up with an iron that is white in fracture and in which all of the carbon is combined chemically with the iron; it is a question solely of getting rid of, in the air furnace, such an amount of silicon as will accomplish this end. It thus becomes obvious that the manufacturer of malleable iron castings, by means of his air furnace, experiences no difficulty whatever in converting gray pig iron into white cast iron; which operation constitutes essentially the first step of the process.

Many years ago it was discovered that if hard brittle white iron were surrounded tightly by an oxidizing packing, such as iron oxide in any form, and then raised to and maintained at a temperature of about 1500 degrees Fahrenheit for a few days, it would not only be changed into very soft and ductile iron, but some of its carbon would be removed during the interval. This constitutes the second step in the malleable iron process. Consequently, the first step toward getting soft and delicate castings in the malleable iron process, is to get very hard and very brittle castings, in which all of the carbon is combined chemically with the iron as carbide of iron, the very hardest constituent in either iron or steel. The second step is to break up this hard constituent into carbonless iron and free carbon, both of which are very soft. By the aid of photomicrographs what takes place during the second step of the process, that is, in the annealing ovens where the white and brittle castings are placed to be converted by time and temperature into finished castings, will be explained in a non-technical manner.

Fig. 1 illustrates a polished unetched section of a piece of gray pig iron, the object of which is to show the plates or flakes of graphite that separate from the metallic iron, when the silicon is sufficiently high in the iron to force the carbon thus to separate. It will be noticed that there is practically no regularity of either size or distribution of these flakes; therefore it is not to be wondered at that cast-iron test-bars show great irregularity in strength, even when poured from the same ladle of iron.

Fig. 2 shows a polished section of white iron, white because its silicon content was too low to force any of its carbon to separate out as graphite. The whole of the carbon consequently remains chemically combined with the metallic iron, invariably in the proportion of 6.67 per cent. carbon to 93.33 per cent. iron. This extremely hard carbide of iron is shown mostly in the white areas, but about 12 per cent. of the dark areas consists of this hard constituent also, the reason for which it is not necessary to consider for the purpose of this article.

As previously stated, carbide of iron is the very hardest constituent that can exist in either pig iron or steel, but fortunately, as already indicated, it has been discovered that if it be heated to about 1500 degrees Fahrenheit, for many hours, it can be split into little nodules of free carbon and a mass of practically pure iron, the former being very soft and having no strength, and the latter being both soft and very ductile and possessing high strength. An inspection of the polished sections of annealed malleable iron, Figs. 3, 4 and 5, will show that these little nodules of free carbon (the little

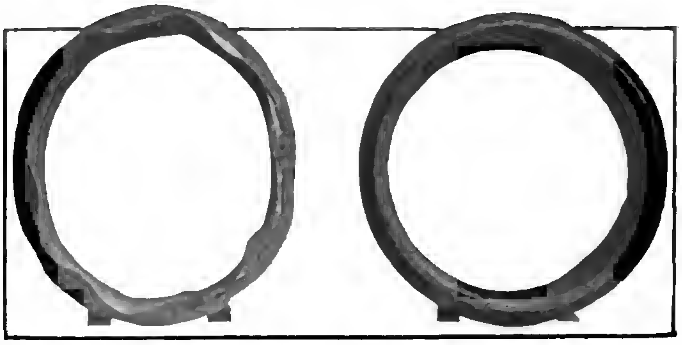


Fig. 6—Malleable iron clutch ring castings tested to prove that carbon particles do not injure the structure of the metal

black areas in the photomicrographs) are very uniformly distributed throughout the entire section and very uniform in size, differing in both particulars from the manner in which the graphite occurs in gray iron.

To contend that white iron castings over ⅜ inch in section cannot be annealed as efficiently as castings of less thickness, is to contend that a piece of white iron over ⅜ inch in section cannot be heated uniformly throughout its entire section to a temperature of 1500 degrees Fahrenheit or over. This is manifestly absurd, for it must be admitted that in many different processes very ponderous pieces of steel are being heated daily throughout their mass to any required temperature. The sole precaution in any case is to see that plenty of time be given the operation. As it happens that in the annealing process in the manufacture of malleable iron castings, some 7 days are consumed from the time the castings enter the ovens until they are withdrawn, if the breaking up of the hard carbide is not complete in the case of thick sections, this is certainly not due to lack of time to allow the piece to heat uniformly throughout. Moreover, there is no trouble whatever in maintaining the temperature of the ovens at any point under 1900 degrees Fahrenheit.

The direct question can now be put:

What is the limit of thickness of section beyond which white iron will not be efficiently and completely annealed; that is, not have all of the very hard constituent completely replaced by little nodules of free carbon and practically pure iron?

The answer is plain. Any thickness of white iron can be thoroughly and uniformly annealed throughout its section that is not so thick that it cannot be heated uniformly throughout, and in which the whole of its carbon content exists as carbide of iron. It has been shown that whether the carbon exists as carbide or as graphite, is simply a matter of how low or how high the silicon may be in the casting. It has also been shown that the adjustment of the silicon is under the complete control of the manufacturer. If the silicon is as low as 0.30 per cent. it is possible to obtain very easily sections as thick as 6 inches, in which all of the carbon will exist as carbide of iron, although in this extreme case, to break up all of the carbide and completely replace it with free carbon and iron, a higher temperature than that normally used during the anneal is required. In sections 3 inches thick, all the carbon will exist as carbide of iron when the silicon is around 0.50 per cent., in which event neither a higher temperature nor a longer anneal than is customary in ordinary practice will be required. I have therefore placed this as the limit of thickness for efficient and complete annealing. The trade, however, does not call for malleable iron in which the sections are this heavy. The statement can be made that if the process is fully understood by the manufacturer, and he will adjust the silicon content in accordance with the heaviness of the work, no trouble from this source should exist, and none ever will.

Referring again to Figs. 3, 4 and 5, I would explain that these photomicrographs were taken from an annealed malleable section 2 inches in diameter and several inches long. The sample was cast at my request from a heat in the regular course of work. While the company makes fairly heavy castings, none of the parts approaches this sample in thickness. Still, as will be seen, the silicon in their white iron was low enough to cause all of the carbon to form carbide of iron in a 2-inch round. This sample was annealed in the oven with their own castings in exact accordance with their regular practice. Fig. 3 was photographed at a spot about ⅛ inch from the surface; Fig. 4, at a spot midway between the surface and the center, and Fig. 5 directly at the center.

A close inspection and comparison of these three photographs should satisfy the most skeptical that this piece was

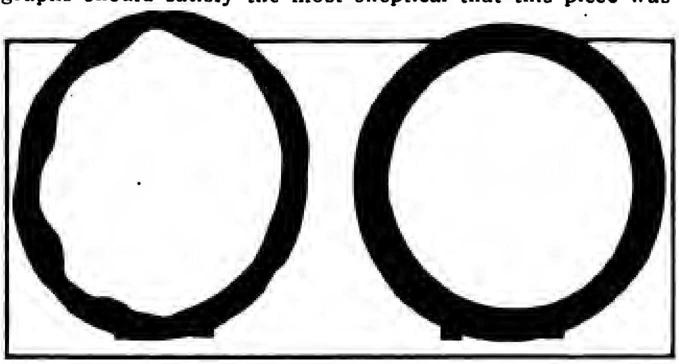

Fig. 7—Clutch ring casting after testing by machining down to ⅛ inch and subjecting to heavy blows with a hammer

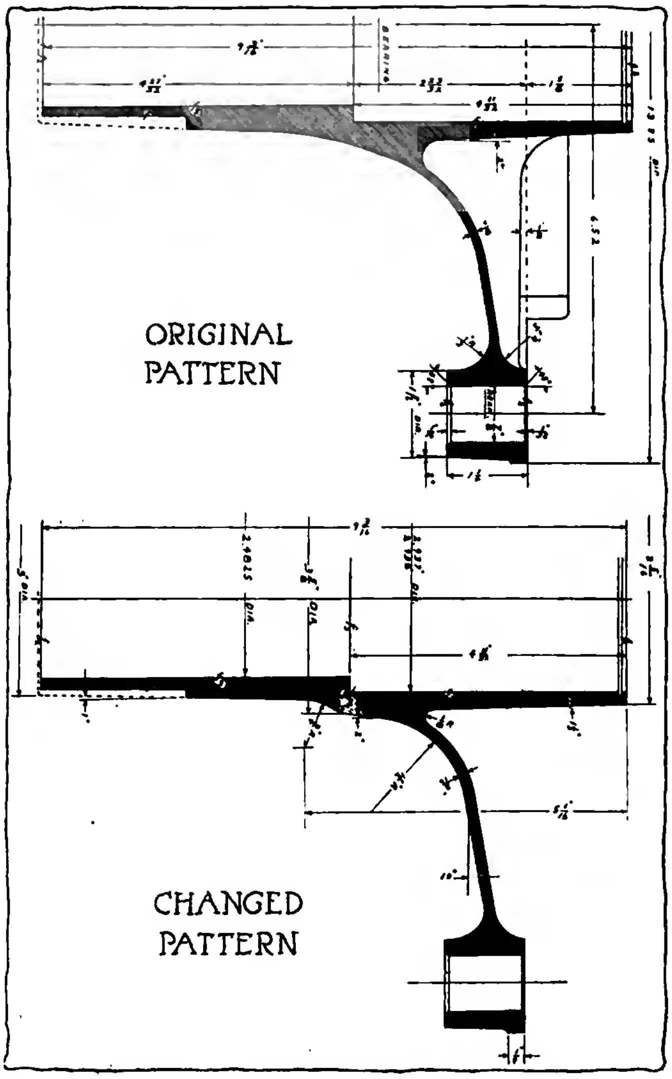

Fig. 8—The slight changes made in the pattern transformed the casting from a failure into a success

annealed with completeness throughout, and that all of the hard carbide was broken up into free carbon and soft iron. Accompanying this sample was another of 4 inches diameter, the central part of which I found contained considerable graphite in the form of flakes, which from their shape could be identified as having resulted from the separation of some of the carbon during the solidification of the white iron, showing that in this case the silicon in the normal mixture was not sufficiently low to have forced all of the carbon to combine with the iron, although had the silicon been somewhat lower, no difficulty in this particular would have been experienced.

Removing the Skin

In connection with the oft-repeated statement that if the skin of a malleable casting be removed, and the core tested, the latter will be found to be more or less worthless and that malleable castings are strong and ductile by virtue principally of the metal in the skin, there is no question whatever that the metal in the skin of well-made malleable iron is slightly superior to that which constitutes the main bulk of the casting, but only in the case of very poor malleable iron can a really great difference in strength between skin and core be noted; the poorer the malleable the more pronounced this difference. Malleable castings are not unique in this particular, for the metal in the skin of most steel castings is stronger than the central part of the casting, although not for the same reason that obtains in the case of malleable iron. The skin of malleable castings is practically decarbonized iron, the structure being uninterrupted by the presence of any little nodules of free carbon. The structure of the core, however, differs from that of the skin, only in that throughout it little nodules of free carbon are interspersed. That in good malleable iron these little particles of free carbon do not act in

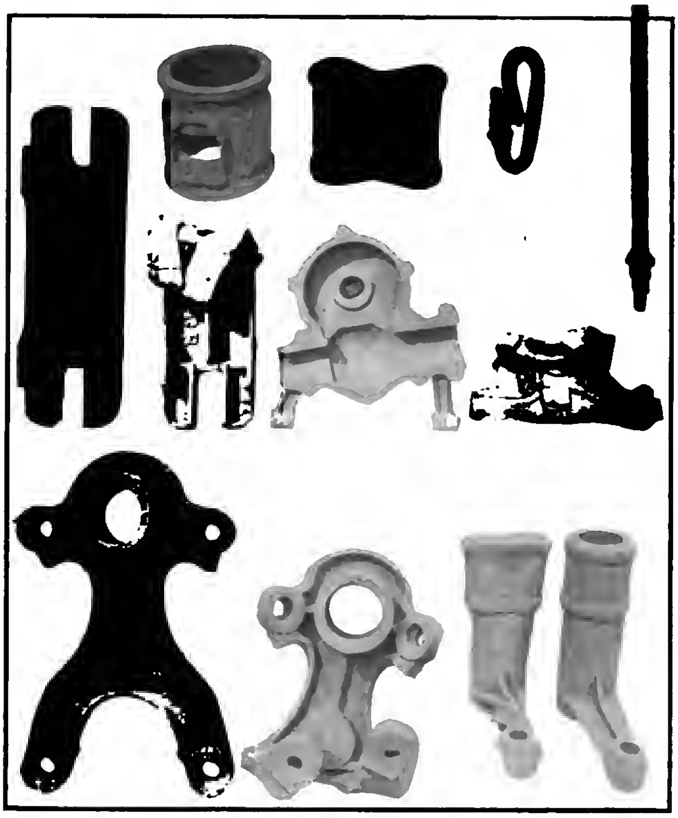

Fig. 11—Some castings which show signs of abuse

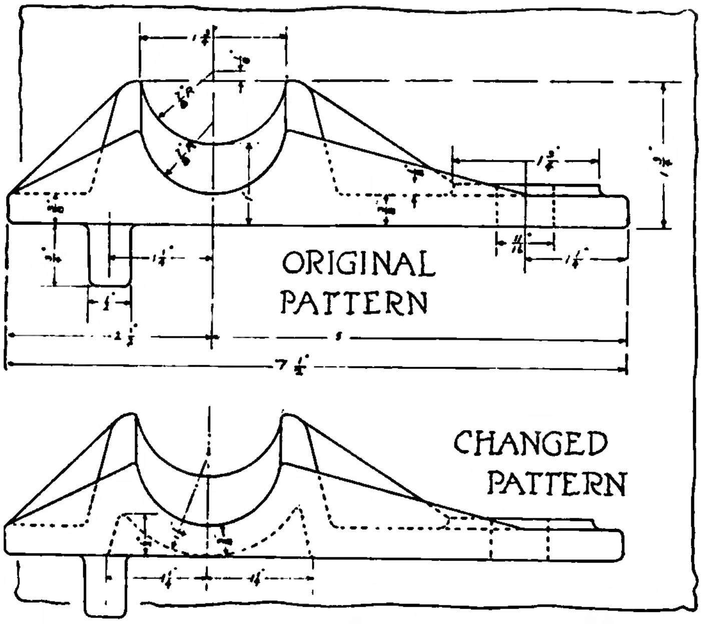

Fig. 9—The changes made in this pattern not only made a better casting but also reduced the amount of metal required

a way to injure the structure to any appreciable extent, I have satisfied myself by numerous tests conducted from time to time.

To illustrate this fact, I have secured two castings of an automobile clutch ring, Figs. 6 and 7. The 7/16 inch thick rim of the casting was machined down to a thickness of 1/8 inch, after which it was subjected to repeated heavy blows with a hammer to test the ductility and strength of the core left after machining. It will be seen that the metal of the core, in this instance, was of great strength and ductility, able to withstand great punishment without developing cracks of any magnitude. It is most likely true that the metal in the skin of this casting was slightly superior to that in the core, but I feel confident that the difference was not great, and I repeat that in good malleable castings, while the metal in the skin is a little superior to that of the core, the difference is but slight. The photographs referred to speak for themselves.

Status of the Industry

Some in the business have not kept pace with the advances made in malleable practice; some do not even understand the rationale of the process, or lack good manufacturing equipment. While fortunately these do not predominate, there are enough of them to throw much undeserved discredit on one of our large important growing industries. I am convinced, however, that the constructing engineer has, owing to improperly designed patterns, contributed unintentionally in numerous instances, to this situation. The worst offenders in this particular are the engineers for the railway car builders.

If the question of shrinkage and contraction be not properly considered, if the apportioning of thick to thin sections be not adjusted in accordance with correct principles, no matter how superior may be the metal *per se*, failure is the certain outcome. The remedy should be obvious. Practically all of the makers of malleable castings have on their staff men who are very proficient in the design of patterns from which to cast malleable. Much delay, much irritation, and a great deal of injustice will be eliminated, and a much stronger casting for the same weight of metal will often be produced, when closer relationship and co-operation exist between the engineer who designs a malleable part for any particular machine and the malleable pattern-maker at the foundry.

Lack of time has prevented my securing more glowing examples than the ones here shown, of how small need be the alteration in a pattern, in many instances, to produce good results where bad ones previously obtained. The changes shown in Fig. 8, although very slight indeed, made the difference between success and failure. The same remark holds good in the case of Fig. 9, the change producing not only a satisfactory casting, but one containing less metal. In connection with the center plate shown in Fig. 10, the following are the facts: Complaint was made by the railroad that these malleable castings were failing in service. The manufacturer of the castings made the request that he be permitted to alter the patterns in accordance with what his experience indicated would remedy the trouble. This privilege was not granted. The road then decided that malleable iron castings could not be depended upon in this particular case; so it was decided to have the castings made of steel. The steel men also objected to the design of the pattern, and, as almost always happens when a change is made from malleable iron to steel, were allowed not only the privilege denied before, but, as can be seen by reference to the drawing, were permitted to thicken the sections by one-quarter of an inch almost throughout. That changes were made in both design and weight is soon forgotten, but not that the steel casting stood up to the work and the malleable casting failed.

Physical Properties of Malleable Iron

As to the physical characteristics of malleable iron, I know that you are all familiar. However, at the end of this paper are reproduced some photographs of heavy malleable castings that you will acknowledge have been severely abused. They very eloquently illustrate the fact that when malleable castings are made by those who understand the process, castings that possess many valuable characteristics are produced. When toughness and ductility, ease of machining and low cost are considered, I do not know what metal can compete successfully with good malleable iron.

The tensile strength of good malleable iron will vary between about 38,000 to 56,000 pounds per square inch. When extreme ductility is desired, it is manifestly incompatible to specify high tensile strength. As in the case with carbon steel, so with malleable iron, ductility goes hand in hand with low ultimate strength; if high ultimate strength is desired, it can be obtained only by a sacrifice of ductility.

The elastic limit of good or of even indifferent malleable iron is equal to that of wrought iron and frequently exceeds it. When comparisons are made between this material and other metals, it would be more fair to consider the elastic limit rather than the ultimate strength, for it is the former upon which the engineer actually bases his calculations. The elongation and reduction of area of malleable are, of course, considerably less than of either wrought iron or soft steel. That both of these properties are high enough to impart great value to malleable castings is impressively attested by the photographs of the abused castings previously referred to.

It is the custom in plants of fair size to run various furnaces on mixtures for different classes of work. The mixture from one furnace is not as well adapted to one class of casting as to some other. If the user of the castings will only take the manufacturer into his confidence and explain the use to which any particular casting is to be put, the work expected of it in service, I know that loss of time will be avoided, and a more superior product had. Some consumers are under the false impression that for competitive reasons they should lighten their castings. This generally necessitates the introduction of more cores in the mold, the result being that the manufacturer is obliged to charge more per pound.

Specification for Malleable Iron

I presume that specification is of more interest to the membership than perhaps any other one question in connection with this material. I have no desire to usurp the duties of the committee having this matter in hand, the work of which in all that has been done has been so commendable, but a few words in connection with the S. A. E. malleable iron specification will I trust be taken in the spirit in which they are intended.* I believe that a mistake has been made in specifying an upper limit for silicon. As a matter of fact, it is well known that the higher the silicon in the white iron casting, provided the totality of the carbon in the casting exists in the state of carbide of iron, and all other conditions are correct, the better will be the finished product. I have shown that the manufacturer is obliged to eliminate his silicon to a point where all of the carbon will remain as carbide, and also that the extent to which he must carry out this elimination depends wholly upon the heaviness of the sections. It is exceedingly rare that he errs in getting the silicon too high, because he does not need a chemical analysis to safeguard this, as all that he has to do is to keep breaking his test sprue until he sees by the fracture that the iron is white, and that there are no particles of graphitic carbon in the fracture. He is more concerned in this particular than the purchaser can ever be, and to this extent the purchaser is protected. To specify an upper limit for silicon is about as necessary as to specify that the manufacturer shall pour his iron in the molds at a temperature sufficiently high to successfully run his castings. You can rest assured that he is going to look after the upper limit of silicon with as much fidelity as he will to be sure that the iron is hot enough to avoid trouble through misruns.

On the other hand, it would be wise to specify a limit beyond which the silicon shall not drop, because not only does the manufacturer err frequently in this direction in the making of black heart iron, but he is handicapped by having no reliable means of telling just when he is on the danger line. Analysis would take too long and the fracture gives no true indication. If the silicon is too low, a very inferior product will result, and still the purchaser if he be held to his specification can be forced to accept the castings.

The S. A. E. specification allows the manganese to be as high as 0.70 per cent. No one ever saw and no one ever will see black heart malleable iron of good quality with such a manganese content. Provided certain precautions are taken, and certain ratios made between certain elements in the product, it is possible to make a good product in which the manganese might be as high as 0.40 per cent., but to do so the manufacturer would have to be a master of his business and to know how to offset the evil effect of manganese on the structure.

Limit for Phosphorus

The upper limit for phosphorus given (0.20 per cent.) is all right, but it is actually the extreme upper limit that should be tolerated. The Society for Testing Materials allows 0.225 per cent. as an upper limit for phosphorus, but this is by far too high. I feel very confident that a good product could not be obtained if this limit were reached.

No mention is made in the S. A. E. specification as to carbon content, or the permissible amount of combined carbon tolerated; nor is any limit placed upon the allowable amount of total carbon.

Were not this paper already too long, I would like to make some comment upon the question of test bars for the determination of physical properties, etc. This can be taken up in a subsequent paper, if the matter proves of sufficient interest.

*The S. A. E. specifications for malleable iron are as follows:

Manganese	.30 to .79	Phosphorus	Not over .20
Silicon	not over 1.00	Sulphur	Not over .06

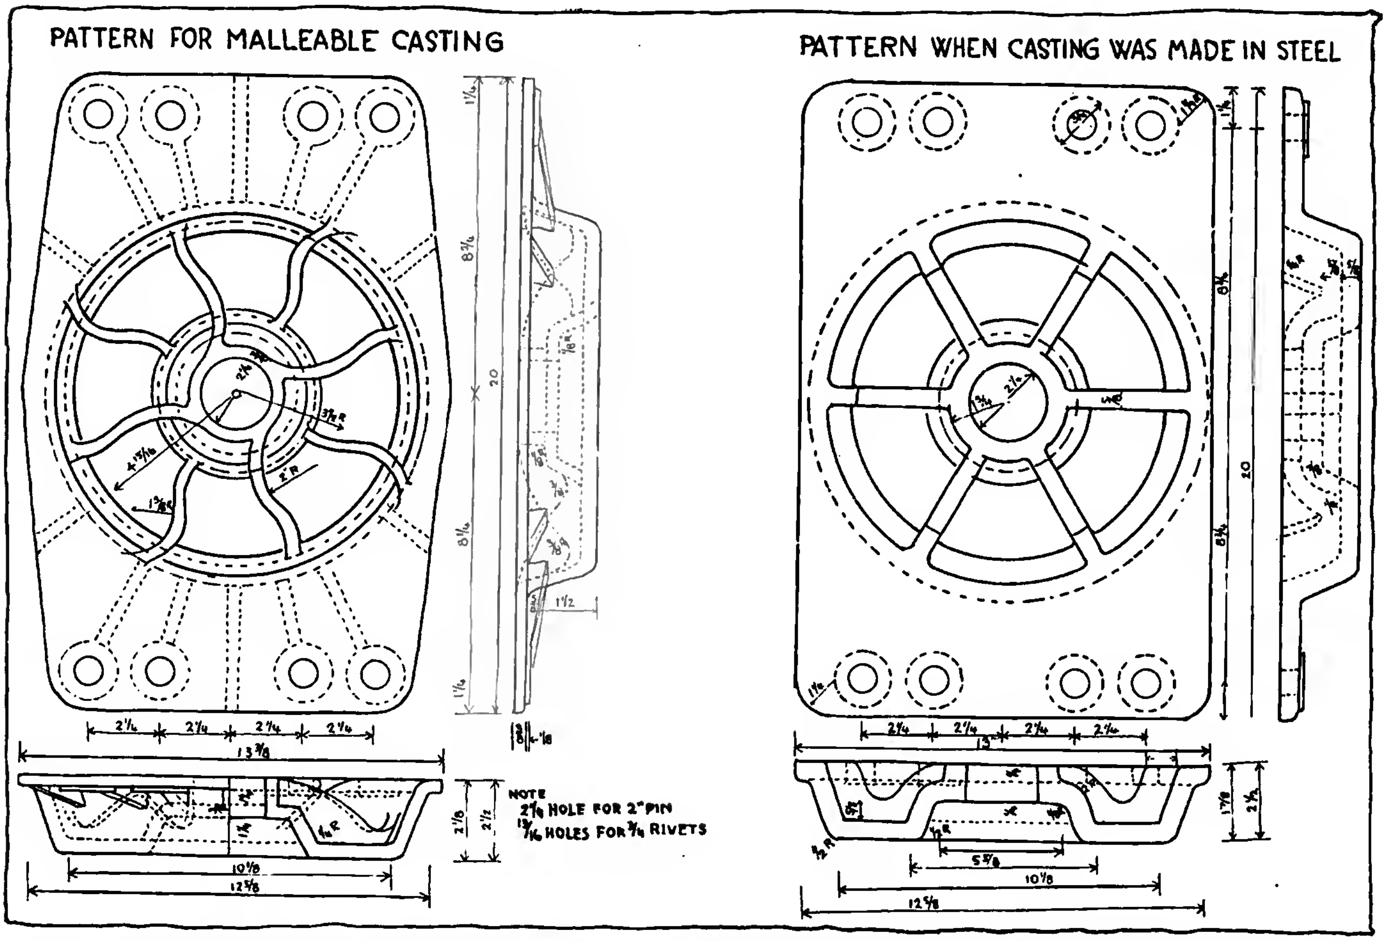

Fig. 10—The malleable iron casting shown above was a failure. The makers wanted to change the pattern, but the work was turned over to steel casting makers who were permitted, however, to change the pattern as shown. The changes are significant

In which Letters from Readers Are Answered and Discussed

Broken Piston Ring Causes Trouble—Dirty Multiple-Disk Clutch Chatters—Discussing Location of Gearbox—Kerosene Through Intake Pipe—Chokes on Account of Heavy Fuel—Clearance Used in the Piston Rings

Sounds Like Broken Ring

Editor The Automobile:—Recently I overhauled my engine, ground the valves and set it up again. It was very stiff to crank, but I thought that was nothing. The engine ran for half an hour without any knocking, but the next morning when I wanted to crank it I could not. It was locked tight. Now, what was wrong? This is the first one I ever overhauled that has acted like this. I do not want to take the engine down if I can help it. I think a ring is broken or out of place.

Pittsburgh, Pa. G. P. Kistner.

—As you do not give the make of your motor nor mention the condition under which it was run after overhauling, it is somewhat difficult to make a certain diagnosis of the case. It is not likely that the trouble is in the piston rings. Of course, this is possible, but it is more probable that the motor did not have sufficient oil when you ran it after overhauling. When a motor runs dry it does not take long for it to stick. The only thing to do is to try to loosen the pistons by putting a mixture of oil and kerosene, the kerosene predominating, in the tops of the cylinders either through the petcocks or valve caps. Then try to work the flywheel back and forth. To do this you may have to use a large wrench or you may be able to work it loose by hand. If you are unable to loosen the motor by this means it will probably be necessary to rig a block and fall and lift the cylinders off the pistons. Of course, if piston rings are broken or out of place it will be necessary to take down the motor anyway. We should be interested to hear of further developments in this case.

Clutch Needs Cleaning Out

Editor The Automobile:—I have a multiple-disk clutch running in oil on a car of a well-known make. When I let in the clutch it takes hold harshly and causes the car to quiver, jump and jerk and makes an awful noise. I have changed the oil a couple of times. Last time I put in powdered graphite and it seems to be worse. Please let me know a remedy for this.

McKeesport, Pa. Austin Conrad.

—Very often this trouble can be cured by giving the multiple-disk clutch a thorough bath in kerosene and gasoline. Mix the kerosene and gasoline about half and half and pour through the plug in the clutch housing. There will generally be a plug at the top of the housing, as in Fig. 1, through which the cleansing material may be poured. Fill the clutch housing to the top and then let the motor run idle for some time before draining out. If there is any connection between the crankcase clutch and gearbox housing, all three, or as many as are interconnected, will then have to be drained out because the kerosene and gasoline cut the lubricant and would leave the bearings dry if they were not drained out and then refilled with fresh oil.

Where there is any connnection between the clutch housing and the crankcase, heavy grease should never be used because it will surely work up into the cylinders and carbonize.

Likes Gearbox on Rear Axle

Editor The Automobile:—As a car owner, I take pleasure in taking part in the interesting discussion now going on in The Automobile regarding gearbox location.

Let me state first that I favor the rear-axle location. I will take up the various arguments against this location and try to show that they are not well founded.

First, it is claimed that the greater weight of the rear-axle construction causes greater tire wear owing to its being unsprung weight. This I do not find to be the case, a set of tires running as far on my rear wheels as on the front. It think it is a good thing to have an unsprung rear axle heavy enough to hold down the wheels while traveling on rough roads, whereas with a light axle the wheels are in contact with the road only part of the time, thereby causing greater liability of stone-bruise, friction between the tire and road and increasing the tendency to skid. I am an advocate of Charles Duryea's doctrine of "most weight on the rear axle." The idea of a unit power plant seems to me as foolish as would that of putting the driving wheels of a locomotive under the tender and trying to push the heavy boiler ahead of them.

Second, as to accessibility, I find that by taking up the floorboards of the rear seat that the rear-axle gearset is in as "get-at-able" a position as it can possibly be located, opinions of manufacturers to the contrary notwithstanding.

Third, it has been argued that a rear-axle gearset would wear out quickly on account of the strains and vibration to which it is subjected. As to this, I submit that all shaft-driven cars have unsprung bevel gears and differentials. If these can be built to stand the strain of the rear-axle location, why not the gearset also?

To sum up: I find the gearset as a unit with the motor bad, because it puts too much weight over the front wheels where it increases the tendency to skid and makes a hard car to steer. It would be just as reasonable to put on a pair of roller skates and try to push a heavy load in front of you. The amidships position is on the whole to be preferred to the unit construction, but even this position has several conspicuous disadvantages, among which are the necessity for using two or three heavy universals, which use up power and add complication, the necessity for heavy cross-members to support the gearset, and the inaccessibility of the clutch.

As to the control of the rear-axle gearset, it has been stated that long connections are necessary between the levers and gearbox and some designers and engineers seem to think that this is a great disadvantage and a very complicated arrangement. That comparatively long rods are necessary with present-day control I admit, but I can see nothing complicated or objectionable about a couple of light steel rods whose length is unalterable unless they are bent, an accident very unlikely to happen because they are located in the most protected position possible. The brakes of most cars are operated by rods much longer than those required for the rear-axle gearset, yet no one ever thought of putting the brakes on the front wheels for this reason.

This question of gearbox location is one of the greatest importance and is by no means settled, different engineers of the highest reputation holding entirely different views; yet in the long run it is the motoring public, the user and not the creator of cars, that settles such questions, and as one who has been following the sport of motoring since its inception these opinions are respectfully submitted.

East Canaan, Conn. DEWEY C. CANFIELD.

Tough on Tarrytown Canines

Editor THE AUTOMOBILE:—You should without delay publish a warning to all motorists with dogs not to pass through or stop in Tarrytown with them, as a quarantine for rabies is being rigidly inforced here. The deputy sheriffs are taking unmuzzled pups from all vehicles and the process of getting them back from the pound is a long and costly one.

Tarrytown, N. Y. MRS. HARRY MICHENER.

Proper Piston Ring Circumference

Editor THE AUTOMOBILE:—1—In fitting new rings to the piston, should the rings be fitted tight to the cylinder walls or should there be a little play left for expansion? If so, how much would this be at the ring joint or lap?

2—How many degrees past upper dead center should the piston be when engine fires or when spark takes place with spark fully retarded? If possible state distance in inches on flywheel.

Spokane, Wash. NOVICE.

—1—Piston ring circumference will vary with the condition of the ring. That is, when the ring is new and cold it will be different than when new and hot, etc. To make a standard comparison of the proper space between the ends of the ring the standard condition of a new cold ring may be taken. A ring under these circumstances should have a space between the ends as shown in Fig. 1 of from .0025 to .003 inch per inch of diameter. This may seem large but when it is known that the expansion of the rings in a circumferential direction is .00001 inch for every inch of ring per degree raise of heat it will not seem too much. Take, for instance, a 3-inch ring. It will have a circumference of very close to 10 inches. Taking 10 inches as an arbitrary figure for the circumference of the ring, we would have, with a raise of 500 degrees in temperature:

$$\text{Expansion} = 10 \text{ inches} \times .00001 \times 500 = .05 \text{ inch}$$

This would seem to be enough to cause the ring to buckle because the allowance according to the above figures would only be about .009 inch at the split for a 3-inch ring. We must remember, however, that the cylinder also expands, causing the ring to spread to a larger diameter which goes to neutralize a large part of the .05 inch of straight linear expansion.

We have no authority for taking 500 degrees as the working temperature above cold because the heat variations are so complex and the changes so quick that the highest temperature of the ring would perhaps be merely a skin temperature and the interior of the ring would be cooler. These figures, however, are food for thought and your question is answered under the direct statement that practice allows .0025 to .003 inch of clearance per inch of ring.

2—It is very seldom that the full retard on a motor allows the spark to take place later than the upper dead center. As can readily be seen, there is no reason that it should because even if the motor were turning over exceptionally slowly nothing would be gained and some power and efficiency would be lost. If the spark occurs exactly at upper dead center, owing to the appreciable lag due to the commencement of the propagation of the flame, the crank will have turned over slightly and the power will be exerted in the proper direction without a knock.

Needs Larger Gasoline Spray Nozzle

Editor THE AUTOMOBILE:—In regard to Mr. Webb's trouble as printed last week, I have had and am still having the identical experience with a car equipped with a Zenith carbureter. My car (Gregoire 18 horsepower) was built in 1910 and the carbureter was probably built for 1910 gasoline. I have had my cylinders rebuilt as you suggested to Mr. Webb, and did not in any way improve matters. It is my opinion that both of these machines (his and mine) are not getting enough gasoline and that enlarging the spray nozzle in the carbureter will help. If Mr. Webb wishes to know the results of my experience I will be glad to let him know.

As to Mr. De Luke's trouble, if he had a 30 by 4 tire instead of a 30 by 3.5 he would have had an awful job getting it on and a worse one getting it off, as a 30 by 4 tire is smaller on its inside diameter than a 30 by 3.5.

New York, N. Y. GEORGE OPPENHEIMER.

Late Spark Heats Motor Badly

Editor THE AUTOMOBILE:—I would like to know the probable cause of excessive heating of water in radiator and motor, and how to avoid it. I have a 30-horsepower Reo, four-cylinder touring car of late 1911 model, which has been used very little. but I find that when on short runs, say of 15 or 20 minutes, at

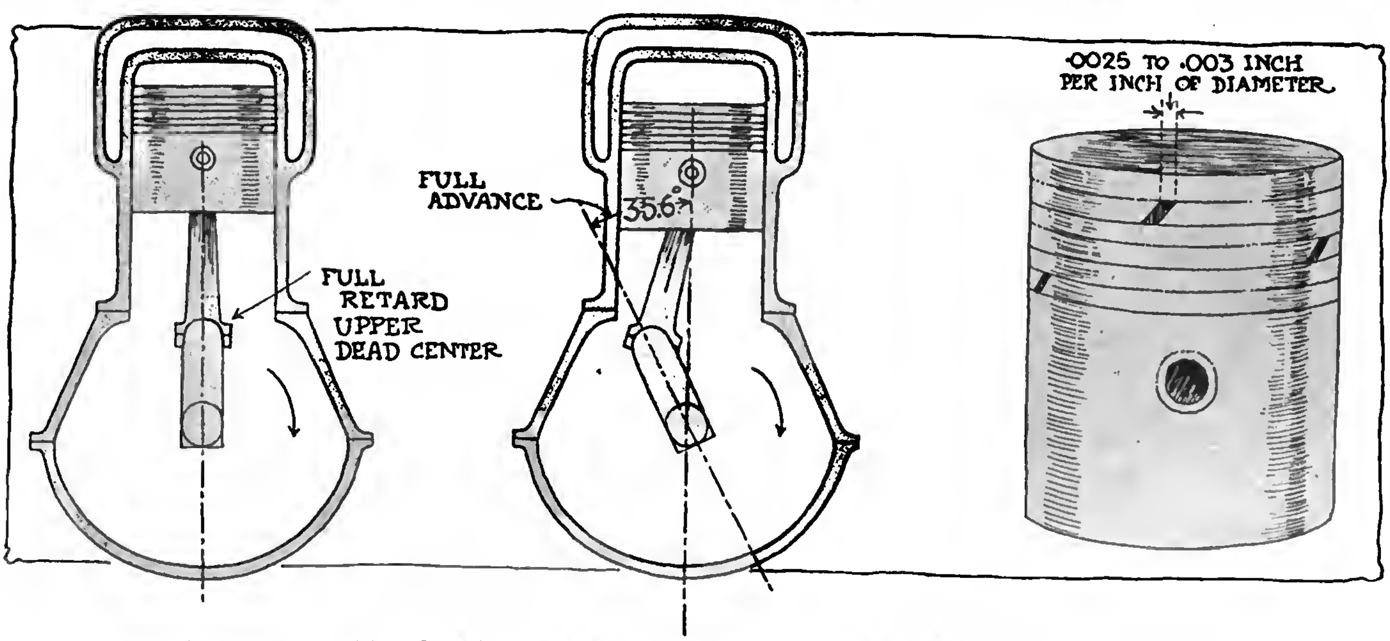

Fig. 1—Proper position of crank at full retard and full advance. Correct clearance at end of piston ring

Fig. 2—Duryea Buggyaut rigged for stationary power purposes

a speed of 10 or 12 miles per hour, the water in the radiator is boiling and the heat uncomfortable for the occupant on the front seat, and another strange feature is that the switch removable handle (National Coil Co.) gets much hotter than the surrounding metal.

Yesterday the car stopped in some loose sand and when I tried to crank it to start again I could not turn it over, and came to the conclusion that the heat was so great that the pistons had expanded so as to bind them; for after the motor had cooled off to a certain extent I had no trouble in doing so.

Now I noticed in The Automobile that on the trial or test of the six-cylinder Packard motor the water entered at 125 degrees Fahrenheit and came out at 145 degrees Fahrenheit.

1—Is not the excessive heat I mention an injury?

2—Does it cause excessive consumption of fuel?

3—What is the ordinary number of miles per gallon of gasoline in such a car as mine, say at 12 miles per hour on ordinary country roads?

4—Are rotary circulating pumps in automobiles liable to get out of order and fail to do their work?

Interlachen, Fla. J. W.

—From your letter it would seem that you were in the habit of traveling with a rich mixture and a retarded spark and that the trouble is in this rather than in any inherent wrong in the car itself. A retarded spark causes the motor to overheat very rapidly and thus will give rise to boiling cooling water. When a retarded spark is coupled with an over-rich mixture the result of the combination of the slow-burning charge with the lateness of the spark makes the motor still hotter. Try adjusting your carbureter to give a little more air and when running advance the spark as far as you can without getting a knock. If the motor tends to speed up too much when you advance the spark, cut down on the throttle. In other words, do not attempt to govern the speed of the motor by the spark, but arrange the spark to suit the needs of the throttle. That is, advance the spark under any circumstances to the maximum possible point and then keep it there until a change in the motor speed necessitates a change in the location of the spark lever. It would be wise for you to clean out the radiator on the possibility that there is an accumulation of sediment therein which prevents it from cooling the water. To perform the cleaning operation, two or three handfuls of soda are dissolved in a pail of boiling water and this solution poured into the previously emptied radiator. Run the motor for a minute or two and then drain out. Repeat this performance about three times, and then another three times with pure clean water until you get the water coming out fairly clear with very little white matter.

The temperature of the water in the Packard test at the Automobile Club of America was as you state. It must be remembered, however, that this was a block test and cannot, therefore, be considered a parallel to road conditions. Cooling water on the road will average in temperature between 180 and 190 degrees Fahrenheit with a correctly-designed and sized radiator.

Another point you must look for when a motor that seems to be in good condition overheats is the fan belt, which may be slipping. The fan bearing bushing sometimes becomes jammed and as a result the fan is so difficult to revolve that the belt just slips around without turning the fan.

Regarding the numbered questions:

1—The heat is dangerous in that the lubricant is working at such a disadvantage that it cannot perform its work properly and some of the bearings or the pistons themselves are likely to seize.

2—The high working temperature does not cause a greater consumption of fuel in itself, although it may be partially due to the admission of too much fuel through the use of a rich mixture. That is, the heat will not cause the use of too much fuel, but too much fuel may cause the heat.

3—Your car is not working at its best economy at 12 miles an hour as far as fuel is concerned, although as far as the rest of the car may be considered it is. That is, although you may not secure so many miles to the gallon of gasoline you will find the wear and tear on your car to be much less. At 12 miles an hour on high gear you should get about 14 miles to the gallon of gasoline.

4—Trouble with rotary or centrifugal pumps as used in automobile work is so scarce that it need hardly be considered. When cooling trouble develops, though, the pump should be examined as well as any other points in the cooling system. Sometimes a leaky hose connection or one which has a loose piece of fabric in the interior is responsible for overheating.

Explanation of Argyll Motor Wanted

Editor The Automobile:—Kindly let me know whether the Argyll engine has a rotary sleeve or not. In the description of the engine that appeared in The Automobile some time ago it was stated that the sleeve was operated by a worm mechanism and the motion was constant, but was somewhat vague as to how the ports were opened and closed.

Yonkers, N. Y. R. A. Fines.

—The Argyll motor was depicted in The Automobile for June 12, and also described. As the motor is important, however, the repetition may be valuable and is herewith reproduced from the previous issue. Fig. 3 shows a transverse section in which the sleeve S will be noted, occupying the annular space between the piston and the cylinder wall. Its action is peculiar in that the motion imparted to it is not merely up and down but is also partly rotational. This will be made clear by reference to

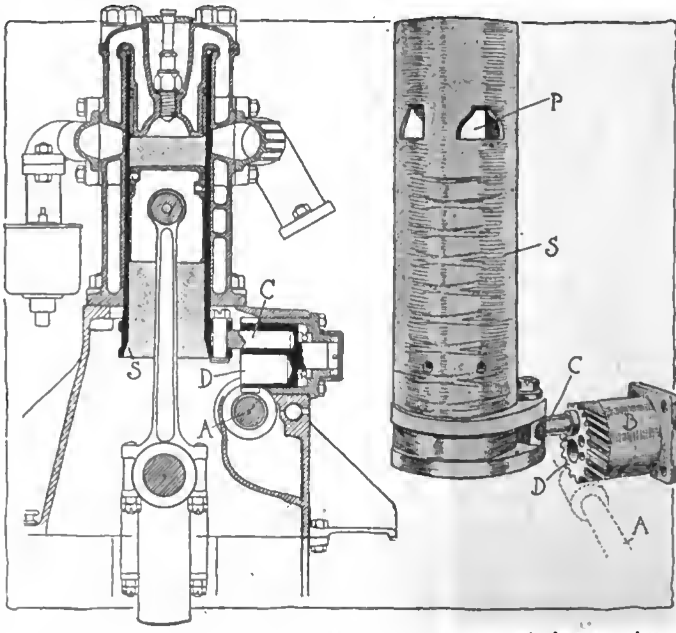

Fig. 3—Argyll sleeve motor, showing operation of sleeve valve

Fig. 3, which shows the sleeve and its operating mechanism detached from the engine. The reciprocation of the sleeve is effected by the action of a small crank C which has a sliding fit in the rotating member D. This latter is carried in the bearing B, which is bolted to the crank casing wall. The operating shaft A, which is equivalent to and occupies the same position as the camshaft in the poppet-valve type of engine, is provided with four worms or skew gears, one at each cylinder, which engage with teeth on the rotating member D, driving it at half the speed of the crankshaft. This reduction takes place at the skew gearing, the camshaft itself running at the same speed as the engine shaft by silent chain.

Two revolutions of the engine shaft, therefore, cause a single revolution of the actuating crank C, which in turn imparts such a motion to the sleeve that any one point on its outer surface will have traveled through an elliptical path on the cylinder wall.

This peculiar motion is the fundamental principle of the Argyll valve. It permits a complete register of opening of the valve port P with the corresponding ports in the cylinder wall while the sleeve is traveling in one direction and a complete closing on the opposite stroke. As the sleeve descends, exhaust is opened and during the return stroke the inlet ports open. This cannot be accomplished by a single up and down stroke of a sleeve with the ordinary straight reciprocating motion, where both valves would necessarily be opened twice.

Using Buggyaut for Stationary Work

Editor THE AUTOMOBILE:—Your reply to Mr. Mathais regarding the best way to utilize a car for power has been noted. If Mr. M. can apply his belt to the flywheel of the engine he will save the needless wearing out of his transmission, propeller shaft, differential and rear-axle bearings. The Service truck you show has a pulley at the rear end, but the Avery truck is equipped with one on the crankshaft at the front end of the vehicle.

Fig. 2 gives an illustration that may interest you, showing a Buggyaut having one wheel removed and a pulley substituted on the end of the crankshaft for the driving roller. This gets power directly from the engine, and the change can be made in 5 to 8 minutes. This is being used not only for shelling corn, as shown, and chopping feed, but for sawing wood and similar purposes where a small power suffices. In the Duryea system it is, of course, understood that the motor lies at the rear of the vehicle with its shaft crosswise, so, although this pulley protrudes from the side, it is actually on the motor shaft directly, just as in the Avery truck mentioned.

Your reply to C. G. F. as to the spelling of "carburetor" is all right, but a good authority like Webster gives preference to the ending "or," and this coincides with many words used in the industry, such as compressor, generator, conveyor, lubricator, distributor, motor and ignitor. It seems, therefore, good business to use a similar ending in this entire "bunch." In fact, if we could as a nation agree that the ending "or" means the "thing which," while the ending "er" means the "one who," it would better our language materially.

Saginaw, Mich. CHAS. E. DURYEA.

Chokes When First Starting

Editor THE AUTOMOBILE:—As I was about to start out this morning at 6 o'clock with my White gasoline "30" I found I could not give the motor much gas on the accelerator without its choking. It started without any trouble, but refused to take the accelerator until I had it running about a minute, after which it worked well. It was rather cool this morning and since it was the first occasion I had to use it that early in the morning, I blame the cool air for the trouble. Although the car is used only about once a week I find it chokes for about a second each time it is started and then it is all right. I have the water turned off around the carbureter because I only use the car during the summer months. I now have the adjustment screw at the lower side of the carbureter turned down or closed because when I open it any more the motor becomes very slow in picking up.

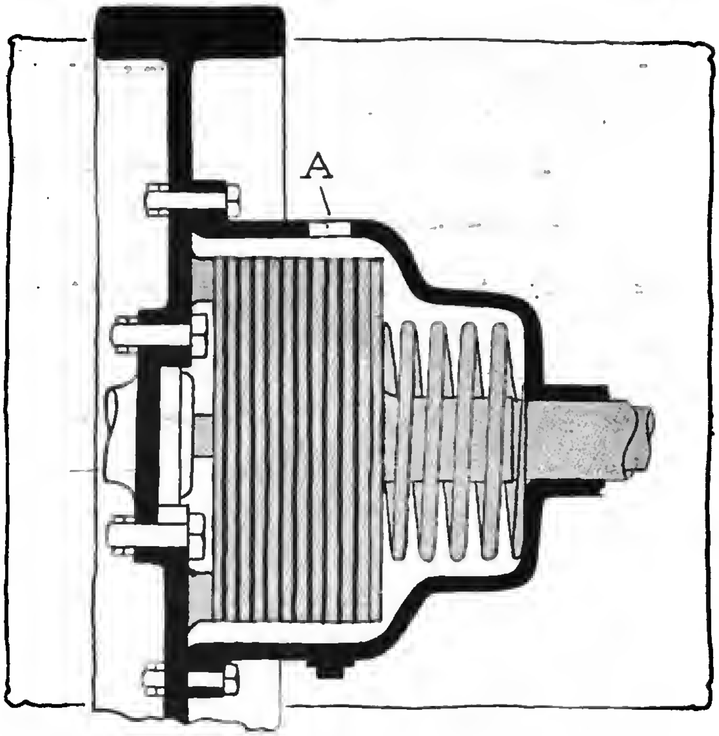

Fig. 4—Clutch should be cleaned by introducing kerosene through A

1—Could you please tell me if the adjustment should be opened and how many notches for good results in summer?

2—What is the small nut near the top of the carbureter marked X there for?

3—Is it necessary to put oil in the crankcase when oil runs freely from the oil level, which is visible by pulling out a rod from the front, beneath the radiator leading to the crankcase?

Richmond Hill, L. I. P. B.

—Bad gasoline, or rather gasoline which is not so volatile as that sold some time ago can be blamed for much of the trouble of this nature that now exists. The gasoline will not vaporize without the application of heat at a sufficiently rapid rate to permit of securing a good homogenous mixture in the cylinders. It is sometimes possible to cure the trouble by admitting a little more air at low speeds, but you stand that chance of having a motor which is harder to start. If the carbureter acts well after the motor has been running a few minutes and pulls well on the hills it would be very advisable to let it alone and to blame the gasoline and not the carbureter. The only real cure for a condition of this kind where it is not desired to have the choking action at all is a dash air control whereby more or less air can be admitted at the will of the operator. To answer your questions specifically:

1—On the average White car, the best results are obtained when this screw, which is the air adjustment, is backed off about twelve or fourteen notches. The screw is first closed down as far as it will go and then the adjustment is made by turning back on it for the distance mentioned.

2—The nut you speak of is one of the hot water cannections.

3—No, as long as oil runs from the level when you pull on the rod it shows that there is enough oil in the crankcase. This is merely a safety level.

Testing Flow of Fuel Through Nozzles

From a Paper Read Before the S. A. E. and I. A. E. by R. M. Anderson.

A STANDARD flow of fuel was first established in order to make comparisons and judge of the accuracy of such laws as have been set forth. The standard flow was secured by means of special apparatus wherewith the various heads could be easily duplicated and accurately measured. This consisted of a vertical brass pipe A, Fig. 2, having an area 500 times the area of nozzle to be tested and of sufficient length to give any desired head. Into the walls of this pipe were soldered thin-walled overflow tubes .3 inch by 1 inch at intervals of 3 inches. These tubes were inclined at a slight angle. The nozzle-holding member B, Fig. 2, consisting of shutoff cock, elbow and drain basin, was so located as to bring the tip of the vertical nozzle 1.25 inches from level of gasoline as determined by outlet tube No. 1. Gasoline was supplied by electrically driven pump C, Fig. 1, keeping a quantity of fuel in tank D. From D the quantity was regulated by valve D1 and flowed into open end of pipe A. Some difficulty was experienced with large flows disturbing level A until the supply from D was slightly damped.

In operation the procedure was as follows: All overflow tubes were plugged except the one corresponding to the head desired. Gasoline was turned on at D1 and at the nozzle until a steady even flow was secured through the overflow tube in operation. This surplus was returned to the pump tank. The gasoline draining from the nozzle-holding member B in a unit of time will be the quantity flowing at the head taken.

To get accurate readings the following precautions were observed:

(1) Gasoline kept at uniform temperature, 60 degrees to 62 degrees Fahrenheit.
(2) Specific gravity of the same, 54 degrees Baumé.
(3) Pump started and run a sufficient length of time to insure uniform flow.
(4) After each reading the nozzle was carefully cleaned. The flows at maximum and minimum heads were checked after the test was finished to make sure the area had not changed.
(5) All readings taken by the same person.
(6) A standard primary nozzle was used and checked with standard gage before commencing test.
(7) All quantities of gasoline measured by the same graduate reading, CM³.

The purpose of the experiments is to determine from a carefully calibrated nozzle the relation of flow to head. Such data will at least give us a better understanding of the flow of gasoline in carbureters and consequently their adjustment. The heads were maintained as outlined and every opportunity was given for the flow to assume characteristic variations. It has been known that at relatively low heads the flow of fuel is subject to slight diminution. The quantities flowing at the various heads represent faithfully an average performance.

The following quantities of fuel and their respective heads are taken as the average of five readings:

Nozzle, No. 57. Diameter, .043 inch. Area, .0014502 square inch. Gasoline, 54 degrees Baumé at 60 degrees Fahrenheit.

TABLE 1.

Reading	H = Head Ins.	Q = Quantity per min. CM³	Q = Quantity per min. Cu. Ins.	Q² Cu. Ins.	Q² + Q	Differences
1.	1.25	27.30	1.67	2.78	4.45	
2.	4.25	50.50	3.69	13.61	17.30	11.85

4.	10.25	99.00	6.04	36.48	42.52	12.96
5.	13.25	114.50	6.99	48.86	55.85	13.33
6	16.25	127.00	7.76	60.21	67.97	12.12
7.	19.25	138.50	8.46	71.57	80.03	12.06
8.	22.25	149.60	9.14	83.54	92.68	12.65
9.	25.25	160.50	9.81	96.23	106.04	13.36
10.	28.25	171.80	10.49	110.04	120.53	14.49
11.	31.25	180.50	11.02	121.44	132.46	11.93
12.	34.25	190.25	11.62	135.02	146.64	14.18
13.	37.25	198.00	12.09	146.16	158.25	11.61

In Fig. 3 the above values of Table 1 are plotted. Q, as might be anticipated, takes the parabolic form. Applying this value in the general formula

$$Q = CA\sqrt{2gh}$$

and solving for C, gives the following:

TABLE 2

H	C	H	C
1.25	.614	13.25	.794
4.25	.750	.....	....
7.25	.766	22.25	.803
10.25	.779	37.25	.822

The above brings out the erratic flow at small with respect to large heads. Any attempt to proportion Q to $\sqrt{h}$ would introduce a variable difficult of determination. This curve is, however, plotted as $Q^2 = H$ and plainly shows its characteristic, viz., a fairly straight line when H is greater than 7 inches.

Realizing this characteristic, Lauret has applied Rummell's water experiments with interesting results. Here the simple addition to Q^2 of the quantity Q gives values more nearly approaching the straight line. In Table 1 these values and their differences are given. The average difference 12.70 cubic inches may be taken as the increment for a No. 57 nozzle where the change in head is 3 inches. Thus

$$\frac{Q^2 + Q}{4.23} = H$$

may be taken as the expression characteristic of the flow of fuel through small orifices with large variations in head.

In general this may be expressed

$$\frac{Q^2 + Q}{C} = H$$

where C is the constant changing for the various diameters of nozzles. Thus with this formula it is only necessary to determine the value of C at maximum head, since this fixes the angle of the slope for the remaining values.

It is necessary, however, to correct the lower values of Q at small heads, since the surface tension under these conditions is quite effective in holding the fuel back. Thus if

$$(Q^2 + Q) = y$$
$$C = A$$
$$H = x$$

we may write the expression taking B, the effect of surface tension from actual tests, as:

$$y = Ax - B$$

Solving for B when $y = 4.45$, $x = 1.25$; $A = 4.23$, $B = .8375$

Thus B and A determine the characteristic of the flow of fuel rough such a nozzle as shown in Fig. 1.

When, therefore, these two constants have been determined and the quantity per minute is given, it is simple to solve for H.

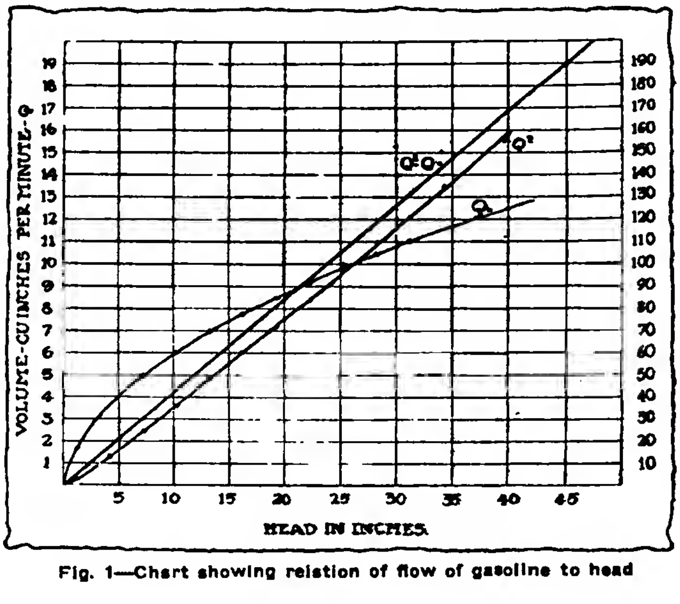

Fig. 1—Chart showing relation of flow of gasoline to head

The Superiority of the Steam Omnibus

From a Paper Read Before the S. A. E. and I. A. E. by Thomas Clarkson.

IN order to avoid misconception with respect to my attitude toward the internal combustion motor using spirit fuel, permit me at the outset to state that I fully appreciate the enormous utility of this type of motor in certain departments of automobilism—that my strictures upon it as applied to bus work should not be regarded as the outcome of a prejudiced judgment but rather as an impartial scientific analysis of the special conditions applicable to bus work and heavier automobilism. This to the end that other fuels besides spirit should be utilized such as kerosene, crude oil, coal or coke, thereby easing the demands upon the spirit motor and its fuel supply, and leaving it greater freedom of development along its special lines of utility.

Passenger Transport Facilities

Increased facilities for passenger transport in cities are constantly in demand. Transport by electric rail motors, both on the surface and underground, has, to some extent, met this demand. But the automobile public service car, or as it is generally called, the motor bus, has already demonstrated its superiority over the rail car or tram.

The main points in favor of the bus over the rail car are its

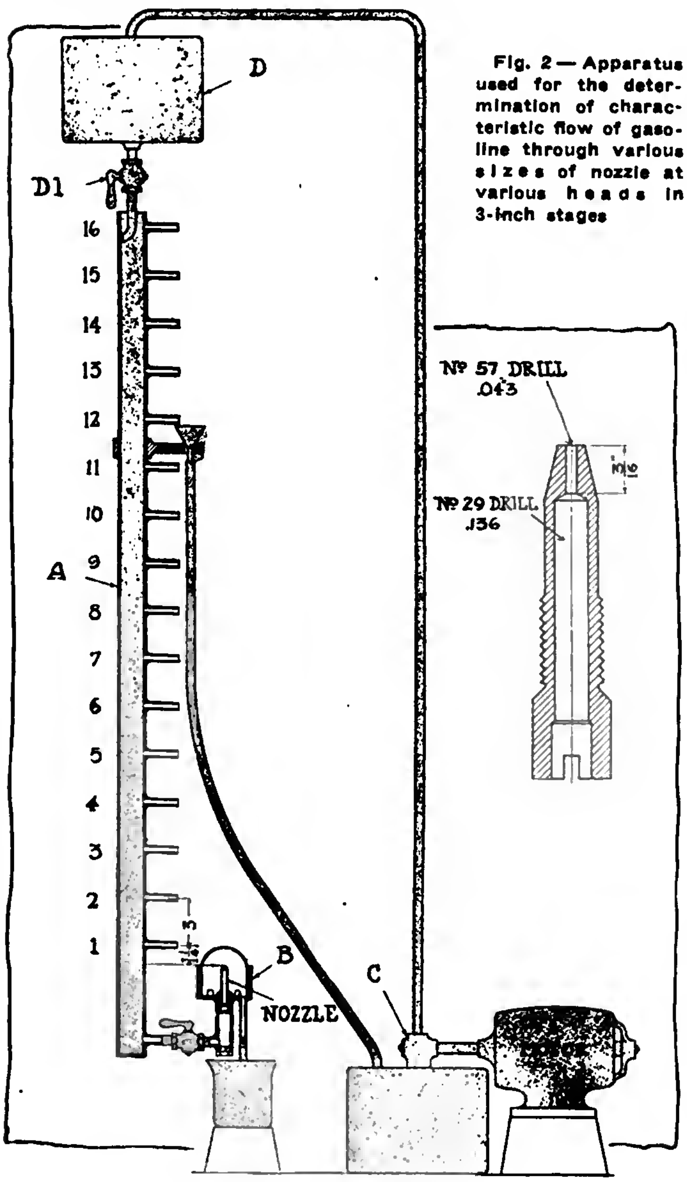

Fig. 2—Apparatus used for the determination of characteristic flow of gasoline through various sizes of nozzle at various heads in 3-inch stages

flexibility and independence of action. Flexibility is the dominant feature, flexibility of route, both as to deviations, extensions and modifications according to traffic conditions, and also flexibility of control in traffic, especially rapid flexibility of speed so as to accelerate promptly in response to traffic conditions whether congested or otherwise.

Complete flexibility is obviously impossible so long as the motors are dependent upon an extraneous power station. The vehicles must be self-contained and the power generated from within. Flexibility I regard as the keystone to the successful solution of the street traffic problem in cities, and I submit that the type of motor which gives most flexibility with the least trouble and expense is the type which will make good. Hence my preference for the steam motor bus in its present perfected form.

A properly constructed steam motor possesses a reserve of energy which is immediately available for a spurt, and acceleration can be speeded up smoothly and without jerk or inconvenience to the passengers.

The control by the driver of a steam motor is simplified and the demands upon his energy and nerve force are reduced to a minimum. This last has an important bearing upon the prevention of accidents and loss of life. The speed is entirely controlled by a foot throttle and no change gears are used.

Reduction of Weight

The weight of a fully laden standard London bus is 13,440 pounds. The unladen weight is 7,840 pounds. This is about 2,000 pounds less than the former weights of both internal combustion and steam buses of the same carrying capacity (thirty-four passengers) which were common a few years ago. This substantial reduction in weight has vastly improved the breed of the bus, for which thanks are due to the police authorities for insisting upon a lighter construction in order to obviate damage to adjacent properties consequent upon severe road vibrations. It was prophesied that this police demand would rule out the steam bus as it did the storage battery electric bus. But it is significant that the first bus to be licensed under the new régime as to weight was a steam bus, a No. 5 National. This was nearly 4 years ago. I claim that the steam bus is still the best, the most efficient and popular, and this view is shared by some of the leading traffic men who control internal combustion motor buses. It is noteworthy that every one of the companies running internal combustion buses in London have been unable to stand the competion of their largest petrol omnibus rival, and have all been absorbed. Today the only omnibus company able to maintain its independence of the great omnibus combine in London is the company running steam omnibuses. The advent of the motor omnibus appears to sound the death knell of the street rail car. The public shows a decided preference for the motor bus and the reason is not far to seek. The bus, owing to its greater freedom and flexibility of action, is easily able to beat the rail car in carrying passengers to their destination in the shortest possible time. Another advantage of the bus is that it can pick up and set down at the edge of a sidewalk instead of requiring passengers to walk in the roadway to or from the car. As a rival to the street rail car the motor omnibus has become a very serious proposition, and the perfected motor omnibus should be of immense value in solving the street traffic problem of cities. The presence of rails in the surface of a common road all automobilists will agree is detrimental to the efficiency of the road surface, and to the vehicles using the road.

The following summarized description will explain the leading points of the National steam bus:

The fuel is kerosene which is vaporized, mixed with air and burned beneath a water-tube generator. The generator is entirely of steel and works at a pressure of 300 pounds (test pressure 1,000 pounds). It is inclosed in a vertical cylindrical case under the bonnet of the chassis, and has a central drum which is closed at the lower end, and fitted at the upper end with a lid for cleaning. This drum is furnished outside with generating tubes of horseshoe form which permit free expansion without strain.

The steam is manufactured in four successive stages:

(a) A preliminary heating of the water to about 140 degrees.

(b) A secondary heating of the water under pressure to about 400 degrees.

(c) Conversion of the heated water into steam at 300 pounds pressure.

(d) Superheating of the steam to about 800 degrees.

The steam is utilized in a simple two-cylinder double-acting reversible engine which drives the rear wheels of the chassis direct through worm gearing at a ratio of about 7 to 1. There is no clutch and no change gears.

The exhaust steam is condensed, filtered and returned to the tank for further use.

The fuel consumption is regulated automatically by steam pressure. The success of the National steam buses is doubtless due in great measure to the excellent "fool proof" generator.

Time does not permit me to refer to the spring, steering, axle construction or brakes of the chassis which are upon standard lines, but there is one detail of the construction of this bus which calls for special notice, *i.e.*, the wheel.

The life of a motor bus is extremely strenuous, probably the most strenuous of any automobile. Its annual mileage is about 30,000. Most of this is done on roads teeming with other traffic; consequently a bus has to stand hard knocks and rough usage. Wooden artillery wheels have proved unequal to the duty. Wheels constructed of cast steel have proved troublesome and uncertain. The National bus road wheel is constructed entirely of forged steel. The spokes are solid drawn tubes welded to a hub which is machined out of a solid forging. The outer ends of the spokes are welded to flanges which are afterwards machined before the rim is shrunk on. The perfect balance of this wheel and the reduction of about 170 pounds in the weight of the four wheels of a bus have materially reduced the wear on tires, and the absence of any internal stresses in the wheel is a great factor in reliability and public safety.

Illumination of the Bus

The proper lighting of a bus has been a troublesome problem, neither oil nor acetylene having proved satisfactory. Electric illumination gives best results. The problem has been to devise suitable electric equipment. This problem has been solved on the steam bus in a very simple and satisfactory manner. About 10 years ago I experimented with electric light for bus illumination. The first equipment was worked from a storage battery, but it did not pan out and electric lighting was discarded. Subsequently a scheme was devised whereby a small storage battery was used in combination with a special dynamo driven by the car and with cutouts similar to lighting systems now used on some pleasure cars. After running this combination in service for several years I abandoned it in favor of a dynamo of the ordinary type directly attached to a small steam motor and without batteries or cutouts. This steam motor runs at a constant speed of 900 revolutions per minute, and the equipment provides current for 150 candlepower per bus. The arrangement has proved completely satisfactory. The cost and weight of the installation have been reduced as well as the cost of maintenance; at the same time greater brilliancy of illumination has been secured. Excellence of illumination has proved a strong point in popularizing the steam bus and in helping traffic receipts.

Some steam buses of the earlier type have been in regular service for the past 10 years and are still running. But the steam bus of today has been evolved during the past 2 or 3 years since the designer and manufacturer took up the business of running buses and maintaining them.

In the short time available for this paper it is impossible to give a history of the evolution of the modern steam bus upon which I have been engaged for nearly 20 years, and as the main object of this paper is to promote a discussion on the relative merits of steam and internal combustion buses, I will briefly summarize a comparison between these two types of motor.

Summary of Costs

The First Cost of the bus appears to be about equal for the same quality of material and workmanship and with a similar rate of production.

Cost of Maintenance—It has so far been impossible to obtain figures which are strictly comparable as to the relative maintenance costs of the two systems. The only way to obtain them would be for the same auditor to examine and analyze the books of both a steam bus and an internal combustion bus company, and to treat both in precisely the same manner as to depreciation, annual overhaul, establishment expenses, etc. Experience shows that the steam bus is in the garage for maintenance a much shorter time than its rival. It is the practice to withdraw an internal combustion bus from service 1 whole day in 10 for maintenance, apart from the withdrawal from service for annual overhaul, which usually takes about 2 weeks. On an average during the year the internal combustion bus loses more than 15 per cent. of its total possible mileage. Total possible mileage means every bus that is licensed doing every journey every day for 7 days a week throughout the year. During the year ended October 31, 1912, the National steam buses lost only 2.847 per cent. of the total possible mileage, and of this only .877 per cent. was due to mechanical failure. That it has been possible to run steam buses under the extremely strenuous conditions prevailing in London so as to give over 97 per cent. of their total possible mileage, whereas the internal combustion bus is not able to do 85 per cent., speaks eloquently both for the superior reliability of the steam bus and its cheaper maintenance.

Points of Superiority

Tires—There is less wear on tires with the steam bus owing to the smooth drive.

Rapid and Smooth Acceleration—In this respect the steam bus is easily demonstrated a winner. The extra steam pressure which accumulates at each stop gives an extra "push off" at re-starting.

Flexibility and Speed—In this respect also a superiority of the steam bus is demonstrated daily.

Illumination—The steam bus is admittedly the most perfectly illuminated.

Popularity—The public shows decided preference for the steam bus.

Vibration and Jerk—There is less vibration on the steam bus. The engine does not run when the bus is stationary for picking up or setting down passengers, and there is no uncomfortable jerk at starting.

Depreciation—Steam buses which I started in regular public service over 9 years ago are still running. I cannot find any internal combustion buses which have been in service so long. My rule for estimating depreciation is to give a 6 years' life, and at each annual overhaul to bring the bus right up to date.

Fuel—A steam bus uses kerosene fuel and so helps to relieve the pressure on the spirit market. With equality of ratio between

$$\frac{\text{price of kerosene}}{\text{price of spirit}} \quad \text{and} \quad \frac{\text{mileage on kerosene}}{\text{mileage on spirit}}$$

there is nothing to choose between either type in cost of fuel. The great increase in the demand for spirit and the absence of a like increase in the demand for kerosene favors the kerosene-fired steam bus.

Drivers prefer the steam bus on account of less fatigue in operation and greater certainty of completing the journeys.

I will conclude the summary by giving the actual figures for lost mileage from all causes during the year ended October 31, 1912, for the fleet of National steam buses in London.

	Per cent.
Buses withdrawn from service for annual overhaul	1.844
Buses withdrawn from service for passing drivers	.045
Buses withdrawn from service for police stops	.023
Buses withdrawn from service as a result of accidents	.058
Buses withdrawn from service in consequence of mechanical failure	.877
Total, from all causes	2.847

I think it will be agreed that these figures are remarkable, especially in view of the fact that the loss of service due to mechanical failure was well under 1 per cent., having regard to the exceptionally severe conditions of the service.

Final Note

It must be obvious that a steam motor which gives such results, under the abnormally severe conditions of public omnibus service, should have useful work to do in other departments of commercial automobilism, say for net loads of 3 tons and over. And it is important to note that for this work the steam motor can use coal or even coke fuel. In this manner a large section of commercial automobilism can be placed right outside the range of the oil trusts which now dominate the fuel supply, and commercial transport of first-class reliability can thus be supplied at a lower working cost than is possible under present conditions with the internal combustion motor.

—

AUTOMBILE SHAFTS SELDOM FAIL—Although it seldom happens that automobile shafts fail, yet cases have occurred under circumstances which lead to the conclusion that the failure has been due to running the shaft at the critical speed of speeds so close to it that vibration has been the cause. As an instance, in one case of failure the critical speed calculated from the dimensions of the shaft was 1,030 r. p. m. The shaft speed under service conditions was limited to 1,000 r. p. m. As might have been expected, had the critical speed been calculated when designing it, the shaft failed in service, though amply strong to transmit the maximum torque developed by the engine.

Trucks in British P. O.

Motor-Driven Vehicles Will Have Superseded Horses in United Kingdom in 3 Years

By Charles Wheeler, Controller of Stores Office, G. P. O., London.

IN 3 years we will have no more horses in the service of the postoffice of Great Britain. At the end of that time the service will be divided among motor trucks, motorcycles, tricycles and bicycles.

There is not a bouse in the British Isles to which mail is not delivered at tbe door. Like a large spider web with its center in London the postal service covers the entire country and includes every habitable spot.

To get an idea of the postoffice organization in Great Britain it may be stated tbat the mail is carried by rail or motor truck from one large postal center to another. Next in order are the smaller wagons which are now to a large extent drawn by horses. Below these are the carrier bicycles and tricycles. The mail is carried by contract, the contracts being let by the government.

The contracts run for periods of 3 years. At the end of this time they are renewable if the service has been satisfactory or if no cheaper metbod of carrying the mail has been discovered. Tbe postoffice has found that one motor truck will replace three horses and still be more economical and hence those now bolding contracts for mail carrying will find that when it comes time for renewal the government will not accept bids on any but motor service.

Now Have 1,000 Trucks in Service

There are now 1,000 motor trucks in the British postal service. These bave proved their economy and money-saving talents very extensively on inter-city parcels post service. A concrete example of this is the run between London and Birmingham. This is a run of close to 100 miles and is now being made by motor trucks instead of by rail. The amount of money saved can be realized when it is understood that the railroads get a little more than one-half tbe face value of the postage, regardless of the distance the matter is carried. On a load of 1,000 pounds with an average charge of 12 cents per pound, the face value of the load would be $120 and of this the railroads would get more than $60 according to the contract with the government. This $60 would go a long ways into the expenses of the run by motor truck.

One of the great advantages of the motor truck is its ability to drop the mail not only at the door of the terminal postoffice of its destination, but to do the same all along the run. Each intermediate postoffice is served at its door and thus all sub-terminal charges are saved. There is no expense connected with bringing the mail from the railroad station to the postoffice in addition to the regular inter-postoffice carrying charge.

All through the interior of the country there are many small towns that have their postoffices some distance from the nearest railroad station. In the past these postoffices have had their mail brought to the station or dropped off the train and then an independent concern has carried the mail over to the postoffice. This adds an appreciable amount to the large percentage collected by the railroads.

In England the direct competition of the motor trucks with the railroads on runs up to 100 miles has now reached such a condition that the railroads will either have to come down in their charges or they will find that the shorter runs will all be taken up by the automobiles.

On the 100-mile run, say such a run as that between London and Birmingham, the London driver goes 50 miles, meets the truck from Birmingham and then drives it back to London. In this way each driver goes 100 miles, the length of the entire run, but is able to sleep at his home every evening.

The automobiles which are in service have been adopted only after a rigorous test. Tbe test for the British postal service extends over a period of 12 months. Every 3 months the data collected are carefully checked up and the results analyzed to determine if the article tested is coming up to requirements. If not it is rejected at once. At the end of a year the whole test is carefully gone over and the figures and costs calculated out to a farthing. If satisfactory the article is accepted as standard. The laboratory test, though extensive, is not relied upon except as a check to the road test. The motor trucks which are now in service are the Wolseley, Dennis, Alldays, Maudsley, etc.

In making the tests the users of the motor truck, motorcycle or whatever it may be, are not informed that it is out on test. It is merely served out to the driver and he uses it as he would any other new piece of equipment. The department, however, keeps a keen eye on these new vehicles or accessories and the drivers' troubles as well as defects in construction are noted. In the motor truck the greatest trouble which has developed, and one which we are still wrestling with, is the tire question. The main trouble with these is the fact that they leave the iron felloes. The postoffice, after exhaustive tests, has abandoned the clincher type of tire and taken up the band type. Only solid tires are used in the service.

One point which has already been learned from experience in the test work is the necessity of over-tiring. Even beyond the limits laid down by the manufacturers the department believes that it is true economy to add extra weight to the tire.

Under test at the present time scattered about different parts of the kingdom are a score of motorcycles. These are reported favorably tbus far and will no doubt become a fixed part of the equipment before long. The motorcycles will do the work of tbe smaller trucks and will be fitted with side cars having a large carrying capacity. These motorcycles are fast and will perform the work in the rural districts to great advantage as far as both the parcels post and the regular post are concerned. A very interesting point regarding the tests carried on by the department is the attention given to new inventions. Every inventor is sure of a fair hearing and scarcely a day passes but someone is not suggesting some time or labor-saving device. These are first passed on in the office and if they seem reasonable are sent out for the 12-month road test.

A most elaborate bicycle service is used for distributing local mail. The aggregate annual bicycle mileage in the postoffice service in the British Isles exceeds 150,000,000. This is attended to by 16,000 bicycles with 50-pound capacity baskets. To give an idea of the efficient service rendered by these an example may be given. We have in the service a bicycle which has covered 160,000 miles and still has the original frame, handlebars, etc. The bicycle tires are 28 by 1.375 inches and are of the double-tube clincher type. The average bicycle tire will give 15,000 miles service.

U. S. Post Office Buys Alcos

Representing an investment of $225,000, one of the largest truck purchases on record has been effected by the Alco company for the purpose of carrying mail in the city of New York. Eighty 3.5-ton trucks were purchased.

The battery of vehicles will have a capacity of 4,300 tons of mail in a day, which means an annual capacity for carrying 1,550,000 tons or 3,100,000,000 pounds. In terms of volume hauled, the array of machines on each trip can transfer 24,000 cubic feet of mail. Figuring on the basis of 18 trips which will be required in a day, the total daily capacity is 432,000 cubic feet of mail, and the annual capacity is 157,680,000 cubic feet.

It is estimated that the trucks will cover a mileage of 1,000,000 miles in a year. The average haul is two miles so that the annual total number of trips will mount to 500,000.

Lined up, one against the other, the 80 trucks will reach a distance of 1,310 feet, or approximately a quarter of a mile.

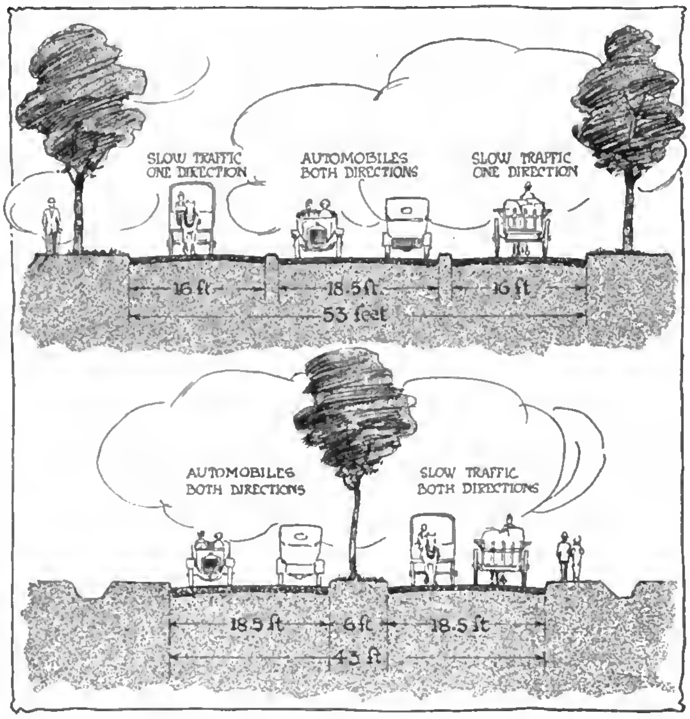
The fleet of trucks was purchased by the Postal Transfer Service, Inc., which has the government contract for carrying U. S. mail in New York.

Special Tracks for Different Vehicles

Suggested schemes to relieve traffic congestion and reduce road dangers

IT is not generally realized how enormous is the loss incurred every year in and about large cities by the congestion of road traffic. Even the cost of living, so much in the air at the present time, is becoming increasingly dependent upon the cheap and easy transport of merchandise.

Before the automobile made its appearance the speeds of the various vehicles using the roads were sufficiently near to each other to render traffic blocks of almost negligible frequency. Nowadays, however, not only has the total number of vehicles in city and suburban roads increased tremendously but there is in addition the aggravating factor of delay caused through the greater differences of speed between the slow and the fast sections of traffic. The higher speed capabilities of the self-propelled vehicle has had the effect of increasing congestion by producing a less regular flow of traffic. This is not entirely the fault of the automobile. It can be more correctly attributed to the fact that there still is, and must ever be present, a considerable proportion of really slow vehicles, making it necessary for the faster ones, in the narrower roads at least, to waste a great deal of time in waiting for opportunities to pass.



Dimensioned cross-sections of roads, showing alternative methods of distributing fast and slow traffic

Since it is the various speeds which apparently produces the undesirable feature of congestion it would appear that a remedy must lie in the establishment of separate roads or tracks for each class of vehicle.

This brings in the questions of increased expense of construction and upkeep, availability of land of the necessary width, and finally, granted these requirements, there is the question of classification, this latter not being the simple matter it might seem at first sight. There are, for instance the passenger automobile which maintains a fairly steady fast speed, and the horse-drawn delivery wagon which travels slowly and makes frequent stops. This would suggest two broad divisions of traffic.

But there are also light fast horse-drawn vehicles of the pleasure type and automobile delivery wagons, the latter stopping frequently along roads bordered by houses. Each of these classes, if the traffic divisions were simply automobile and horse-drawn vehicles, could more suitably be classed with the other division.

To come to practical application of the special track principle a good example is the Avenue des Champs-Elysees in Paris. The arrangement here is shown in the upper illustration on this page. A center track 18.5 feet wide is reserved solely for the use of automobiles traveling in either direction. On each side is a slightly narrower track 16 feet in width for slower traffic, each direction keeping to its own side. Such a road requires a minimum total width of 53 feet. but where this is available no better arrangement could be adopted. The positive raised divisions would, of course, be broken at every crossing and at additional points also, in a residential district where there are few cross roads. It is extremely difficult to say whether a plain road of the same total width, if the same rule regarding divisions were strictly observed, would not be almost as convenient, as it would permit a momentary overlapping in exceptional circumstances. But the human element is then introduced and the careless driver would have a more serious effect on the safety of other road users.

Two other arrangments suggest themselves. That of dividing the road width into two as shown in the lower cross section, and reserving each side for one direction of all kinds of vehicle, or, alternatively, confining one track to automobiles and the other to slow vehicles. A good example of the first of these alternatives is seen in the northern sections of Broadway, New York, and where the road is bordered by houses on both sides this is certainly the better system as it requires less crossing over of vehicles making stops at the houses. If the road runs alongside a railway or river, however, the disposition of traffic shown in the illustration would perhaps prove more convenient, reserving the side next the river for automobiles, since a large proportion of these vehicles are out for plasure and need seldom stop.

A point of some importance brought out by the division of the road into special classes is that of simplifying the problems of the road engineer. It is well known that one of the greatest obstacles to the correct construction of roads has been the necessity of providing a surface that would be suitable alike to the fast rubber tired vehicle and the iron shod hoofs and iron tired wheels of the horse drawn. By confining each class to a special track the surface can be made to suit the requirements of that class.

With the advent of the automobile the old type of water bound macadam road was found inadequate owing to the dust. The dust had always been present, the pounding of the horse being in a large measure responsible, but the rubber tire of the automobile raised it to the standing of a nuisance.

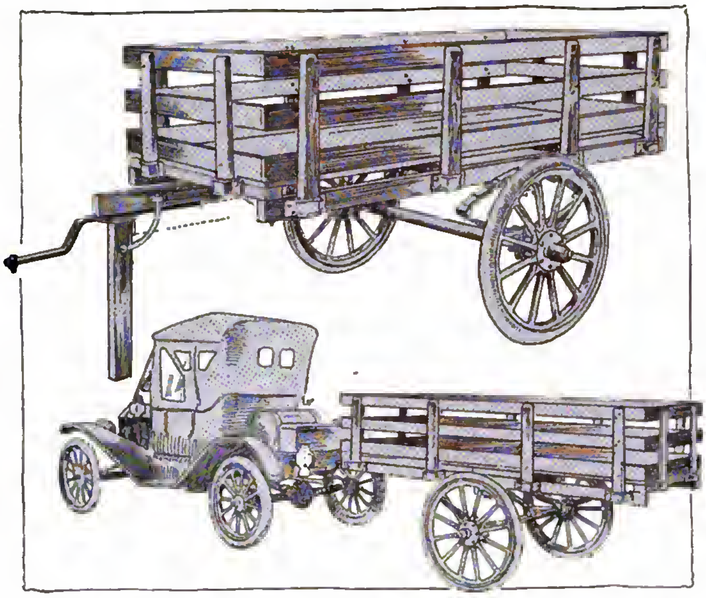
During the past decade efforts have been made to reduce dust by the application of various sprinking mediums, oil being the most successful. But it was soon found that the real solution lay in the entire construction of the road. This has brought about the bituminous road which is more nearly perfect with regard to dust prevention than any previous constructions.

In this type of road, which is growing rapidly in favor, the various layers composing it are bound into a solid mass by the application of a tar or oil-asphalt preparation.

Delivery Trailer for Passenger Cars

Two-wheeled attachment affords facilities for light delivery at small cost

WHILE the passenger automobile is not looked upon as a delivery car, it may be temporarily converted into such a vehicle by the use of some form of trailer. This utilization of motor cars has been made by several of the automobile manufacturers, in Detroit at least, who have put some of their factory cars to freight use by constructing two-wheeled contrivances from surplus parts, such as frames, extra axles and wheels and towing these trailers, putting them to the same service as they would light delivery vehicles.



General view of Detroit two-wheeled trailer Model A, and sketch showing attachment to runabout

Recognizing the demand for such vehicles, the Detroit Trailer Co. has brought out a trailer of this type, constructed entirely of standard automobile parts, as a solution of the light delivery problem. The method of use and the general appearance of the Detroit Trailer is shown in the accompanying illustration, which also shows its attachment to a small runabout.

In enumerating the many uses to which such a contrivance may be put the concern states that it is of special interest to contractors, grocerymen, hardware men, dry goods houses, farmers, summer residents and tourists. The last two types of users may appear rather doubtful to many, but the concern points out that summer residents will find it very convenient in transferring different articles and baggage to and from the city, while tourists are assured that the trailer may be attached to the machine to carry the always great amount of extra baggage needed on a tour, thus leaving the automobile unhampered and not loaded up with baggage.

These trailers are made in two types, models A and B, the former being a two-wheeler and having a capacity of 1,200 pounds. It has a standard I-beam axle and the wheels are of the artillery type of second growth hickory, provided with standard solid rubber tires, size 32 inches by 2 inches. These wheels are mounted on Bower truck type roller bearings, while the frame is suspended from the axle by regular full elliptic automobile springs. The dimensions of the stake body for model "A" are 96 inches length by 42 inches width. The sides are 18 inches high. This smaller type is also furnished with a canopy top, either with a square or round bow, for camping or fishing parties. The makers convey the further information that the vehicle can also be furnished with special springs for sleeping in the trailer, while an ice box attachment fastens directly under the rear end, at extra cost.

The Model "B" trailer is a four-wheeler. It is also constructed of standard truck parts and the body is suspended by semi-elliptic springs from standard I-beam axles, the wheels of artillery type being carried on Bower roller bearings. This heavier model has a wheelbase of 130 inches and a capacity of 3 tons. It is suitable for use in connection with any standard truck of 1-ton capacity or over and is intended for the delivery of coal, lumber and so on. It is claimed to be really a 3-ton truck, minus the engine and transmission. The overall body dimensions are 16 feet length by 54 inches width.

The use of such a trailer for commercial purposes suggests that one of lighter build capable of carrying a few hundred pounds load might prove an exceedingly useful accessory for the private owner. It frequently happens that the touring car, though generally capable of providing space for the assortment of bags and other impedimenta of a touring or camping trip does so at the inconvenience of the occupants. A great deal of the comfort of traveling, for instance, is lost if one's feet are confined to a space limited by carrying luggage inside the tonneau. To avoid this many things that would be found useful during the trip are left at home.

This is where the utility of a light trailer might make itself evident. Desirable constructional features of such a vehicle would be low build, and so made that it could be brought up fairly close to the rear of the car in order to avoid possible trouble when turning sharp corners. A narrow tread would also lessen the danger of accidental contact with the curb or passing vehicles when turning sharply.

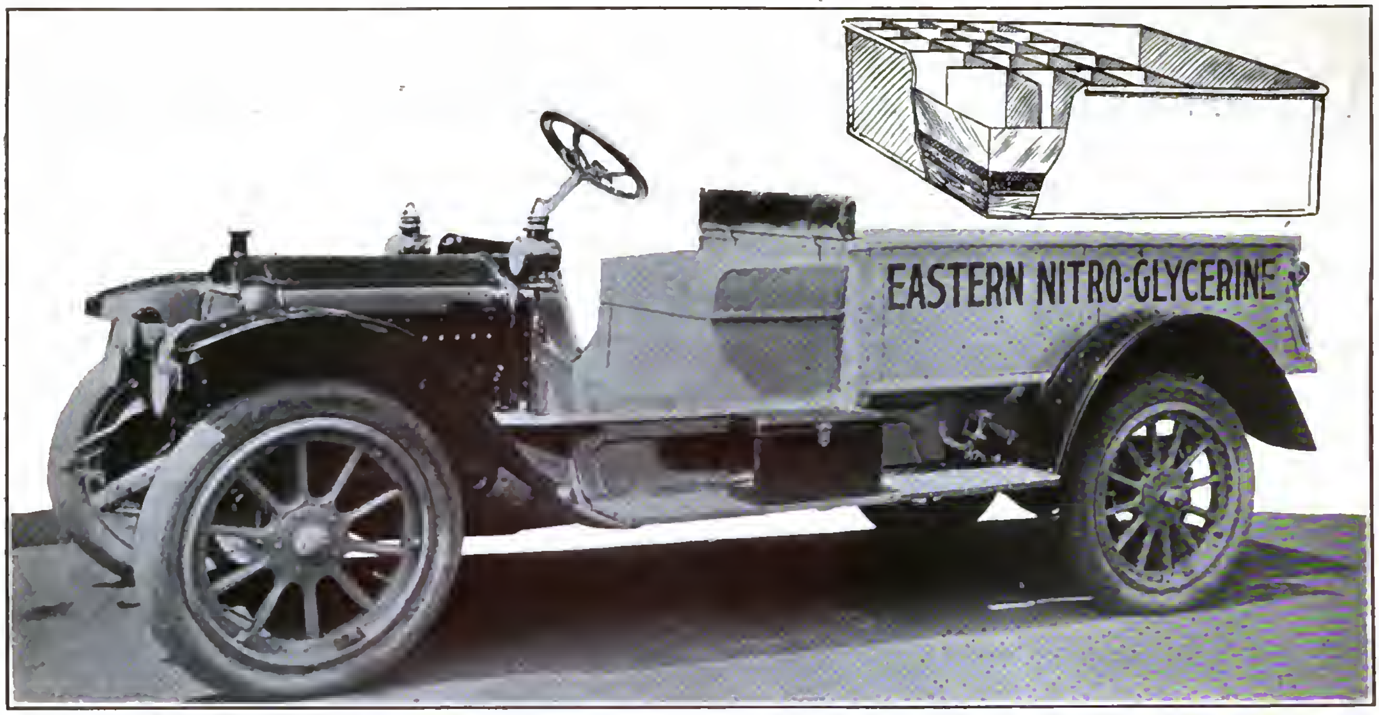
Coal Delivery by Trailer

The high cost of transportation in the retail coal trade has prompted at least one company, the Citizen's Coal Co., of Waterbury, Conn., to adopt the tractor method of delivery in that town. The results are entirely satisfactory, the increased efficiency due to lowering the transportation cost and the greater promptness of delivery obtained, being very marked.

This firm uses a Knox-Martin tractor in connection with three detachable body trailers of 7 tons capacity each. These trailers are of the two-wheeled type and are provided with a pair of hinged jacks at the forward end which support the body when the tractor is withdrawn. On arriving at a residence at which the load is to be delivered it is only necessary to drop the two jacks in place, remove the king pin of the coupling, and the tractor is then available for other service while the trailer delivers its coal.

It takes from 30 to 50 minutes to carry in one of these loads of coal, so that while this body is being emptied the tractor has time to go back to the yard and haul out another body which has been loaded in the meantime, subsequently returning and taking back the other empty body to the yard for refilling.

In this manner the expensive part of the outfit, namely, the tractor, can be kept constantly at work with a high earning capacity, whereas with horses or the conventional motor truck, a large amount of time is necessarily wasted during the loading and unloading, with consequent increase in cost.—*The Carriage Monthly.*



Special White truck used by the Eastern Torpedo Co., Bartlesville, Okla., for the transportation of nitro-glycerine in the oil fields

Special Truck Carries Nitro-Glycerine

Novel Body Designed To Cushion Jolts and Protect Explosive Fluid from Leaks and Heat

IN Oklahoma they "shoot" the oil wells just about the same as a New York subway contractor would blast his way through a wall of rock except that nitro-glycerine is used in the wells and dynamite is used in the subways. In either case, the use of great quantities of a powerful explosive has been accompanied by a ticklish transportation job and periodically the vehicle, the horse and the driver go aviating in atoms and are never seen again—all of which has taught the necessity of protecting the load to the greatest possible extent.

To guard against these events a number of interesting types of conveyance have been developed and a few motor trucks have made single hauls now and then but the Eastern Torpedo Co., Bartlesville, Oklahoma, is the first distributor of explosives to regularly use a motor truck in this kind of hauling. The company is not only using a motor truck but is planning to motorize its entire delivery.

A special body of novel design was built on a standard 1,500 pound White truck chassis and the truck is now in service in Bartlesville, being piloted by a driver who is cheerfully indifferent as to the nature of his load. It was not such an easy task, however, to demonstrate and deliver the truck, none of the White drivers being willing to take the wheel when the truck was loaded. It was therefore delivered but not demonstrated.

The mid-continent oil fields in which the truck is operating cover a vast area south of Bartlesville, including such well-known oil-producing sections as Tulsa and Muskogee counties. The roads run fair to very bad and this fact alone creates difficulty in general hauling to say nothing of the added responsibility of carrying a cargo of explosives big enough to blow Bartlesville off the map.

The Eastern Torpedo Co. sells most of the nitro-glycerine that is used in "shooting" the wells and the company delivers it to some almost inaccessible places. The hauls vary from 3 to 50 miles. When a well has been drilled and the usual 8-inch pipe is in place, it is necessary to quicken the flow of oil by sub-surface explosions and the customary method is to attach a can of nitro-glycerine to a cable and lower it by means of a reel through the 8-inch pipe. When the can reaches the bottom, the simple expedient of dropping a rock on it ignites the charge.

Crosswise and lengthwise of the frame is built a series of sills of heavy, long-leaf yellow pine. This understructure spans the entire loading length. The latter is only 47.5 inches long, leaving an open platform in the rear for the carrying of the reels that are used in lowering the cans into wells. The understructure is covered with a layer of asbestos and on top of the asbestos there is a solid floor of pine. A rubber mat tops the pine floor and on this mat there is a copper pan of full width and length, having sides which rise 5 inches all around.

The asbestos is intended to prevent heat being conducted to the load from either the engine, exhaust pipe or muffler; the rubber mat helps to reduce jolts, and the copper pan is to prevent the fluid from reaching the chassis in case a leak should occur in one of the cans. Each can is placed in a compartment 7 inches by 7 by 17 and there are thirty of these compartments dividing the copper-bottomed loading space. They are formed by poplar boards dovetailed together and running lengthwise and transversely of the frame. These compartments, or cells, have a poplar cover which is divided into two sections, the forward section hinged at the front and the rear section hinged in the rear with a lock in the center.

To facilitate loading and unloading—particularly when the driver alone does the unloading—the right rear fender immediately above the wheel is converted into a step and running board on which cans of nitro-glycerine may be rested while the driver is in the act of jumping down from the truck platform.

To IMPROVE a good automobile calls for more specialized and differentiated positive knowledge than the original construction of it. For a few years yet, untiring study must be the price of prominence in the automobile industry, and it is doubtful if the work can be hired done.

New Warner Motor Is of Block Type

Applicable to All Kinds of Installations Without Serious Alteration—Thermo-Syphon Cooling Is Used

WHEN H. L. Warner severed his connection with the Warner Gear Co. and the Muncie Gear Works, Muncie, Ind., he came to Detroit and organized the Warner-Detroit Motor Works for the manufacture of a motor of his own design. The announcement of this was made in The Automobile some time ago, although no details of the new power plant were given at that time.

The details have now been secured and sectional views of the four-cylinder type to be manufactured are shown herewith. These Warner-Detroit motors have been designed to be applicable to all types of installations without fundamental change. That is, the motor may be suspended either at the front or back of the cylinders on a cross bar, giving a three-point suspension in either case; the flywheel is machined to fit either a cone clutch or a multiple-disk design; the rear end of the crankcase is made to carry a flywheel housing or this may be dispensed with, leaving the flywheel exposed.

The four-cylinder model which is typical of these new Detroit engines is a monoblock type giving a compact design. It is water-cooled by the thermo syphon system, the water jacket running completely around the cylinder casting in the usual way. The water outlet connection extends completely across the top of the cylinders, giving a very free outlet passage for the cooling water. The diameter of the hose connections to and from the radiation is 2 1-2 inches, insuring an adequate flow of cooling water to and from the water-jackets.

The motor is of the long-stroke type, having a bore of 3.19 inches and a stroke of 5.5 inches. This bore was adopted principally so that the engine would come within the foreign requirements. The valves are all on the right side, springs, valve tappets and so on being completely inclosed by cover plates. The crankshaft has two main bearings, while the camshaft is provided with three.

The principal dimensions of the four-cylinder model follow:

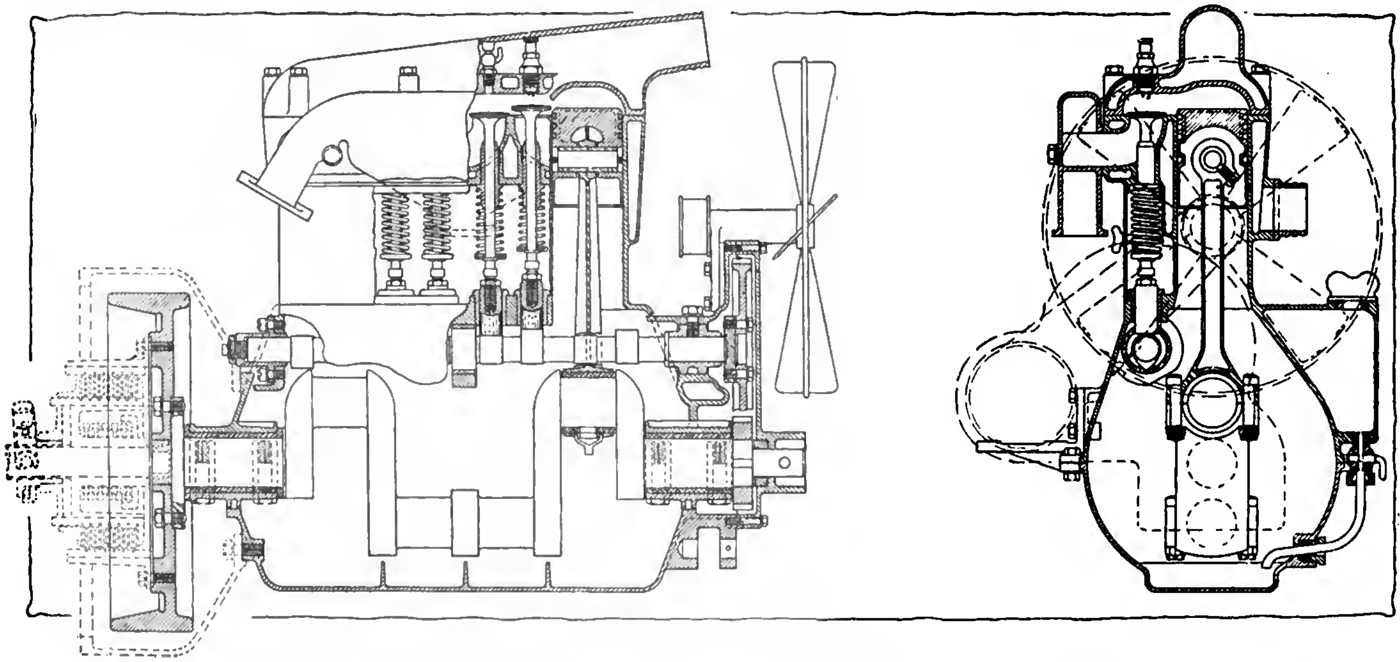
	Diameter	Length
Front main bearing crankshaft	2.25 inches	4 inches
Rear main bearing crankshaft	2.25 inches	4.5 inches
Connecting-rod bearings	2.25 inches	2.5 inches
Camshaft diameter	1.125 inches	
Diameter valves	1.5 inches	
Diameter magneto or timer shaft	1 inch	
Width of cams		1 inch
Width of timing gears		.88 inch
Overall length of motor		31.56 inches
Overall width of motor		19.06 inches
Number of piston rings		3

The motor is made with an integral base on the right side of the crankcase which is machined to take any standard magneto, while either a 1, 1.25 or 1.5-inch carbureter may be equipped.

Lubrication is by means of the conventional splash system, there being individual troughs to contain the lubricant under each connecting-rod, which troughs are cast integral with the lower half of the crankcase. The connecting-rod ends dip into these troughs of oil as they travel around and throw the lubricant up into the cylinders to oil the pistons. The oil reservoir is cast integral with the left side of the upper half of the crankcase, the oil flowing from it down through a pipe into the troughs.

With its long stroke, the motor will develop considerably more power than that accorded it by the S. A. E. formula. This gives the four-cylinder model a horsepower of 16.2, while if the stroke is considered, it figures to about 17.5 at 1,200 revolutions a minute and 24 at 1,600 revolutions.

A very frequent cause for the rut-worn tire is traveling on a surface which has not been frozen solid, but is in such a condition that a thick crust has been formed. At such times the car will be supported from time to time and then will break through, shearing off such pieces of rubber as the knife-like edges of the broken crust will strike. This cannot be avoided unless it is possible to travel by another road, but where the ruts are likely to cause damage this can often be avoided by just simply not getting into the ruts. Many of the roads are posted with signs instructing drivers to be careful in not traveling continuously over the same path in the road. This is especially the case of newly constructed state roads. Despite these warnings, however, drivers of heavy trucks and other horse- and motor-driven vehicles persist in following the ruts made by previous drivers. In the case of passenger automobiles using pneumatic tires this is not only detrimental to the roads but to the tires of the vehicle, as has been explained. It is very easy in many cases to straddle the ruts.



Part sectional views of side elevation and end of the new four-cylinder Warner motor, showing the compact design

SPRINGFIELD, O.—Editor THE AUTOMOBILE—Interchangeable parts rather than standardization of motor trucks is the answer to the question now confronting the United States Government. This solution will not only benefit the government, but will work to the advantage of all big business concerns using large fleets of trucks.

The United States recently asked for the opinions of the leaders of the leading motor truck engineers on the practicability of standardizing a truck for the use of the army.

After considerable thought I believe that the time is not right to attempt the standardization of trucks. The time is ripe, however, for the leading truck manufacturers of this country to get together and agree upon a definite working plan which would help the government and themselves.

The leading motor trucks are designed upon sound conventional principles along the lines of conventional type mechanism.

If the amount of business to be secured would warrant it, we believe that a considerable number of the leading manufacturers could get together and change a few main dimensions on their machines so that the units of different machines could be interchanged.

The main points to be decided are:

1. Uniform width of frame.
2. Uniform length of wheel base.
3. Uniform loading space back of driver's seat.
4. Uniform size of wheels and tire equipment.
5. Uniform sprocket centres.

The simplicity of these changes can readily be seen when it is considered that the last three items are optional in the equipment of most manufacturers.

A glance at the detailed workings of the plan also shows its extreme simplicity.

The hub bearings on certain trucks are practically interchangeable today. It would be a simple matter to standardize the width and length of springs. This would make both axles interchangeable in units without any further changes as the threads are now standard.

The jackshaft and transmission units need to be interchangeable only as to their seats in the frame angle. This could be done easily after the width of the frames has been made standard. To do this, of course, would make it necessary to consider the driveshaft and universal joints units with the transmission and jackshaft.

It would be necessary to standardize the cone clutches only as to diameter and width of face, and as to the length of the clutch between the flywheel and the front end of the drive shaft, or transmitting unit. This would also mean the standardization of the bore of the flywheel for the clutch seat.

Practically all the carbureters, magnetos and wiring and gasoline connections can be standardized with little trouble as the majority of manufacturers are now using standardized articles for these purposes. The only details remaining to be worked out in this connection would be the sizes of the union connections. The length of pipes are very much alike, and other things would make little difference as connections could be bent or coiled up in case of emergency.

It would not be necessary to make such things as pedals, gears, brake and clutch control parts standard, as if these were made of a good, reliable grade of drop forgings there would be hardly any necessity to replace them.

The principal advantage of the plan submitted here lies in the fact that each maker of motor truck could retain his individuality and independence of opinion and judgment in design and construction. To change the point suggested would be comparatively simple as the bulk of the tool equipment of the motor truck manufacturer would not have to be changed in any way.

The new parts that would be necessary, if this plan were put into operation, could be independently tooled up and treated as any other special equipment. These changed parts could be produced with economy if they were ordered in sufficient quantities.

I believe that a board of engineers representing the leading truck manufacturers could work this proposition out to mutual satisfaction. If the government were willing to divide their purchases equally among the companies represented in this mutual plan, the details could be satisfactorily worked out.

Especially in the case of trucks for use of the War Department would this plan be beneficial. In times of real war, or even during maneuvers there is so much haste that it would be impossible for the soldier-mechanician to make any small or delicate adjustments. It would be far simpler to interchange entire units of construction from trucks which are out of commission to other trucks with little delay.

It appears to the writer that it would be impossible to put a new gear in a transmission or a new differential in a jackshaft, or even a new piston in the motor. It would be much simpler, and could be done with little delay by the placing of entire units into the remaining trucks. This would mean only the taking out of bolts and nuts and would require little or no real mechanical skill and adjustment.

To my mind this plan possesses all the advantages of the standardization of motor trucks without any of its disadvantages. I firmly believe that it is practical, and would effect a great saving for the government and the motor truck manufacturer interested if it were put into operation—CHARLES BALOUGH, Kelly-Springfield Motor Truck Co.

Interested in Spring Development

LOS ANGELES, CAL.—Editor THE AUTOMOBILE:—The excellent article in your number of April 17, 1913, by Prof. Dr. Riedler of Berlin, Germany, on springs for automobiles, and his opinions on shock absorbers which are hereinafter quoted, may make it of interest to the readers of automobile literature to follow the progress of automobile spring suspension to its latest development.

From Dr. Riedler:

> "In running over a ridge or furrow the wheels no longer hit the road l[illegible] but tbe higher or lower surface of tbe obstacle, and the vehicle spring, a[illegible]ing compressed by the first impact, has no chance to rebound toward t[illegible]d but must spend its stored energy upward against the heavy v[illegible]y, which is thrown upward until the springs are entirely extended. [illegible] this action the vehicle body is unavoidably thrown up so high that when it comes down again by gravitation it compresses the springs till the frame comes down hard against the axle. Such excessive oscillations of springs can only be avoided by cautious driving. Dampers on the spring action can be justified only when they guard against excessive upward movements of tbe vebicle body. They should therefore take effect only at the moment when such movements begin, but not before. Most dampers, and particularly all the elbow-joint dampers, work on just the opposite principle and are therefore valueless. Hydraulic dampers can be made to operate correctly, but are too complicated (umständlieb)."

It is unquestioned by Dr. Riedler or any other authority that there is only one weight of body and passenger load for a given spring suspension, which will give ideally comfortable riding, for with a heavier load the axles will be hit sometimes by the frame, and with a lighter load the springs will be stiffer than are comfortable, and in consequence, automobile manufacturers build for the heavier, not the lighter load, as pounding on the axles is ruinous to both body and gear.

If reliable devices to control recoil were available, which would allow lighter springs with 10 or 12 inches of clearance over their axles to nearly close on an excessive bump, without allowing excessive overthrowing on its recoil, they could improve materially on present day practice of striking a rubber bumper upon closing 4 or 5 inches in order to keep the passengers in the car, the theory being that with slight compression there will be slight recoil.

Most manufacturers of so-called shock absorbers (dampers) have assumed that retarding means to keep the springs from closing or hitting the axles, and is desirable and necessary. They have not profited by their study of the forces which are acting or they would know that when the excessive opening, or recoil, or overthrow of the springs, as it is variously called, is stopped by some frictional dampening means, not by spring means, there is no downward acceleration of the vehicle body due to the back-pull of the vehicle springs, hence only the force of gravity is acting on the automobile body, and if the springs are of proper weight, the axles will not be hit by the frame. Any friction which retards the closing of the spring, injures the resiliency of the same and makes for harder riding and that chattering motion so undesirable.

The action of vehicle springs on a rough road with reference to the comfort of the passenger is as follows:

As the wheels surmount an obstacle in the road the springs are compressed, and before final descent over the obstacle, the recoil has projected the automobile body and passengers upward. This momentum of the body opens the springs above their normal without load, and at about the moment when the wheels have rolled over the obstruction, still further opening the springs, the body is pulled back to earth by gravity plus the back-pull of the overthrown springs, while the passenger is pulled back to earth more slowly because by gravity alone, and this is the reason he is left in the air, and when he strikes the seat, it is on its secondary ascent to meet him, and the contact is never pleasant.

Now let us analyze the effects of the different types of dampers, up to this time available:

The elbow type is a friction damper having equal friction in both directions and if tightened enough to effectively overcome recoil above the normal, it so injures the spring resiliency upon compression as to destroy its usefulness as a comfort device.

The elbow type in which the friction is obtained by a cam, which upon being turned compresses springs, enclosed in the device, injures resiliency of the vehicle springs, and is also a fixed neutral position device which allows free movement of the axles for slight road variations, without frictional retarding effect upon the opening or closing, but if set for the neutral position when two passengers are riding, upon the load being increased to seven passengers it is in the jammed position when the car is at rest instead of in the neutral one, which is most undesirable.

The spring recoil check, in its various forms, whether a spring on the end of a strap, in the form of a spring-controlled toggle, or a spring directly connected between axle and frame. only adds to the back-pull of a vehicle spring when it has [illegible] thrown above the normal, and therefore assists the s[illegible] in pulling the automobile body to earth before the passen[illegible] has started to descend.

The strap can be made to keep the spring at or slightly below normal and therefore do away with back-pull, but on the recoil of the spring, if the body is so suddenly stopped, the passenger is projected upward and comfort is not added to, although strains on the mechanism are undoubtedly somewhat modified.

The hydraulic device, of a piston and piston rod, descending freely through its stuffing box, cylinder and contained liquid when the spring closes, and on the recoil forcing part of this liquid through an adjustable opening, thereby giving the desired amount of friction, will undoubtedly operate satisfactorily, but with the leakage of the liquid through the stuffing box, and the pressure being upward of 200 pounds per square inch against it, with the consequent admission of air to take the place of the liquid so lost, the device becomes elastic on its back-pull, for what is more elastic than compressed air, and in addition, this spring recoil check is obtained with much attendant and cumbersome weight.

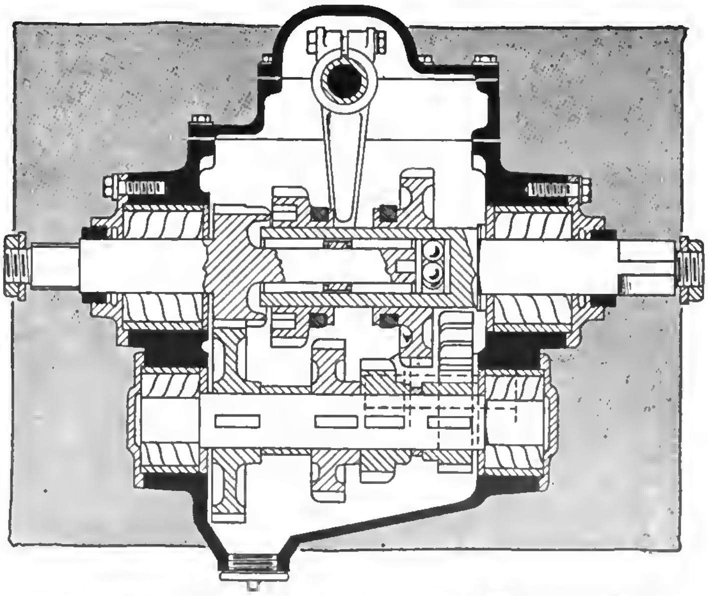
A Spring Controller—The writer is the patentee of a device which is designed to overcome the several faults enumerated above in connection with the various forms of shock absorber and in particular to overcome the secondary back-pull of the vehicle springs after passing over a lump in the road surface. In this device a series of friction plates is arranged in conjunction with a rachet connected to an outer lever in such a way that on the upward throw of the axle the rachet slips and the friction plates remain stationary but on the return stroke the plates are put into action with a retarding effect on the spring motion. This virtually eliminates the rebound of the vehicle spring and therefore only the force of gravity is acting on both the automobile body and passenger after a sudden lift. Hence they descend together and the shock is absorbed by the long throw of the vehicle spring.

Many of these devices are in use in this city and one set has traveled around the world.—H. C. TURNER, Vice-President Turner Oil Co.

Testing the Factor of Safety

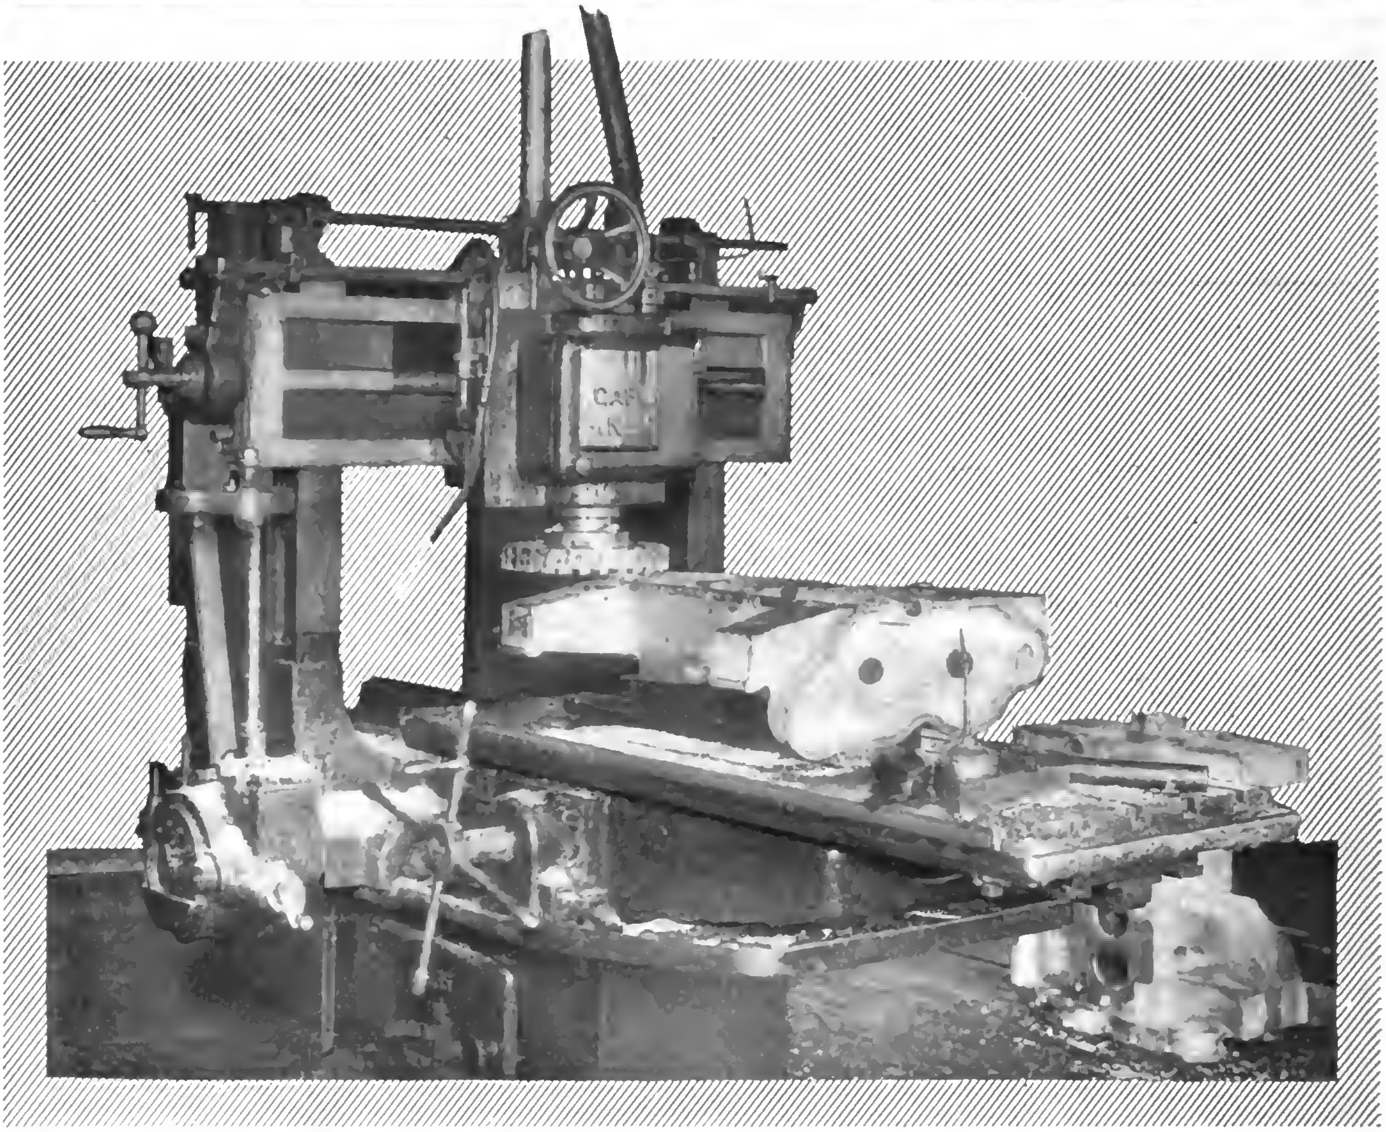
KALAMAZOO, MICH.—In order to prove conclusively that the factor of safety in their transmission set was high enough to insure long life the Fuller & Sons Mfg. Co., of Kalamazoo, Mich.. recently subjected one of their standard 25-35 horsepower gearsets shown in the accompanying illustration, to a severe test as follows:

A standard transmission taken from stock, was securely bolted down to a solid foundation. A large steel bar held the rear mainshaft square end from turning, and the gears were shifted into the low speed. Next a heavy steel bar, 8 feet long, was placed on the front end and a man of average size placed his weight on the long bar at different positions, moving out toward the end of the long bar in steps of 3 inches. This was done repeatedly until a twisting movement, equal to 229 horsepower was exerted on the gears, shafts, bearings and case, before any fracture occurred. In other words, the transmission stood a twist equal to a 229 brake horsepower load, a sufficient indication that the 25-35 rating is conservative and the factor of safety such as to meet all possible conditions of use in the automobile. Tests of this character are especially interesting nowadays that manufacturers are finding the public more intimately acquainted with automobile construction than in the past. The factor of safety is a most important consideration in any part.



Sectional view through the gearbox of Fuller & Sons Mfg. Co., tested recently

Factory Miscellany



Crankcase milling machine used in the factory of the Moon Motor Car Co. at St Louis, Mo.

IN the factory of the Moon Motor Car Co., St. Louis, Mo., a special milling machine of the type shown in the above illustration is used for milling the aluminum crankcases used on Moon engines. This machine carries a 16-inch diameter inserted tooth cutter, the teeth of which are made of a special steel costing over $1 per pound. The milling of either the top of bottom of the upper half of crankcase is accomplished with only two cuts, the first cut removing .125 inch of metal. After this cut is taken, the crankcase is removed from the machine, put in a special chemical bath and allowed to set for several days in order to remove any strains that may be in the metal. It is put back in the machine and a finish cut of .012 is taken.

The bottom of the upper half of the Moon crankcase is 21 by 33 inches and the first cut requires 17 minutes. The second cut requires 11 minutes. The top of the upper half of the crankcase is 12 by 24 inches and the first cut here requires 12 minutes and the second 8 minutes. This also includes the milling of the magneto brackets and the self-starter bracket. This machine is operated entirely by one man and although several days elapse between the time the first and scond cut is taken on each crankcase no time is lost, as each crankcase is numbered, dated and put in its chemical bath, thus allowing one to be taken out as fast as a fresh one is put in. As may be imagined, the saving effected over the old methods by the use of this machine is very great.

FACTORY GROWTH IN QUEENS—The Goodyear Import Co., which is constructing an eight-story $225,000 factory at Jackson and Honeywell streets, Long Island City, recently made application to build a five-story $35,000 addition to the plant. The Ford Motor Co., which is about completing an eight-story building at Jackson avenue and Harold street, also has purchased an entire block adjoining and bounded by Honeywell street, Fifth and Jackson avenues, and will erect a ten-story building at a cost of nearly $1,000,000. The Neptune Motor Co., which recently took out permits for the erection of a five-story factory in addition to its present plant at Jackson and Crane streets, applied also to erect an $18,000 one-story brick foundry on a plot 100 by 123 feet.

Mather Spring Addition—Plans are being drawn for an addition to the factory of the Mather Spring Co., Toledo, O. The business of this concern has grown so rapidly that the additional space is necessary.

Palmer Starts First Factory—The Palmer Motor Car Co., Detroit, Mich., recently organized, has begun the construction of the first unit of its plant which will be located at Ecorse, a Detroit suburb. The structure will be of reinforced concrete construction, one story, and 80 x 355 feet.

Apperson Taking Bids—The Apperson Automobile Co., Kokomo, Ind., is taking bids for the erection of a three-story factory building to cost $20,000.

Plant for Bellefonte—The recent incorporation of the Bellefonte Automobile Mfg. Co., maker of the Bellefonte automobile, has bought a factory at Bellefonte, Pa.

Fire in Automobile Plant—Fire was recently discovered on the second floor of the three-story brick building occupied by the Ohio Electric Automobile Co., Toledo, O. The flames originated from spontaneous combustion in waste matter.

Ford's Seattle Plans Finished—The plans and specifications for the Ford Motor Co., Detroit, Mich., assembling plant to be built at Seattle, Wash., at a cost of $400,000, are finished. Bids were received on the building on June 10. Considerable machinery will be bought.

Cole's $175,000 Plant—A contract has been let by the Cole Motor Car Co. for a large addition to its plant in Indianapolis, Ind., and work has been started. The contract price, exclusive of machinery, etc., is $175,000. The structure will be four stories high and of brick, steel and reinforced concrete construction.

Iron Foundry for Lewis Electric—A new gray iron foundry to supply castings used in the construction of motor parts manufactured by the concern is to be built by the Lewis Electric Welding & Mfg. Co., in West Toledo, O. A specialty of medium and light-weight high-grade iron castings will be made.

Oakland at Full Capacity—The Oakland Motor Car Co., Pontiac, Mich., is running its plant at capacity to fill orders and more than 1,100 men are employed. During May the daily shipments averaged fifty cars. There are over 1,200 dealers. The total business for the season will be approximately $15,000,000.

Amplex Building 7,000 Motors—The Amplex Motor Car Co., Mishawaka, Ind., is building 7,000 motors for the Empire Automobile Co., Indianapolis, Ind. Mr. Mead, president of the Amplex company, said the company would make 50 motors in July, 150 in August and after 500 motors per month until the present contract is completed.

College Men in Factory—Many college men from all over the countrty are planning to work during the summer vacation in the factory of the Goodyear Tire & Rubber Co., Akron, O. The company recently requested the college men in the company to write to their colleges asking for men, and the responses have been numerous.

Overland Planning More Buildings—The Willys-Overland Automobile Co., Toledo, O., is having plans drawn for $200,000 worth more of new buildings. A brick testing track is being constructed. The Kinsey Mfg. Co., a branch of the Willys-Overland Co., is arranging for the construction of a warehouse which will approximate 300 feet in length.

Explosion in Goodyear Plant—A gas explosion in the basement of the six-story office building of the Goodyear Tire & Rubber Co., Akron, O., recently started a fire which caused $10,000 damage. The explosion ripped a hole in the first floor of the building, and the fire which followed caused four hours' vigorous fighting by the fire department before it came under control.

Newark Secures Pharis Tire Factory—By an agreement entered into recently by officers of the Pharis Tire & Rubber Co. with the Board of Trade, Newark, O., secures an industry which Columbus and Chillicothe have each sought. The rubber concern agrees to employ not less than forty men at an average yearly salary of not less than $700 during the first 6 months, and will at once install a plant requiring nearly $30,000 worth of machinery at the outset.

Automobile Plant for Meriden—President C. B. Schoemehl of the Waterbury Battery Co., Waterbury, Conn., is the prime mover in the plan to establish an automobile factory in the idle plant of the Meriden Woolen Co., Meriden, Conn. It is expected to employ 300 men at the start. Outside capital will have about 75 per cent. of the investment of $200,000, and Meriden men will invest the remainder if the scheme goes through. The car to be made is a $1,000 car and has been manufactured on a small scale in New York.

New Timken Roller Bearings Factory—Officers of the Timken Roller Bearings Co. announce that they will erect an addition this summer which will provide for the employment of 200 additional men. Plans for the buildings have not been prepared and will not be commenced until negotiations for additional land are concluded. The company, however, will try to have the plant completed by fall. Either two or three buildings of reinforced concrete will be constructed. J. G. Obermier states that the improvements will adjoin the present plant.

The Week in the Industry

Engineer — Dealer — Repairman — Garage

View of a day's output of the Hupp Motor Car Co., Detroit, Mich. Cars are lined up for inspection

Circus tent in yards of Hupp Motor Car Co.'s factories, Detroit, Mich., used for a temporary test department

CANADA RECIPROCATING ON PASSPORTS—In view of the fact that the United States government has agreed to recognize membership cards in the Ontario Motor League as passports, and that automobiles entering at one part are allowed to make clearance at another, the Motor League has decided to petition Hon. J. D. Reid, Minister of Customs for the Dominion, to allow a similar privilege to the United States motorists.

DAHL TIRE IN PORTLAND—The Dahl Punctureless Tire Co. has settled in Portland, Ore.

HIGHWAY CONVENTION IN VANCOUVER—The annual Pacific Highway Convention will be held in Vancouver, B. C., August 11 to 13th.

NORMAN FORD PORTLAND MANAGER—F. B. Norman has become manager of the Portland, Ore., branch of the Ford Motor Co., Detroit, Mich.

BOULDEN WITH SERVICE RECORDER—H. T. Boulden has been made vice-president and general manager of the Service Recorder Co., Cleveland, O.

MURDEN KNICKERBOCKER MANAGER—H. H. Murden has been appointed factory manager of the Knickerbocker Motor Truck Mfg. Co., New York City.

MACDOUGAL HAYNES SALES MANAGER—J. E. MacDougal has been appointed sales manager of the Pittsburgh-Haynes Automobile Co., Pittsburgh, Pa.

THATCHER OAKLAND TREASURER—H. H. Thatcher has been appointed treasurer of the Oakland Motor Car Co., Pontiac, Mich. He will also continue as supervisor of Michigan sales.

J-M ABSORBER BRANCH OPENED—A sales branch for the J-M Shock Absorber Co. has been opened at 425 North Meridian street, Indianapolis, Ind. M. Matthews is manager of the new branch.

ADDING TO GARAGE—The Seguin Auto & Cycle Co., Seguin, Tex., is building an addition to its garage, and when completed will be 50 by 100 feet, with the repair shop, 20 by 50 feet, of fireproof construction.

WOOLER JOINS CONTINENTAL MOTOR—E. Wooler has become a designer for the Continental Motor Mfg. Co., Detroit, Mich. He was recently in the designing department of the Rolls-Royce, Ltd., a British automobile concern.

FIRE IN PHILADELPHIA GARAGE—Automobile materials and several machines left for repair work were burned recently in a fire which did damage roughly estimated at $10,000 to the building of the Empire Auto Top Co., Philadelphia, Pa.

MORE AUTOMOBILE FREIGHT CARS—Included in an order for $10,000,000 worth of new equipment now being received by the Atchison, Topeka & Santa Fe Railroad are 1,400 new furniture cars which will be used mainly in the automobile trade in the southwest.

OVERLAND'S N. Y. $200,000 LEASE—C. T. Silver Motor Co., agent for the Overland car, has leased 1739 Broadway, with Nos. 237-241 West 55th street. It intends to make extensive alterations. The district has been gradually absorbed by theaters and restaurants. The lease calls for $200,000.

BOULEVARD 20 MILES LONG—After several years of effort on the part of automobile interests and good roads' advocates, the building of a boulevard connecting Indianapolis, Ind., and Noblesville is assured. The new boulevard will be more than 20 miles in length. It will be 60 feet wide.

LEAVES PEERLESS TRUCK DEPARTMENT—R. S. de Milkiewicz, Esq., who has been connected with the Peerless Motor Car truck department, Cleveland, O., has severed his connections with this firm. Mr. de Milkiewicz announces his affiliation with the American Locomotive Co., and on July 1 will be located in the New York branch of its truck department.

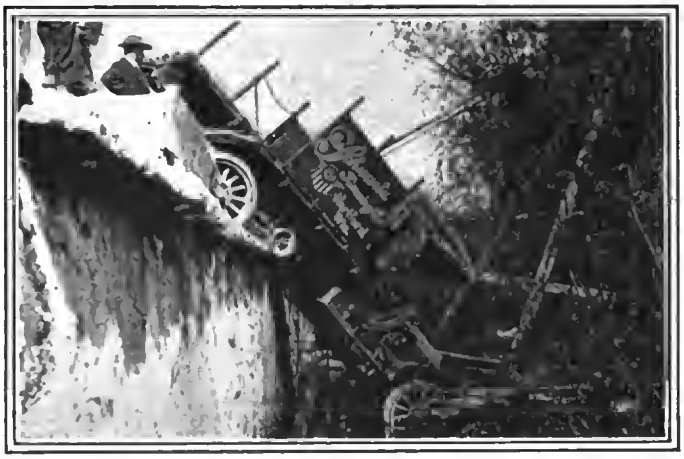
Service squad used in hurry calls by Bishop, McCormick & Bishop, Paige-Detroit dealers in Brooklyn, N. Y.



KisselKar truck plunged over a 10-foot stone wall with no more damage resulting than a flattened and twisted running board

HANDLING BRAENDER TIRES—The Braender tires are being handled in Baltimore, Md., by the Wyma Park Garage, with F. S. Brown as manager.

MILLINGTON RESIGNS FROM BUDD—T. H. Millington has resigned as general manager of the Detroit, Mich., plant of the E. G. Budd Mfg. Co., of Philadelphia, Pa.

THOMAS FEDERAL TRUCK MANAGER—C. K. Thomas has been appointed manager of the Federal Truck Co., of New York City, distributor of the Federal motor truck.

KLOSE RESIGNS FROM MAXWELL—O. W. Klose, district manager for the Maxwell Motor Car Co., in Minneapolis, Minn., recently resigned from that company, to go into business for himself.

BUS LINE IN CHILLICOTHE—R. M. Laird, of Athens, O., has started an Automobile passenger line between Chillicothe and Bainbridge, O., with two large sight-seeing cars capable of carrying twenty passengers.

HAYNES HOLDS CONVENTION—On June 19 and 20 the Haynes Automobile Co., Kokomo, Ind., will hold a convention at that city, the attendance consisting of advertising men, dealers and the prominent officials in the factory.

FORD'S ST. PAUL SERVICE STATION—Work has begun on the new Ford Motor Co.'s service station and salesroom at St. Peter street and University avenue, St. Paul, Minn. The building is to be three-story and concrete.

NEW BIRMINGHAM PARKING RULES—No vehicle is to be allowed to stand more than 20 minutes in the business district at Birmingham, Ala. This ruling is aimed principally at the parking of automobiles. Special policemen will see that the time limit is observed promptly.

ST. LOUIS TRUCK GARAGE—A garage for motor trucks, the first in St. Louis, Mo., is being erected in connection with the new building of the General Motors Truck Co. Space for forty trucks will be provided and entrance made so commodious that a 5-ton truck can enter without backing.

FRANKLIN'S BOSTON BUILDING—Work has been started on a three-story building on Commonwealth avenue, Boston, Mass., at the corner of Cummington street, which will be occupied by the Franklin Motor Car Co., Syracuse, N. Y. It is expected that the building will be ready for occupancy about the first of October.

DOUBLE-DECKERS FOR LOS ANGELES—The Pacific Motor Coach Co. recently placed an order for twenty-two Kelly-Springfield trucks with double-deck coach equipment in service in competition with the Pacific electric cars in Los Angeles, Cal. A 15-minute service will be inaugurated between Los Angeles and Venice and Los Angeles and Pasadena.

AUTOMOBILE BUSES IN TORONTO—The Board of Control of Toronto, Ont., has referred to the city solicitor the application for a franchise of a company to run motor buses on specified routes on the streets of Toronto. The agreement provides for the annual payment to the city of $500 per mile of street used on the routes up to the amount of $30,000.

LOWELL PAYS FOR APPARATUS—The controversy over the Knox fire automobile that was ordered for Lowell, Mass., fire department has been settled by the payment of the bill for the machine. Considerable politics were mixed up in the purchase of the machine, and before the trouble was settled the court was asked to rule upon the Lowell system of purchasing supplies.

NEW U. S. TIRE BUILDING—The United States Tire Co. has leased the lot of ground 5935 Baum Boulevard, Pittsburgh, Pa., and has broken ground for a new two-story and basement brick building, which it will use exclusively as a service station for its solid motor tire department. When finished the new building can accommodate eight motor trucks. A truck can be run into the building in the evening after the truck has finished its day's work and new tires can be applied and ready for service the following morning.

PIERCE-ARROW'S NEW RIM—The Pierce-Arrow Motor Car Co., Buffalo, N. Y., has developed a modified Pierce-Arrow-Johnson demountable rim of the quick-detachable type. Besides being of 10 pounds lighter channel than the previous type, the removable flange ring is fitted with an original form of locking device. This consists of a removable key-piece having its ends shaped to dove-tail with the ends of the flange ring, drawing them together and downward into the slot which is rolled in the rim. While the factory is now well advanced in the production of parts for the new model pleasure cars, considerable effort is also being devoted to a new commercial model that is to make its appearance in due season.

CARRYING SERVICE IN FLORENCE—There are two motor-bus lines in Florence, Italy, both of which are operated during the day only. One of these lines operates three motor buses having a capacity of thirteen passengers each, and the full length of the line is about 1 mile. A 15-minute service is in operation, and the fare charged is 2 cents per passenger. The buses are supplied by the Fiat Co., 18 to 24 horsepower, and cost about $3,250 each. The drivers receive 80 cents and the conductors 60 cents per day. The other line, which is a suburban line, 6 miles long, runs six trips per day with one bus, which is a Fiat, with a seating capacity of fourteen passengers. The fares are as follows: To Trespiano, 4.3 miles, 30 cents; to Pratolina, 6.2 miles, 40 cents. The cost of the bus was about $4,000. The driver receives $1.20 and the conductor 68 cents per day.

MEXICO'S GOVERNMENT AUTOMOBILES.—Objection has been raised to the number of automobiles kept by the Mexican government for the use of its officials. Fifty-one cars are maintained at public expense at the government offices in the capital. The cars represent a total investment of $255,000. The annual maintenance charges are estimated at $232,642. This includes the salary of the chauffeur and generally a footman. Of this number twenty-two are Packards, sixteen are Protos, seven are Fiats, five are Cadillacs and one is a Buick. This is exclusive of the cars owned by the government and assigned to military work. A number of pleasure cars are used to patrol the roads of the Federal District, while most of the higher officers in the field are using motor cars. While many of the latter are rented, the government pays the charges as well as the cost of upkeep. Altogether the Mexican government's annual bill for automobile upkeep is well over half a million dollars.

Institution of Automobile Engineers, assembled before the office of the Ferro Mfg. Co., Cleveland, O.

MACDONALD RESIGNS FROM RUSSELL—K. B. MacDonald, who for the past 2 years has been factory manager of the Russell Motor Car Co., Ltd., at West Toronto, Ont., makers of Russell-Knight cars, has severed his connection with that company.

INVENTS NEW WHEEL MACHINE—Carl D. Fisher, Jr., of Wapakeneta, is the inventor of a machine which he claims will expediate the assembling of automobile wheels by means of large air pressure. The machine weighs 12,000 pounds and has been thoroughly tested, according to the inventor.

ELKHART WANTS APPARATUS BIDS.—The board of public works of Elkhart, Ind., will receive bids for motor apparatus to replace the three-horse truck now in use. It is estimated by the board that the installation of an automobile apparatus will be a saving of at least $2,500 a year to the city.

BUSINESS ENLARGED—The firm of Edwards and Dickey, proprietors of the big Rockingham garage on Vaughan street, Portsmouth, N. H., with C. E. Hoyt, have purchased the Beacham garage business in that city also, and the 5-year lease it had on its quarters, and will conduct both places under one management.

WHITE BRANCH MOVES—The branch of the White Automobile Co. at Providence, R. I., has been moved into a new home on Broad street near Beacon avenue, formerly the headquarters of the Oldsmobile, and which several other dealers were seeking. The old quarters on Cranston street will be used as a service station.

MILWAUKEE WANTS FIRE APPARATUS—The Milwaukee, Wis., common council committee on fire department has recommended the purchase of motor-propelled apparatus costing $41,000. The purchase will consist of three combination hose, chemical, ladder and passenger cars, one tractor for ladder truck or steam fire engine, and three light delivery cars for the supply and repair department. Thomas A. Clancy is chief.

Recent Incorporations in the Automobile Field

AUTOMOBILES AND PARTS

BAYPORT, N. Y.—W. L. Mantha Co.; capital, $1,000; to deal in automobiles. Incorporators: W. L. Mantha, N. F. Mantha.

BELLEFONTE, PA.—Bellefonte Automobile Mfg. Co.; to manufacture automobiles. Incorporators: F. Beakley, W. P. Sieg, E. A. Parrish.

BOSTON, MASS.—Britton-Stevens Motors Corp.; capital, $50,000; to deal in automobiles. Incorporators: W. H. Britton, G. D. Stevens.

CHICAGO, ILL.—Chicago Universal Motor Truck Co.; capital, $10,000; to deal in motor trucks. Incorporators: E. C. Rockwell, J. H. Dunn, C. M. Stevens.

CHICAGO, ILL.—Gloor Motor Truck Co.; capital, $25,000; to manufacture trucks. Incorporators: J. T. Devers, H. L. O'Meara, J. N. Chapman.

CHICAGO, ILL.—Krickwell Motor Co.; capital, $2,500; to deal in automobiles. Incorporators: C. W. Krick, William Capesius, H. L. Strohm.

CINCINNATI, O.—G. A. Schacht Motor & Truck Co.; capital, $35,000; to manufacture and deal in automobiles. Incorporators: Gustac Schacht, William Schacht, Charles R. Talbott, T. C. Jung, M. L. Buchwalter.

CLEVELAND, O.—Auto Carriage Co.; capital, $10,000; to deal in automobiles. Incorporators: A. E. Bernsteen, E. B. Zwirk, Samuel Solker, M. L. Bernsteen, J. Nungesser.

HAVERHILL, MASS.—Mansur Motor Truck Co.; capital, $30,000; to deal in motor trucks. Incorporators: G. B. Mansur, K. L. Moses, N. L. Furbush.

INDIANAPOLIS, IND.—American Automobile Exchange; capital, $25,000; to deal in automobiles. Incorporators: Wilbur Wynant, W. R. Luke, E. C. Brennan.

LOS ANGELES, CAL.—Mehler Motor Car Sales Co.; capital, $5,000; to deal in automobiles. Incorporators: R. W. Mehler, J. J. Bacigalupi, P. Borden, D. L. Jones.

LOS ANGELES, CAL.—Mission Automobile and Realty Co.; capital, $10,000; to deal in automobiles. Incorporators: N. Ledgerwood, J. R. Matthews, I. S. Isenogle.

LOS ANGELES, CAL.—Pacific Auto Truck Mfg. Co.; capital, $250,000; to manufacture motor trucks. Incorporators: W. S. Wheaton, A. J. Pederson, D. M. Carroll, Ellis G. Brode, W. R. Swartwood.

MONTCLAIR, N. J.—Heyer Auto Supply Co.; capital, $25,000; to do a general automobile business. Incorporators: A. P. Heyer, J. Culvert.

NEW YORK CITY—Herlihy-Scales Co.; capital, $2,500; to deal in automobiles. Incorporators: Dalton Scales, Richard Herlihy, B. A. Judd.

NEW YORK CITY—Insular Service Corp.; capital, $50,000; to deal in automobiles and trucks. Incorporators: F. H. Cox, Theodore Kirby, A. E. Carpenter.

NEW YORK CITY—Lurie Aoto Co.; capital, $1,000; to deal in automobiles. Incorporators: S. S. Rosenberg, I. R. Caplan, C. U. Baeker.

PORT CHESTER, N. Y.—A. B. C. Aotomobile Co.; capital, $1,000; to deal in automobiles. Incorporators: W. D. Sporberg, W. F. Gainey, T. F. J. Connolly.

SALT LAKE CITY, UTAH—Deseret Motor Truck Co.; capital, $50,000; to manufacture and deal in motor trucks. Incorporators: Ira Cole, Domine Burns, J. E. Fleige.

SAN DIEGO, CAL.—Clark-Lilly Motor Car and Machine Co.; capital, $50,000; to deal in automobiles. Incorporators: C. C. Clark, J. T. Lilly, Morris Blinnard.

GARAGES AND ACCESSORIES

BOSTON, MASS.—Oxford Garage Co.; capital, $10,000; to maintain an automobile garage. Incorporators: L. D. Robbins, E. L. Brown, S. B. Ingalls.

BROOKLYN, N. Y.—General Tourist Co.; capital, $25,000; to maintain an accessory store for tourists. Incorporators: S. E. Cooper, N. R. Mancill.

BROOKLYN, N. Y.—Brooklyn Auto Repair Co.; capital, $5,000; to deal in automobiles. Incorporators: L. N. Vause, H. P. Freece, C. V. Mulligan.

BUFFALO, N. Y.—Federal Sales Co.; capital, $10,000; to deal in automobile supplies. Incorporators: C. A. Hahl, J. J. Henry, H. S. Bliss.

CINCINNATI, O.—Motor Sales & Service Co.; capital, $5,000; to operate an automobile business and deal in parts and accessories. Incorporators: J. B. Minor, G. B. Jolly, Carl Lehmann, A. Majoewska, W. W. Helmholtz.

CLEVELAND, O.—Commercial Auto Body & Mfg. Co.; capital, $50,000; to manufacture automobile bodies. Incorporators: M. E. McManus, G. H. Krippenberg, F. L. Fuller, J. H. Orgill, J. E. Matthews.

CLEVELAND, O.—Kouyoumjian Electric & Mfg. Co.; capital, $100,000; to manufacture an electric generator for automobiles which will be a cooling fan and generator combined. Incorporators: Robert Williams, M. L. Long, E. K. Kouyoumjian, B. W. Brockett, C. H. Treach.

CLEVELAND, O.—Lake Shore Auto Cartage Co.; capital, $5,000; to do a general cartage and storage business. Incorporators: C. M. Handy, Charles Malouf, G. J. Klamm, John Nelisse, L. B. Handy.

ELKHART, IND.—Paxson Auto Livery; capital, $10,000; to conduct an automobile livery and baggage transfer business. Incorporators: C. E. Paxson, Samuel Gayman, Clyde Paxson.

FAIRBANKS, IND.—Pogue Garage Co.; capital, $30,000; garage business. Incorporators: James Bradbury, T. Johnson, H. Holmes.

INDIANAPOLIS, IND.—Electric Vehicle Co.; capital, $15,000; to operate a garage.

JACKSONVILLE, FLA.—Southern Tire & Supply Co.; capital, $12,000; to deal in accessories. Incorporators: Sam Dunlap, H. E. Perryman, C. H. Brown.

LOS ANGELES, CAL.—Long Beach Motor Supply Co.; capital, $10,000; to deal in accessories. Incorporators: R. F. Ingold, S. D. Weil, Edward Cooper.

MOBILE, ALA.—Hillman Taxi Service Co.; capital, $2,000; to maintain an automobile taxicab business. Incorporators: G. D. Hillman, M. F. Hillman, Rosina Hillman.

NEW YORK CITY—Alhambra Auto Painting and Trimming Co.; capital, $1,050; to paint automobiles. Incorporators: Adolph Horenstein, Max Marcus, Herman Marcus.

NEW YORK CITY—A. & N. Automobile Co.; capital, $1,000; to manufacture an automobile gas starter. Incorporators: E. C. Allison, H. B. Newins, I. M. Highbee.

NEW YORK CITY—Century Garage Corp.; capital, $1,000; to maintain an automobile garage. Incorporators: Moses Lampert, A. R. Martin, A. M. Martin.

NEW YORK CITY—Convent Garage Inc.; capital, $5,000; garage business. Incorporators: E. F. Dannemann, H. F. Dannemann, W. G. Dannemann.

NEW YORK CITY—Drenco Garage Inc.; capital, $10,000; to maintain an automobile garage. Incorporators: D. W. Driscoll, J. A. Rennie, C. Coen.

NORFOLK, VA.—Grent Garage Corp.; capital, $10,000; to maintain an automobile garage. Incorporators: W. H. Bell, A. B. Court, Julian Osborne.

PHILADELPHIA, PA.—Western Tire Co.; capital, $10,000; to deal in automobile tires.

MILWAUKEE, WIS.—Milwaukee Forge & Machine Co.; capital, $8,000; to repair automobiles. Incorporators: G. B. Pillar, A. W. Peffer, John Eckert, Charles Hartson.

SPRINGFIELD, ILL.—Springfield North End Auto Repairing and Vulcanizing Co.; capital, $2,500; to maintain an automobile garage. Incorporators: R. J. Marquardt, C. H. Hamann, Elizabeth Hamann.

TOLEDO, O.—Babcock Garage Co.; capital, $10,000; to maintain an automobile garage. Incorporators: Alonzo G. Duer, C. Wagenhausen, L. P. Wagenhausen.

CHANGES OF NAME AND CAPITAL

CHICAGO, ILL.—John Kelly & Sons; change of name to the Kelly Automobile Co.

CLEVELAND, O.—Bayne-Subers Tire & Rubber Co.; capital increased from $250,000 to $1,500,000.

CLEVELAND, O.—Bayne-Subers Tire & Rubber Co.; change of name to the Subers Fabric Co.

CLEVELAND, O.—Pharis Tire & Rubber Co.; capital increased to $50,000.

LOUDENVILLE, O.—Ohio Grease Lubricant Co.; change of name to the Ohio Grease Co.

ST. LOUIS, MO.—Brown Automobile Co.; change of name to the Peerless Motor Car Sales Co.

Trade Opportunities for American Cars

American Automobile Products Popular in Foreign Trade Centers—Dealers Anxious to Open Trade in Our Cars—Bus Lines Started

REPORTS from American consular officers show that the automobile and its accessories from this country are gradually getting a firm foothold in foreign lands. There is a call for electrics and motor trucks. The performance of the low-priced cars has been so good that there is quite a demand now by dealers in small cars who see a great future in the trade of such makes.

Electrical Supplies—In response to an inquiry from the United States, an American consul in the United Kingdom has forwarded catalogues and pamphlets showing the various styles of electrical supplies sold in his district. Several dealers in electrical specialties who were interviewed stated that the usual procedure is to purchase their stocks from large wholesale traders of representatives of manufacturers in London and other cities who call and solicit orders, but that practice would not deter them from purchasing direct from American manufacturers if the advantages could be shown to them. The names of three firms desirous of getting in touch with American manufacturers may be had on application to the Bureau of Foreign and Domestic Commerce. The complete report submitted by the consul, as well as the catalogues and other pamphlets forwarded, will be sent to interesed manufacturers. File No. 10989.

Motor Trucks—A motor traction company is being formed in a foreign city to handle and transport the cotton, coal, iron, machinery, and other heavy merchandise which forms an important part of the trade of the port, as it is thought the use of motor trucks will greatly expedite the supplies to the mills and the delivery of finished goods at the docks. It is proposed to commence with twenty-five motor trucks, ranging in carrying capacity from 3 to 10 tons. A number of the cars will be of automatic discharge and others will be equipped with self-contained winches for loading purposes. It is thought that most of the cars will be purchased in the United States. Further details will be given as soon as the company is organized, but in the meantime it might be well for American manufacturers of motor trucks to get in touch with the consul who furnished this information. File No. 10993.

Automobile Sundries—The Bureau of Foreign and Domestic Commerce is in receipt of a communication from an American firm manufacturing automobiles, stating that its German representative has made known his desire to get in touch with manufacturers of automobile sundries who may desire representation in Europe. The American firm writes that this representative has disposed of a number of cars for it. File No. 10775.

Automobiles and Motorcycles—A report from an American consular officer in Canada states that a local merchant of good standing is considering the purchase of an inexpensive runabout type of automobile or a first-class motorcycle. Interested American manufacturers may send their catalogues and price lists in duplicate to the consular officer in question, and one set will be handed to the intending purchaser, the other to be retained in his files for the information of any other inquirers. File No. 11131.

Automobile—An American consular officer in a European country reports that a resident of his district is in the market for an American automobile seating five persons, with a speed of 60 miles an hour, not less than 40 horsepower, of the latest design, with self-starter, electric lights, etc. Correspondence with the inquirer should be in German or French. File No. 11116. Address all communications to the Bureau of Foreign and Domestic Commerce, Washington, D. C.

Automobiles and Agricultural Machinery—An American consular officer in Western Europe reports that a business man in his district desires to enter into relations with American manufacturers of automobiles and agricultural machinery not already represented in that district. Correspondence should be in French. File No. 11107.

Electric Automobiles—An American consul in a European country reporting on the market for electric automobiles in his district states that two local business men, one of whom is agent for an American automobile, are interested in receiving offers and catalogues from American manufacturers of very cheap and light American electric cars which could be sold to the public at about $1,500. File No. 10762.

Automobiles—A report from an American consul in India states that a local motor-car company would like to obtain the agency of a light American automobile, four-seated, 4-cylinder, which completely equipped could be sold at retail for about $1,000. Catalogues, prices, and terms c.i.f. should be sent to the inquirer. File No. 11022.

Automobiles for War Use—The Ministry of War in a foreign country has appropriated $40,000 for the purchase of automobiles for the use of the local army. An American consul has forwarded the name of a business man from whom plans, prices, catalogues, etc., showing the class of machines manufactured for war purposes can be obtained. File No. 11014.

Automobile Chassis—A number of foreign dealers in motor cars, anticipating an increase in the customs tariff, desire to form prompt connections with manufacturers who are prepared to supply the chassis only. They propose to build the bodies and assemble the parts locally. Manufacturers of motor-car chassis, as well as of accessories, are requested to supply an American consular officer with about 1 dozen catalogues each, which will be turned over to the proper persons. In each case the prices f.o.b. New York, together with trade and cash discounts to dealers, and approximate weights and measurements, should accompany the catalogues. File No 10939.

Motor Buses—An American consul states that a syndicate has subscribed $125,000 and will purchase 200 motor buses this year and 350 during 1914. Some of the machines will be double deckers. File No. 11,085.

Automobile—A wealthy resident in a foreign country desires to receive catalogs and price lists of American automobiles. He has been favorably impressed with the performance of machinery and other articles of American manufacture, so there is no prejudice to overcome. File No. 11,086.

Automobile Tops—A carriage manufacturer in a city in Europe making a specialty of repairing automobiles has informed an American consulate that he desires to obtain American material used in covering automobile tops. He asks that American houses corresponding with him send samples and price lists. He is also interested in paints, oils and varnishes used in renovating automobiles. Correspondence in Russian, German or French is preferred. File No. 11,092.

Accessories for the Automobilist

SPRING Leaf Lubricator—In these days when the automobilist insists upon the utmost silence in the motor car which he drives, spring squeaks, no matter how small, are not to be tolerated. Besides, when the leaves of the springs become rusted and stick together, some of the car's resiliency is lost, because the springs become in effect the same as solid pieces of steel. But to eliminate these spring troubles in the usual way, driving a cold chisel between the leaves with a hammer, after the car has been jacked up to relieve the tension from the spring upon which the work is being performed, is no easy matter, and has the disadvantage of possible marring of the spring due to the application of the chisel and false hammer blows.

To eliminate these troubles and even the necessity for jacking up the car in order to spread the leaves to be oiled, the Spring Leaf Lubricator Co., Ann Arbor, Mich., has devised a special tool for spring doctoring. This devise consists of a simple, drop-forged clamp, Fig. 1, the jaws of which are provided with wedges for forcing in between the leaves. Fig 2 shows the method of application and one of the leaves spread for the insertion of oil.

The lubricator is made with sufficient width between its jaws for application to the widest passenger car springs now in use. For trucks, a heavier type is made which will accomodate the widest of commercial car springs. The only difference between the two types is that the latter is provided with a handle which is free to move in the hole in the end of the screw so as to afford the greater leverage necessary for spreading of the heavier truck springs.

Besides its usefulness as a leaf spreading device, the tool may be utilized as a repair clamp for clamping broken springs temporarily until they can be repaired. This application is shown in Fig. 3.

Hoffecker Electric Odometer—The Hoffecker Co., Boston, is making deliveries to builders of electric passenger cars of its electric odometer, Fig. 4, which resembles a speedometer, excepting in that it measures distances traveled, these being registered on a circular dial the same as speeds of travel are indicated on a speedometer. The dial reads to 100 miles, the reason being that the capacity of battery on one charge is generally lower than this. In the bottom of the dial space is a season odometer for 100,000 miles.

This instrument, being the first of its kind to be marketed, is a neat one, with a 3-inch dial, which is of black enamel with white letters and a white pointer or indicator hand. The bezel or casing for it is mounted on a small circular bracket screwed to the dash, the bezel threading into a socket in the center of the bracket. The casing is finished in black enamel and is 1.6875 inches thick.

The odometer mechanism is driven through a flexible shafting of standard Hoffecker construction and made up of seventeen strands of flexible piano wire. The gearing between the shaft and the road wheels is such that the shaft makes 180 revolutions per mile. As many electrics use solid rubber tires exclusively, the shafting has been mounted to not be influenced by the additional vibration.

The Hoffecker Co. is now marketing its combined speedometer-odometer and timepiece all mounted on a special oblong-shaped dash bracket 10.25 inches in length. All three of the instruments are made with a 3-inch dial, the small diameter of these being the reason for mounting the speedometer in one bezel without anything else, and the odometer with its trip and season recorders in a separate bezel. The trip odometer reading to 100 miles has the figures in a circle around the dial, with tenths and hundredths shown at each side the hand pivot and the 100,000-mile season odometer in the 6 o'clock position. Between the odometer and speedometer bezels are two buttons, the lower one a release and the top one a reset button for the odometer. The flexible shaft drive is connected horizontally at the right end from which point it is intended to be carried horizontally to the side of the body. The bezel of each instrument is finished in white nickel and carries a black porcelain dial with white enamel letters. The time piece is an 8-day Waltham movement.

Koenig's Portable Extension Battery Support—M. Koenig, chief engineer of the Central Brewing Co., New York City, has invented a most practical appliance for users of electric trucks. This device, Fig. 5, page 1286, is a portable extension battery support. It can be made to fit any truck or battery and is simple as well as effective. This support is put on in about a half a minute by simply placing two rods, extending from each end of the support, upon the channel frame, and then tightening a turnbuckle on each. There is a small extension on each end of the support, which is buckled to the battery cradle to keep the cradle from coming out when the battery is slid out for examination. The end of this extension is threaded so as to permit a variable adjustment. This battery support can be carried with the truck, which enables the driver to examine the battery with little effort.

Golden Glow Headlights—The Esterline Co., Indianapolis, Ind., is now marketing a new kind of headlight, being known as the Golden Glow, Fig. 6, on account of the peculiar light obtained with it. The latter is caused by the use of the special reflector, prepared as follows: The glass used for the reflector is shaped as a true parabola and ground to high brilliancy on both surfaces. After this has been done the surface is silvered with a relatively heavy plating and then covered with an electrolytic deposit of copper. The result is a red surface backed by silvery white, which practically equals the color of metallic gold. Due to this color, the reflector emanates a golden light instead of the whitish brilliancy produced by the incandescent bulb, and it is claimed that this light, while fully as penetrating as the white, lacks the painful quality of glaring white light. Incidentally, the claim is made by the manufacturer that the yellow light is

Vol. XXVIII NEW YORK—THURSDAY, JUNE 26, 1913—CHICAGO No. 26

The AUTOMOBILE

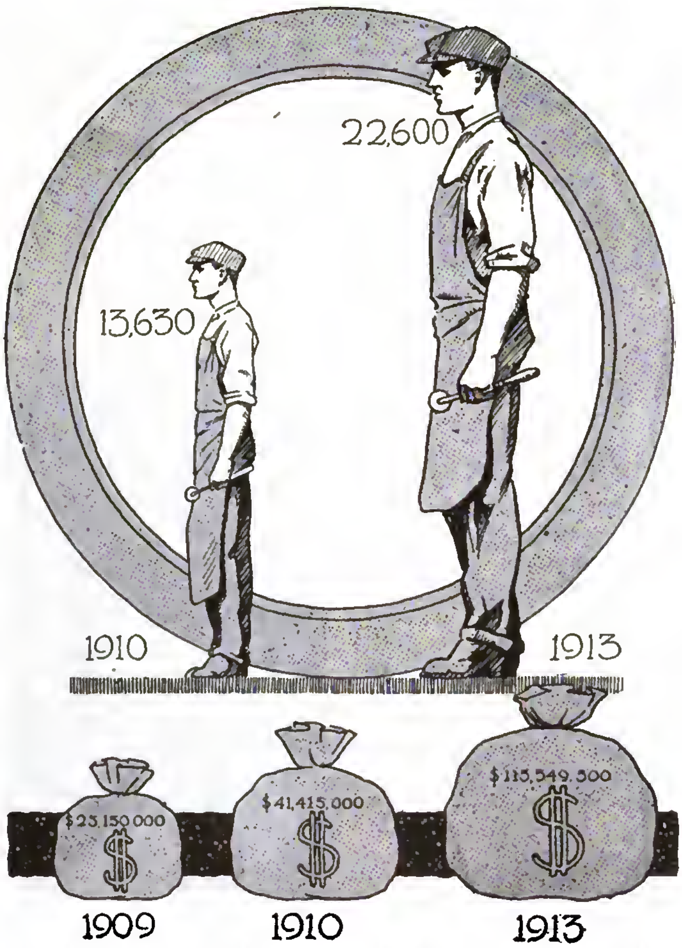
Where 20,000 Tires Are Made Daily

By L. V. Spencer

AKRON, the foremost city of the world in the production of rubber goods, gives to the automobile public 20,000 tires each day. It turns out in every 24 hours more pneumatic and solid motor vehicle tires than all the rest of the United States combined.

Considering that the average diameter of these tires is 34 inches, that is, taking into account all the different sizes, if a day's output of the Akron factories were arranged in a long line so that each tire would be tangent to both the one in front of it and the one behind—and here the statistician gets in his work—the line would measure nearly 12 miles in length. Or, going a step farther, and figuring on this production for a year of 300 working days, the line would have a length of 3,400 miles, or more than the distance across the American continent by about 1,000 miles.

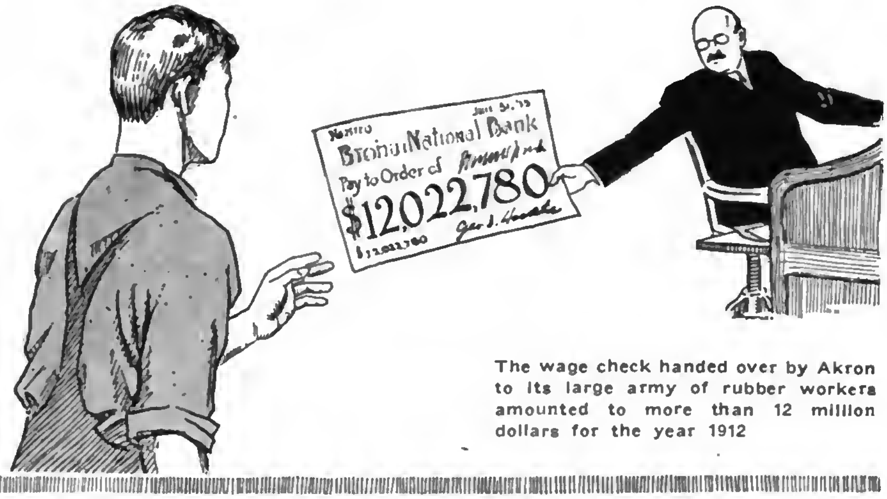
It is hard to realize that there is is a demand for such an enormous quantity of tires as that produced in Akron alone, not to mention the outputs of many other very large tire manufactories throughout the United States. Yet several of the Akron factories are laying plans for further additions to the tire-making divisions of their plants so as to materially increase their outputs. It is rather difficult to see where such enormous production will end.



Upper diagram shows enormous increase in Akron's rubber workers in 3 years. Below, total capitalization of rubber factories in Akron for 1909, 1910 and 1913. Note great increase made last year

For the making of this great line of tires, besides the daily production of an enormous quantity of mechanical rubber goods, hard rubber specialties and every other conceivable class of merchandise made of rubber, one-third of the world's total production of crude rubber finds its way to Akron, giving this thriving city of Northern Ohio a unique position in the industrial world.

Just as Detroit is looked upon as the Mecca of the makers of automobiles and their parts, as Minneapolis is noted for its flour mills, as Sheffield is linked with steel, so Akron is known the world over as the rubber goods city. Many a rubber man in far-away Ceylon or in South America knows little or nothing of the cities of the United States, but, nevertheless, the name of Akron is at his tongue's end. To him it is well nigh synonymous with his trade with the Great United States.



The wage check handed over by Akron to its large army of rubber workers amounted to more than 12 million dollars for the year 1912

There are few who have not actually visited these great rubber goods making institutions who realize the enormous scale upon which they are built. The Goodyear factory, for instance, offers employment to about 6,000 men, has a daily capacity of 6,000 automobile tires in addition to its many other lines of manufacture and has 2,000,000 square feet of floor-space. Some statistician has figured out that if the Goodyear factory were 50 feet wide and one story in height, it would be over 8 miles long.

The Firestone company is housed in the largest single rubber manufacturing building in the world. This plant covers 15 acres and gives employment to 3,500 persons. It produces 50 tons of finished tires each day.

While the rubber industry has been the chief business of Akron for a number of years, it is only within the past 10 years that it has had any remarkable growth. Although the making of tires is only one branch of the rubber-making industry of Akron, it is clear that the rapid strides which the factories have made and the proportionate increase of every branch of its commerce which is related to rubber making are due largely to the unprecedented growth of the automobile industry with its consequent demand for an enormous number of pneumatic and solid tires.

Akron must charge its steady growth and present prosperity to the automobile industry, just as Detroit has done. Ten years ago the B. F. Goodrich Co. and the Diamond Rubber Co., now combined, were the only companies turning out automobile tires in Akron. Their output was only a few hundred a day at that time. The other large rubber concerns which now have a large daily production were then not doing any automobile tire business at all. But the greatest development in the motor vehicle tire business in Akron has been within the last 5 years in parallel with the giant strides made in the production of automobiles during the last few years.

Industry Began in 1869

Forty-four years ago the rubber industry in Akron was begun. In 1869 Dr. B. F. Goodrich established a small plant for the manufacture of rubber products which was the nucleus for the present great combine which bears his name. The first building measured 40 by 100 feet, and the doctor's company was capitalized at $100,000. Little did the genial doctor dream that in less than 50 years his company would have a factory giving employment to nearly 15,000 workers and having a floor-space of about 65 acres. The present capitalization of the Goodrich combine is $90,000,000, and it manufactures about 10,000 tires daily.

Dr. Goodrich's first plant employed 25 persons. In the early days he is said to have been his own factory manager, chief engineer, chemist and traveling salesman. For several years he alternately journeyed around the country taking orders and returned to his little factory to personally see that they were filled. None of the original buildings now remains.

Since then other great rubber factories have sprung up within the city, gradually and surely advancing the small community which in Dr. Goodrich's time had a population of about 10,000 to the present thriving industrial city of 90,000 people.

There are at the present time in Akron eighteen rubber factories as against fourteen in 1909 and fifteen in 1910. These eighteen plants, having an aggregate capitalization of $113,549,500, are listed:

American Hard Rubber Co.
American Tire and Rubber Co.
Buckeye Rubber Co.
Federal Waterproofing Co.
Firestone Tire and Rubber Co.
B. F. Goodrich Co.
Goodyear Tire and Rubber Co.
Gregory Rubber Co.
Hadfield Rubber Co.
Lion Rubber Co.
Miller Rubber Co.
Mohawk Rubber Co.
Motz Tire and Rubber Co.
O'Neill Tire Protector Co.
Philadelphia Rubber Works Co.
Portage Rubber Co.
Starr Rubber Co.
Swinehart Tire and Rubber Co.

Then there is the Swinehart plant, which is turning out in the neighborhood of 10 tons of solid tires and from 300 to 500 pneumatics daily. In this plant there are 300 employees. An addition is now under way which will double the Swinehart plant in size and make it possible to increase the production of tires about three-fold.

The Miller Rubber Co. furnishes employment to 1,200, and has a pneumatic tire output of 1,000 a day. Seven hundred of its employees are connected with the production of tires, while the others are concerned with the making of rubber automobile accessories and various other rubber products. No solid tires are made by this concern. The floor-space of the Miller plant is 200,000 square feet.

In the Buckeye plant of the Kelly-Springfield Tire Co. we find about 550 men engaged in the making of 500 tires and a like number of inner tubes each day. Several new buildings are under way at the present time, and the company plans to increase its tire output this fall to 1,200 daily.

An extensive plant dealing exclusively with the manufacture of solid tires is that of the Motz Tire and Rubber Co. This company turns out a large number of special solid cushion tires particularly adapted for use on electric vehicles. Recently some improvements have been made in these tires.

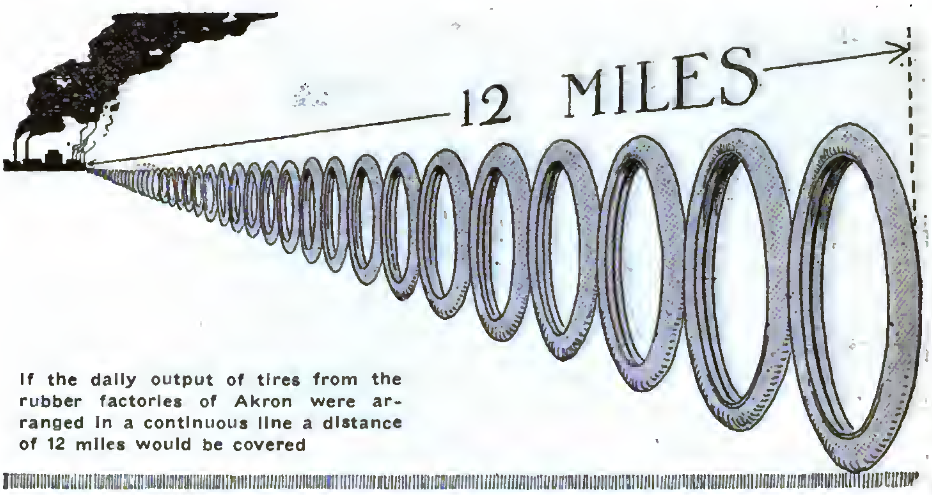
The Mohawk Rubber Co., which about 90 days ago took over the plant of the Stein Double Cushion Tire Co. and remodeled it, is making passenger car tires exclusively. It turns out 150 casings and 500 tubes per day with 75 employees. The plant extends

View in the tread-laying room of a tire factory over an area of 100,000 square feet.

Another tire maker is the Portage Rubber Co., which turns out 150 pneumatics and 200 tubes each 24 hours. Its workmen number 200, half of whom are in the tire branch, the rest being concerned in the making of mechanical rubber goods.

The American Tire & Rubber Co., with 50 men and a floor-space of 30,000 square feet, manufactures inner tubes, tire accessories and cements, besides a line of mechanical rubber goods.

Then there is the O'Neill Tire and Protector Co., which makes tire protectors, reliners, blow-out patches, air bags, portable vulcanizers and the like. It has a plant of 11,000 square feet and gives employment to twenty-four persons.



If the daily output of tires from the rubber factories of Akron were arranged in a continuous line a distance of 12 miles would be covered

The Philadelphia Rubber Works Co. is not in the tire making line, but confines its activities to the manufacture of reclaimed rubber only. Its process for the reclaiming of rubber is exceedingly extensive, and to the plant comes all sorts of rubber scrap. A large proportion of this is worn out tires, the rubber in which, though no longer of value for automobile purposes, nevertheless may be reclaimed for many other uses.

The American Hard Rubber Co., as its name implies, does not make any soft rubber goods whatever, but concentrates on the making of specialties of the hard rubber variety such as battery jars and the like.

Automobile goods are also out of the line of the Federal Waterproofing Co., which specializes on waterproof materials.

The Star Rubber Co. 2 years ago discontinued the making of automobile tires, its factory now being devoted to the production of seamless rubber articles.

The Hadfield Rubber Co. has some products for the automobile trade. These are rubber bumpers, insulators and washers. In addition, it gets out a number of specialties for surgeons' and household use. It employs about a dozen men.

A unique line is that of the Gregory Rubber Co., which is not engaged in the making of any motor car products, but makes rubber specialties and toy balloons, the latter being the larger end of its business by far. For this special line, twenty people are employed and 8,000 square feet of floor space occupied.

The Lyon Rubber Co. is also a specialty concern, making tire repair cements, repair patches and accessories.

In the sundries room, showing arrangement of tire formers

These interesting facts and figures covering Akron's plants will serve to bring home more forcibly to the average reader the extent to which this single industry in a single city has developed.

Last year Akron's eighteen rubber factories had an output valued at $94,445,000, which includes all classes of rubber goods. There are in the city 144 manufacturing concerns inclusive of the rubber factories. These have a total capitalization of $142,356,450 at the present time. Thus it will be seen that these eighteen factories, though being only 11.8 per cent. of the total number of establishments in the city, represent 79.7 per cent. of Akron's total invested capital.

Capitalization Increases Fivefold

This enormous capitalization of the rubber factories, headed by the $90,000,000 Goodrich company, has increased nearly fivefold in the last 4 years, as shown by the following table:

Total Capitalization Akron Rubber Factories

Year	Amount
1909	$25,150,000
1910	41,415,000
1913	113,549,500

An interesting feature of a consideration of any industrial community such as Akron is the number of wage earners and how that large army is provided for in the way of living facilities—always a serious problem. Over one-third of the city's present population is of the wage earning class. Or, to be specific, there are employed in the 144 establishments claiming Akron as their home 34,700 working men and women. Sixty-five per cent. of this number, or 22,600, find employment in the rubber factories, making this single industry responsible for one-quarter of the city's population.

Six Payrolls Average $12,022,780

During 1912, the six largest rubber companies had an average payroll of $12,022,780, a figure close to the aggregate bank deposits in all of the banks of the city on an average day last year. While the rubber workers are by no means all concerned in the making of tires, it is safe to say that about one-quarter of the rubber workers are employed in some operation or other connected with the making of these necessities of automobiling. It is impossible to obtain any figures which segregate the number of tire workers from the total employees in the plants, no statistics being kept along this line, owing to the continually varying conditions.

For similar reasons we are unable to go back more than 3 years for accurate statistics as to the total number of workers. However, in the past 3 years, since the automobile industry began to make such rapid strides and to demand millions of tires each year from the Akron factories, the percentage of increase of rubber workers has been 5.35 per cent. as compared with the total population of the city. The following table, which shows the

The calender room where the rubber stock is passed through the heated rolls of the huge calenders

exact figures for 1910 and 1913 brings out this point strongly:

Year	Total population	Wage earners in rubber factories	Percentage of total population in rubber industry
1910	69,067	13,630	19.75
1913	90,000	22,600	25.10

Thus it is shown that the rubber industry has probably drawn heavily upon other lines of industry in the city within the last few years, and that while these other lines have also grown to help swell the total population, the city's chief industry today gives employment to one-fourth of the people when 3 years ago it paid one-fifth for its services, although in the same period the total number of persons in the city has increased by 30 per cent.

The nature of the rubber manufacturing business and particularly most of the operations in connection with the making of tires requires the services of employees of the skilled class, though it is true that unskilled labor may be utilized for many operations. Piece work schemes seem to predominate in the Akron factories, and on this basis many of the men make good wages of from $4 to $6 each day.

There is practically no other city in the country the size of Akron where the working class has so much money per capita. A general air of prosperity pervades the community.

Erect Houses for Workers

The employers and the civic bodies of the city have not lost sight of the fact that adequate living facilities must be provided for its large industrial army. Additional workingmen's homes are being erected as fast as possible, largely through the endeavors of the Housing Committee of Akron's wide-awake Chamber of Commerce, which has a membership of about 1,200 of the city's leading business men.

There is still a great demand for small houses in the city and the Chamber of Commerce is seeking to interest outside capital along this line by various kinds of publicity. For the fiscal year ending November 1, 1912, the records of the City Building Inspector's office show that 2,372 permits were issued for the erection of houses. This is a rather remarkable showing for a city of this size, but it is believed that a still larger scale of building operations will be recorded this year, due to the rapid growth.

The factories themselves are aiding in the work of providing homes for their men. As a case in point, the Goodyear company has recently purchased a tract of land adjoining its plant where desirable homes are to be built for its employees, the properties being sold to the men on very easy long terms at cost. By this arrangement a man can own his home in from 12 to 15 years.

Besides this, this concern operates a hotel, so called, where newcomers to the city who are employed at the factory may live until they can find a permanent location. They are charged for this only a nominal sum of 15 cents a day for the first week, 20 cents for the second, and so on. This scheme is working very successfully.

These views may seem diametrically opposite to the published reports which were current at the time of the recent strike trouble in the city. That strike probably did more to rid the city of an undesirable element and to clear up misunderstandings between employers and employees than anything else could have done. Today they are closer together than ever before.

Like many another affair of its kind this strike grew from a

Each tire is buffed before the tread is put on

Scene in the curing room where pneumatic tires are given their first vulcanization

small affair until it had spread through the whole body of rubber workers of the city. Certain strike agitators then descended upon the community and made many claims against the Akron employers which were not only unfounded but malicious. It was at the instance of these agitators that the Senate of the State of Ohio sent a committee to Akron for the purpose of actually probing the labor conditions there and to determine just how many of these claims, if any, were true.

In addition to discovering that the strike instigators were advocating a system of sabotage, the committee discovered that their claims were in the main absolutely ungrounded. In its report, the committee further brought out that the testimony of the employers and employees showed that the wages paid by the rubber companies generally compare favorably with those paid in other industries and that the wages paid in the tire-building and tire-finishing departments are evidently higher than those paid in other industries where like skill and effort are required.

The Ohio Senate Committee's findings went further in stating that the buildings of the rubber companies are practically fire-proof, well-lighted and so constructed as to provide good ventilation. And in conclusion it was shown that the investigation has proven profitable and of great value to the rubber manufacturers, the employees and the general public. "The testimony has developed abuses which had crept in and grievances of which the managements of the rubber factories were not aware. Many of those have no doubt already been corrected, all of which is to the advantage of all concerned."

All of this may present the unpleasant circumstance in a different light to many as coming from an unbiased source. Many of the workers did not know what they were striking for. The cloud has completely blown over now; the factories are running with the normal number of operators; production has been put back to its normal. Akron is itself again and the better for its experience.

After cleaning, the tread is applied as shown

Banking Institutions Are Active

Always a criterion by which to judge the prosperity of any community is the activity of its banking institutions. The Akron Chamber of Commerce statistics show that, besides an increase of 89 per cent. in invested capital and 31.4 per cent. in the number of those employed for 1912 over the previous year, the Akron banks also had a prosperous year. The total deposits in all of the banks of the city on November 1, 1912, aggregated $16,648,441, as against $14,717,790 on the same date in 1911, an increase of 13 per cent. The surplus and undivided profits of these institutions also showed an increase of 8 per cent. for this period.

Akron's bank clearings of $93,378,000 for the year 1912 were 43.0 per cent. greater than they were for the previous year. This gain was greater than that of any other city of the Central States, according to the statement of R. G. Dun & Co. This is but another proof of the increasing volume of business which the city enjoys.

Akron, with its advantageous location for trade, its shipping facilities afforded by five railroads, its educational features and its offering of cheap and desirable living conditions for its workmen, has risen to its present proportions logically. The automobile industry is responsible for its rapid growth within the last few years, and just as long as that industry continues to grow, so will Akron advance correspondingly. There is no limit to its possibilities as a commercial center.

Alter Tariff Rate Bill

New Rate on Cars Submitted to Senate Caucus Calls for Duties of 30 To 45 Per Cent.

WASHINGTON, D. C., June 22—The Underwood-Simmons tariff revision bill, as agreed upon by the Democrats of the Senate finance committee, has been submitted to the Democratic caucus of the Senate and yesterday went through a full day's session of the caucus with harmonious support for most of the alterations the Senate finance committee members had made in the original bill. The new rate on motor cars as submitted to the caucus reads as follows:

"Paragraph 121. Finished automobiles, valued at $1,500 or over and automobile bodies, 45 per centum ad valorem; finished automobiles valued at less than $1,500, 30 per centum ad valorem; automobile chassis, and finished parts of automobiles, not including tires, 30 per centum"

Cheap motor cars, as necessaries of business and farming life, were the subject of much of yesterday afternoon's debate in the caucus. The finance committee democrats cut the Underwood rates from 45 per centum to 30 per cent. on motor cars valued at less than $1,500, and in the debate several democratic senators urged a further cut and recommended that the tariff be only 10 or 15 per cent on cars valued at less than $1,000. This demand was made on the ground that cheap motor cars were now commercial necessities.

The caucus did not settle the motor car controversy, but asked Chairman Simmons and his colleagues on the finance committee to investigate further. Advocates of the lower duty claim the government would lose little revenue, as the high-priced machines pay most of the tariff.

J. D. Maxwell To Build Cars

INDIANAPOLIS, IND., June 25—*Special Telegram*—J. D. Maxwell and associates have bought the plant of the T. B. Laycock Mfg. Co. here, for approximately $300,000 and will manufacture automobiles. Manufacturing and selling companies are being formed and forces organized. Details are not available now but a medium-priced car will be built. The plant is 880 feet long and 270 wide and has its own heating, lighting and water plant.

Stepney Motion Denied by Court

NEW YORK CITY, June 20—Motion made by the Stepney Tire & Rubber Co. to combine its countersuit with the suit of the Rutherford Rubber Co. was denied yesterday in Supreme Court, Special Term. The Stepney Tire & Rubber Co. has filed a countersuit of $72,000 against the Rutherford company, alleging breach of contract in supplying poor material. The Rutherford company manufactured tires for the Stepney company to be sold as an unguaranteed product. The latter company states that tires were returned that had not covered 5 miles although the contract stated that the tires were to have the same tread as the regular Rutherford output.

The suit of the Rutherford company is for a little more than $2,000 and is for moulds which they claim the defendants should continue to pay for under the contract. The Stepney company has not been actively in business for the past 2 years, according to Walter Lissberger, former treasurer.

Midland Assets Are Indefinite

MOLINE, ILL., June 21.—An examination of the books of the bankrupt Midland Automobile Co. has been held and shows that the assets of the company could be placed anywhere from $100,000 to $190,000 while the liabilities are approximately $250,000. The cause for the indefiniteness in assets is that most of the equipment is old. Originally it cost slightly over $200,000. An invoice is being made and basis on which settlement will be made with creditors will be announced soon. Edward McCullough of Springfield has been appointed receiver of the defunct company by Judge Humphrey of the federal court at Springfield. Attorney G. A. Shallberg of Moline is representing the creditors of the tri-cities.

Milwaukee Motor Co. Files Petition

MILWAUKEE, WIS., June 23—An involuntary petition in bankruptcy has been filed against the Milwaukee Motor Co., Milwaukee, Wis., by three creditors with claims aggregating about $350,000. They are: Racine Brass & Iron Co. and Standard Foundry Co., Racine, Wis., and the Standard Paper Co., Milwaukee. The petition states that the company has assets of about $350,000 and that its liabilities are about $280,000.

It is alleged that the Milwaukee Motor Co. performed an act of bankruptcy on May 19 in transferring to Ernst G. Miller, of Milwaukee, $25,000 in notes given to the company by the Imperial Motor Car Co., Jackson, Mich., which constituted a preferential payment. The First Savings & Trust Co., Milwaukee, has been appointed trustee under bonds of $10,000.

The past success of the concern, the large number of orders on its books for execution, and the energy behind the company will, it is confidently believed, result in a speedy settlement of the bankruptcy litigation. The plant is being operated at full time and the trustee will continue it in this manner.

Ford Declares $10,000,000 Dividend

DETROIT, MICH., June 24—That a cash dividend of $10,000,000 has been declared by the Ford Motor Car Co. is the report in banking circles of Detroit. It is stated that Mr. Ford, owning 51 per cent. of the stock, will get $5,800,000. James Cousins gets $1,150,000 and Dodge Brothers and the Gray estate get $1,000,000 apiece. Checks for $500,000 go to John W. Anderson and H. H. Rackham. This report comes through Detroit bankers and has not as yet been verified by any offices of the Ford company although the report is accepted here as correct.

Want Board Declared Bankrupt

WASHINGTON, D. C., June 23—A petition that the B. F. Board Truck Co., Alexandria, Va., be declared a bankrupt has been filed by a number of creditors. The petition has been made returnable July 3. The affairs of the company are now in the hands of T. C. Smith as receiver.

BUFFALO, N. Y., June 24—*Special Telegram*—Nathan W. Williams, of Evanston, Ill., began suit today in the United States District Court against the Motor and Manufacturing Co., of Dunkirk, N. Y., alleging infringement of patents. The plaintiff declares that he holds patents for a beating and ventilating system for automobiles and claims they have been infringed.

COLUMBUS, O., June 23.—The new managers of the Columbus Buggy Co., T. C. Dunlap and George W. Lattimer, have started to operate the plant on an aggressive scale. About 150 men are employed at the plant completing the jobs already started under the receiver. Steps are being taken to organize a new company to take over the assets.

Automobile Securities Quotations

Recovery of the rubber stocks is the predominant feature of the market for the past week. Firestone common, which had dropped 32 points during the past 2 weeks, regained 7 and Goodyear picked up 11. Alco preferred took a jump of 10 points while Pope preferred fell off 7 points. Outside of these facts the summer quietude of the market was undisturbed.

Bids Opened for P.O. Cars

Large Number of Bidders on Hand To Secure the Contracts for U. S. Mail Carrying Vehicles

WASHINGTON, D. C., June 21—With a large number of representatives of bidders in attendance, the purchasing agent of the post office department yesterday opened bids for furnishing twenty or more four-wheeled and twenty or more three-wheeled motor driven vehicles for use in the postal service as they may be ordered during the remainder of the fiscal year ending June 30, 1913. The specifications call for four-wheel gasoline and electric cars and three-wheel gasoline and electric machines. The detailed bids were as follows:

The White Co., Cleveland, O., four-wheel gasoline trucks: in lots of five, delivered in 21 days, $2,060 each, equipped with pneumatic or cushion tires, and the same price in lots of ten or more, delivered in 42 or 60 days, with the same type of tire equipment.

General Vehicle Co., Long Island City, N. Y., electric four-wheel cars: in lots of five, with different tire equipment, $2,090, $3,340, $2,865; in lots of ten, $2,690, $3,340, $2,865; in lots of fifteen, $2,020, $3,280, $2,805; in lots of twenty, $2,550, $3,220, $2,745; in lots of twenty or more, $2,480, $3,160, $2,685.

Walker Vehicle Co., Chicago, Ill., four-wheel electric, delivered within 60 days in lots of five, $2,962, $2,362, $2,462, $2,917, $2,317, $2,-417; delivered within 60 days in lots of ten, $2,917, $2,317, $2,417; delivered within 70 days in lots of fifteen, $2,872, $2,272, $2,372; delivered within 90 days in lots of twenty, $2,822, $2,227, $2,327; delivered within 90 days in lots of twenty or more, $2,827, $2,227, $2,327.

Missouri Motor Car Co., St. Louis, Mo., four-wheel gasoline cars: in lots of five, delivered within 30 days, $1,316, $1,350; in lots of ten, delivered within 40 days, $1,303, $1,335; in lots of fifteen, delivered within 50 days, $1,290, $1,325; in lots of twenty, delivered within 60 days, $1,277 $1,310; in lots of twenty or more, delivered within 90 days, $1,265, $1,300; three-wheel gasoline cars: in lots of five, $780, $805; in lots of ten, $772, $800; in lots of fifteen, $765, $790; in lots of twenty, $758, $785; in lots of twenty or more, $750, $780.

Ward Motor Vehicle Co., New York City, four-wheel electric cars: in lots of five, delivered within 60 days, $2,275.25, $2,037.35; delivered within 90 days, in lots of ten, $2,215.38, $1,984.13; in lots of fifteen, delivered within 90 days, $2,155.50, $1,930.50; delivered in 120 days, in lots of twenty, $2,095.63, $1,876.88; in lots of twenty or more, $2,035.75, $1,-823.75.

Atlantic Vehicle Co., Newark, N. J., four-wheel electric cars: in lots of five, delivered in 45 days, $2,350, $2,660, $3,100; in lots of ten, delivered within 50 days, $2,325, $2,550, $3,050; in lots of fifteen, delivered within 60 days, $2,270, $2,500, $3,000; in lots of twenty or more, delivered within 90 days, $2,200, $2,400, $2,950.

Baker Motor Vehicle Co., Cleveland, O., all deliveries within 60 days: in lots of five, $2,350, $2,280; in lots of ten, $2,280, $2,255; in lots of fifteen, $2,255, $2,230; in lots of twenty, $2,230, $2,205; in lots of twenty or more, $2,230, $2,205.

Mac-Carr Co., Allentown, Pa., four-wheel gasoline cars: in lots of five, delivered within 30 days, $1,500 for both pneumatic or cushion tires; in lots of ten, delivered within 45 days, $1,475; in lots of fifteen, delivered within 60 days $1,450; in lots of twenty, delivered within 75 days, $1,425; in lots of twenty or more, delivered within 90 days, $1,400.

Kissel Motor Car Co., Hartford, Wis., four-wheel gasoline cars: in lots of five, delivered within 40 days, $1,550, $1,610; in lots of ten, delivered within 60 days, $1,475, $1,535; in lots of fifteen, delivered within 75 days, $1,475, $1,535; in lots of twenty or more than twenty, delivered in 75 and 120 days respectively, $1,475, $1,535.

Brockway Motor Truck Co., Cortland, N. Y., four-wheel gasoline cars: with cushion tires: delivered in lots of five, $1,700; lots of ten, $1,650; lots of fifteen, $1,625; lots of twenty, $1,600; lots of twenty or more, $1,600; deliveries are in 60, 90 and 120 days.

Waverley Co., Indianapolis, Ind., four-wheel electric cars: in lots of five, delivered within 70 days, $1,820; in lots of ten, delivered within 85 days, $1,780; in lots of fifteen, delivered within 100 days, $1,755; in lots of twenty, delivered within 110 days, $1,735; in lots of twenty or more, delivered within 110 days at the rate of two per week, $1,725.

W. H. McIntyre Co., Auburn, Ind., four-wheel gasoline cars: in lots of five, delivered within 60 days, $1,735, $1,675; in lots of ten, delivered within 70 days, $1,730, $1,700; in lots of fifteen, delivered within 80 days, $1,682.95, $1,624.75; in lots of twenty, delivered within 90 days, $1,648.25, $1,591.25.

Kelsey Motor Co., Hartford, Conn., three-wheel gasoline cars: in lots of five to twenty, and twenty or more, deliveries within 90 days, $800 and $850.

Buffalo Electric Vehicle Co., Buffalo, N. Y., four-wheel electric cars, $1,890, $1,885, $1,880, $1,875, $1,868, $1,860, $1,855, $1,850.

Lippard-Stewart Motor Co., Buffalo, N. Y., four-wheel gasoline cars: in lots of five delivered within 60 days, $1,752.57, $1,692.59; in lots of ten, delivered within 70 days, $1,722.59, $1,692.59; in lots of fifteen, delivered within 75 days, $1,722.59, $1,692.59; in lots of twenty, or more, delivered within 80 days, $1,722.59, $1,692.59.

Public Service Motor Co., New York City, four-wheel electric car: in lots of five, delivered within 15 days, $1,660 for either pneumatic or cushion tire equipment; in lots of ten, delivery within 60 days, $1,620; lots of fifteen, delivery within 70 days, $1,580; in lots of twenty, delivery within 80 days, $1,540; lots of twenty or more, delivery within 100 days, $1,540.

Brown Commercial Car Co., Peru, Ind., four-wheel gasoline cars: in lots of five, delivery, 10 days, $1,650; L, 900; lots of 10, delivery, 20 days, $1,500, $1,750; lots of fifteen, delivery, 30 days, $1,490, $1,740; lots of twenty, delivery, 40 days, $1,450, $1,700; lots of twenty or more, delivery 40 days, $1,420, $1,670.

Atterbury Motor Car Co., Buffalo, N. Y., four-wheel gasoline cars: in lots of five, delivered within 45 days, $1,760 for either pneumatic or cushion type of tires; in lots of ten, delivery, 60 days, $1,742; lots of fifteen, delivery, 75 days, $1,724.80; lots of twenty, delivery, 90 days, $1,707.20; lots of twenty or more, delivery 90 days, $1,672.

Palmer-Moore Co., Syracuse, N. Y., four-wheel gasoline cars: ten, $1,125.

Argo Electric Vehicle Co., Saginaw, Mich., four-wheel electric cars: lots of five, delivery, 60 days, $1,750, $1,825; lots of ten, delivery, 75 days, $1,725, $1,800; lots of fifteen, delivery, 90 days, $1,700, $1,775; lots of twenty or more, delivery, 90 days, $1,700, $1,775.

Durant-Dort Carriage Co., Flint, Mich., four-wheel gasoline cars: lots of five, delivery, 60 days, $1,550, $1,575; lots of ten, delivery, 60 days, $1,453.50, $1,487.50; lots of fifteen, delivery, 60 days, $1,453.50, $1,487.50; lots of twenty, delivery, 60 days, $1,868, $1,400; lots of twenty or more, delivery, 60 days, $1,368; $1,400.

Commercial Truck Co. of America, Philadelphia, Pa., four-wheel electric cars: lots of five, delivery, 60 days, $2,170, $2,310; lots of ten, delivery, 60 days, $2,130, $2,270; lots of fifteen, delivery, 90 days, $2,065, $2,220; lots of 20, delivery, 90 days, $2,045, $2,185; lots of twenty or more, delivery, 90 days, $2,045, $2,185.

Harley-Davidson Motor Co., Milwaukee, Wis., three-wheel gasoline cars: lots of five, delivery in 60 days, $425; lots of ten, $425; lots of fifteen, delivery, 90 days, $403; lots of twenty or more, delivery, 90 days, $403.

Utility Car Co., New York City, three-wheel gasoline cars: in lots of five to twenty or more, delivery within 60 days, $500.

National Contracting Co., New York City four-wheel M. C. electric: lots of five, delivery, 20 days, $1,600, $1,750; lots of ten, delivery, 80 days, same price; lots of fifteen to twenty, or more, delivery, 60 days, $1,550, $1,700; four-wheel gasoline cars, Chase and Sanford makes; lots of five, $1,450, Chase; $1,910, Sanford; delivery, 85 days; same prices in lots of ten, fifteen and twenty; lots of twenty or more, $1,400 and $1,875.

Palmer-Myer Motor Co., St. Louis, four-wheel gasoline cars: in lots of five to twenty and above, $1,650.

Krebs Commercial Car Co., Clyde, O., four-wheel gasoline cars in lots from five to twenty and over, deliveries within 40, 50 and 60 days, $1,600.

Dart Mfg. Co., Waterloo, Ia., four-wheel gasoline cars; in lots from five to ten, deliveries, 30 and 45 days, $1,625, $1,515; lots from fifteen to twenty and over, deliveries, 45 days, $1,600, $1,490.

Autocar Co., Ardmore, Pa., any number desired, $1,800 for chassis and $200 for body.

Overland-Washington Motor Co., Washington, D. C., in lots of from five to twenty, deliveries, 60 to 120 days, $950.

Stewart Motor Corporation, Buffalo, N. Y., lots of five, delivery, 30 days, $1,850; lots of ten, delivery, 40 days, $1,775; lots of fifteen, delivery, 45 days, $1,700; lots of twenty and over, delivery, 50 days, $1,625.

C. B. B. Motor Co., Washington, D. C., in lots of five, delivery, 80 days, $1,428, $1,348; lots of ten, $1,428, $1,348.

Wagenhals Motor Co., Detroit, Mich., three-wheel gasoline cars: in any lots up to twenty, $665 and $690, delivery within 30 days; over twenty, same delivery, $625 and $650.

Kentucky Wagon Mfg. Co., Louisville, Ky., four-wheel electric: in lots of five or more, deliveries, 75 to 150 days, $1,690, $1,793, $2,104.

A. Loffler Co., Washington, D. C.: lots of five, delivery, 90 days, $1,850, $1,950; lots of ten, delivery, 90 days, $1,825, $1,925; lots of fifteen, delivery, 100 days, $1,800, $1,900; lots of twenty, delivery, 120 days, $1,775; $1,875; lots of twenty or more, delivery, 150 days, $1,750, $1,850.

Thos. B. Jeffery Co., Kenosha, Wis.: lots of five, delivery, 40 days, $1,410, $1,460; lots of ten, delivery, 45 days, $1,864, $1,414; lots of fifteen, delivery, 50 days, $1,332, $1,382; lots of twenty or more, delivery 60 days, $1,300, $1,350.

FOSTORIA, O., June 21—The stockholders of the recently-incorporated Allen Motor Car Co. have elected E. W. Allen president and W. O. Allen treasurer and general manager. J. E. Wright, formerly with the Columbia Buggy Co., of Hamilton, O., will be active in the concern. Plans have been prepared for a two-story plant, 225 by 65 feet.

Market Changes of the Week

Tin dropped this week to $43.75, a loss of $1.25 per 100 pounds. Lead was quiet, though it fluctuated throughout the week. At the close on Tuesday it was calling at the Metal Exchange at $4.35, a gain of $.02 1-2 per pound. A slightly stronger tone was developed in both electrolytic and Lake coppers. Both coppers dropped $.00 1-8 per pound. Antimony was dull, remaining constant at $.07 1-2 per pound. Beams and channels, Bessemer steel, and open-hearth steel remained unchanged. Cottonseed oil for July passed the 8-cent mark on Tuesday, but did not remain there very long, dropping back again 4 or 5 points during the later session. The advance of $.30 per barrel was hardly to be explained upon any basis in connection with the day's news developments, but the impression seemed to be growing that it was very largely the result of artificial support by the bit refining companies. Both petroleums from the Kansas and Pennsylvania wells remained firm at their old prices, $.88 and $2.50 a barrel, respectively. The rest of the products in the chemical and oil markets also remained unchanged.

Stanolind Saves Money

—

Automobilists Quick To Take Advantage of New Standard Oil Fuel —Gasoline Is Not To Rise in Price

—

CHICAGO, ILL., June 21—The discovery of Motor Spirits, now known familiarly as Stanolind, has saved the automobilists of the ten states served by the Standard Oil Co. of Indiana thousands of dollars since last fall and will save them still more during the present summer through the lessening of the demand for gasoline by owners of stationary engines and tractors. Since Stanolind came on the market there has been no change in the price of gasoline by the Standard Oil Co. of Indiana, and, according to General Manager P. C. Crenshaw, the price will remain the same for some time to come—15 cents f.o.b. Whiting.

The Standard Oil Co. of Indiana is the owner of Motor Spirits and at the present time is manufacturing 100,000 gallons a day at its Whiting plant and 50,000 a day at Wood River. It only recently licensed the Standard Oil Co. of New York and the Standard Oil Co. of Kansas, so that Stanolind soon will be within reach of the majority of the motorists of the United States.

When the new fuel first was put on the market the company had no idea of using it for passenger cars, the idea being that if the owners of stationary engines, tractors and even motor trucks would use Motor Spirits it would relieve the situation in the gasoline field. However, owners of passenger motor cars took kindly to the proposition and soon it was discovered that Motor Spirits makes a most excellent substitute for gasoline. Tests made by the Stromberg Motor Devices Co., of Chicago, as reported in THE AUTOMOBILE at the time, showed that Motor Spirits gave practically the same results as gasoline, while since that time the Standard Oil Co. of Indiana has received many letters from users testifying to the efficiency of Stanolind.

The Gray Motor Co., Detroit, Mich., recently tried out three fuels—gasoline, Motor Spirits and kerosene—using a 6-horsepower 6 by 8-inch stationary engine in one test and a 10-horsepower 5¾ by 5-inch two-cycle marine engine in the other. With the former the results were: Gasoline, 1.13 pints per brake horsepower; Motor Spirits, 1.32 pints per brake horsepower; kerosene, 1.45 pints per brake hosepower. These readings were taken when the engine was adjusted to deliver the exact brake horsepower on the three fuels.

With the larger engine, the results varied from the results obtained on the four-cycle engine, showing a slight loss in power, whereas in the four-cycle the tests showed an increase of 5 per cent. in power.

The Emerson-Brantingham Implement Co., Rockford, Ill., recommends Motor Spirits to owners of Big Four engines and states unqualifiedly that Motor Spirits gives 15 per cent. more power than kerosene and that the economy is greater.

The Otto Gas Engine Works, Philadelphia, has a report from its engineer which shows that its 21-horsepower engine under full load consumes but .753 pint of Motor Spirits per horsepower hour as against .781 of gasoline.

The J. I. Case Threshing Machine Co., which makes tractors in addition to motor cars, testifies that tests made with Motor Spirits in tractor engines of various sizes show that the new fuel gives as good results as gasoline both in horsepower and economy. It also finds that the motors, if anything, will start more readily on Motor Spirits than with any commercial grade of gasoline.

E. D. Kritz, Ford agent at Charles City, Ia., writes that he has been using Motor Spirits in all Ford cars for several weeks and that it is giving satisfaction and that on new cars it works better than basoilne and gives more power. Booth & Probert, Ford agents at West Union, Ia., declare that it gives at least 15 per cent. more power than gasoline, and that after a 300-mile run an examination of the spark plugs failed to disclose any carbon deposit. O. J. C. Kenning, a Buick owner at Grand Rapids, Mich., claims greater mileage and more power on the hills.

Owners of motor trucks are even more commendatory in their remarks regarding Motor Spirits, and among those using it at the present time are Koehler & Hinrichs, St. Paul; the Peter J. Seippel Lumber Co., Dubuque, Ia.; Wyeth Hardware & Mfg. Co., St. Joseph, Mo.; Frank Reter, Clinton, Ia.; Ottumwa Bottling Works, Ottumwa, Ia.; Dennis Bros., Dubuque, Ia.; Brooks Bros., Minnesota Transfer, Minn.; Eggert Transfer Co., Muskegon Heights, Mich.; Canfield Lumber Co., Waterloo, Ia.; Roshek Bros. Co., Dubuque, Ia.; Hesse Building Material Co., St. Joseph, Mo.; Bissell Laundry Co., Chicago; Villaume Box & Lumber Co., Chicago.

—

Big Increase In April Tire Exports

WASHINGTON, D. C. June 24—March automobile exports remained stationary. April figures show only a slight loss. During last April the total value of automobiles and parts exported was $3,469,891, as contrasted with $3,514,210 during the previous month, and with $2,726,500 for April, 1912. The April, 1913, total value of both automobiles and parts was $3,469,891, while the total for the same month last year was $2,726,500. Automobile tires jumped to $305,362 last April, from $194,132 in April, 1912. The tabulation of the number and value of the machines taken by the various countries shows gains in nearly every one, the notable exception being the United Kingdom, which shows a loss of 206 machines, having taken only 373, value $292,167, during last April, as contrasted with 597, value $463,560, in April, 1912.

Automobile motors showed a drop last April, only 954 motors being exported, as against 1,458 in April, 1912. The value increased, however, from $139,335 to $189,783.

A table of the exports and imports follows:

Exports and Imports of Automobiles and Parts for April and the 10 Preceding Months

Automobiles exported to:	April 1912 Quantities	April 1912 Values	April 1913 Quantities	April 1913 Values	Ten months ending April 1911 Quantities	1911 Values	1912 Quantities	1912 Values	1913 Quantities	1913 Values

Illinois for Good Roads

Legislature Has Set Aside $400,000 for State Roads Beginning July 1, 1913 — To Use Convict Labor

SPRINGFIELD, ILL., June 21—The Illinois legislature adjourned last night and one of its last acts was to enact into a law the good roads measure. It didn't pass in its original form as prepared by Representative Tice but the bill contains many features agreeable to the motorists and is regarded as a step in the right direction.

The legislature remedied the oversight which prevented the use of registration fees for road maintenance and has set aside $400,000 out of the fund for the use of the highway commission for the year beginning July 1, 1913, in the construction of state-aid roads. A similar sum was given for the previous year. Appropriations from the general fund of $300,000 each for the years 1913 and 1914 for the state highway commission to build and maintain state-aid roads were made. Sheridan road, running north to Milwaukee, was placed under control of the Lincoln park commissioners to the Wisconsin state line.

Illinois also has come out for the employment of convict labor on roads, one of Governor Dunne's administration measures. The new law provides that upon the request of highway commissioners in any township or county board the commissioners of the Joliet or Chester penitentiary or the board of managers of the Pontiac reformatory may detail prisoners for the employment on the public roads or in the preparation of road-building material.

The new road law provides for the reorganization of the road-building system of the state under the direction of three members to be appointed by the governor, the salaries to be $3,500 each per year for a 6-year term.

Keystone Governor Approves Jones Bill

HARRISBURG, PA., June 23—Governor John K. Tener has approved the Jones bill, appropriating $1,000,000 to pay the 50 per cent. bonus on cash tax in second class townships. The bill provides for the deficiency which has arisen because of insufficient appropriations by the 1911 legislature.

INDIANAPOLIS, IND., June 25—*Special Telegram*—The Severin Taxicab Co. is being organized here with $100,000 capital. It will operate twenty-five taxicabs and establish a garage with capacity for 100 cars.

Brazil Wants Automobile Factories

NEW ORLEANS, LA., June 20—Now that Brazil has made arrangement for several rubber factories, the next effort is to be directed toward getting automobile factories. A plan already is being considered by the industrial department of the government, which will provide for a subsidy sufficient to encourage the location of a branch plant of an established concern manufacturing a standard car. As the government came to the United States for its rubber manufacturers it is considered probable that preference will be shown Americans in the contemplated enterprise.

A. O. Smith Passes Away

MILWAUKEE, WIS., June 23—The automobile and motor truck industry lost a conspicuous figure when A. O. Smith, president and founder of the A. O. Smith company, passed away on June 20. Mr. Smith was 54 years old and had been in poor health for several months. L. Raymond Smith, who has been his father's right-hand man for several years, will succeed him as head of the company and general manager of its business.

Stearns Co. To Expand—Raises Capital

CLEVELAND, O., June 21—Appplication has been made by the F. B. Stearns Co., for an increase of $200,000 in its capital stock. Some time ago several parties heavily interested in the company acquired control of nearly 400 feet of Euclid avenue frontage adjoining the Stearns factory on the west and extending back to the Belt Line R. R. tracks, which circle the city. It is now advisable for the stockholders of the company to acquire this additional land to provide for extensions of the business.

An agreement has accordingly been reached whereby the company acquires control of this land by an exchange of the Realty company's securities for stock of the Stearns concern under certain conditions, $47,000 of this stock being issued for this purpose and the balance retained in the treasury. The Stearns company has increased its stock to effect this exchange and has in contemplation considerable new construction.

United Motor Chicago Co. Bankrupt

CHICAGO, ILL., June 25—*Special Telegram*—A voluntary petition in bankruptcy has been filed by the United Motor Chicago Co., formerly the Maxwell-Briscoe Chicago Co., representing the United Motors Co., before the reorganization. The liabilities were placed at $108,140.54 and the assets at $27,173.

Studebaker Strike Is Over

DETROIT, MICH., June 25—*Special Telegram*—While the strike at the Studebaker plants here was not officially called off by its instigators until last night, the big corporation has been running with a full force all week and is turning out as many cars as usual. Although the concern did not stop building automobiles during the strike period it was, of course, not running to full capacity at that time. At no time, however, were more than 2,800 men out which is only about one-quarter of the total working force so that manufacturing was not seriously crippled at all.

American Voiturette a New Small Car

DETROIT, MICH., June 24—The second of the small cars to make its debut in Detroit is one of the models to be turned out in quantities by the American Voiturette Co., a $500,000 concern which has for its backers C. B. Shaffer, President, and W. G. Houck, director of sales and second vice-president of the Keeton Motor Co., and others. The company plans to make three models, a tandem, for carrying two persons; a roadster for two side by side, and a four-passenger type. These are to sell for $495, $505 and $510, respectively.

Sixty Men Strike at Adams Plant

FINDLAY, O., June 20.—Sixty men in the machine shop of Adams Bros. motor truck works went out to-day because of the intolerance, as they allege, of two men, foreman and superintendent, imported from Detroit. The plant is turning out five trucks a week, and the new men say the output should be twelve. No violence has resulted.

Cars Not Allowed in Yellowstone

WASHINGTON, D. C., June 22—Some time ago announcement was made that Secretary of the Interior Lane had thrown open Yellowstone National Park to motor cars. Officials of the department say that is manifestly incorrect and they are at a loss to account for the wide publicity given the matter. As a matter of fact, motor cars are not permitted in the park except on that part of the road from Bozeman, Mont., to Yellowstone, Mont. The department is endeavoring to get an appropriation of $2,000,000 from Congress in order to widen the roads leading into the park.

Bretz Outing Great Success

NEW YORK CITY, June 25—The J. S. Bretz outing, which was held yesterday on Staten Island, was one continuous round of pleasure for the magazine, newspaper and automobile men who were the guests. Cricket, baseball, field sports and tennis tournaments made the time slip merrily away.

The Carriage and Wagon Industry in 1909

WASHINGTON, D. C., June 21—Statistics in detail of the carriage and wagon industry of the United States for 1909 are presented in a bulletin soon to be issued by Director Durand of the Bureau of the Census, Department of Commerce. The 5,492 establishments in both branches of the carriage and wagon industry of the United States gave employment in 1909 to an average of 82,844 persons, of whom 69,928 were wage earners, and paid $45,555,126 in salaries and wages. The carriage and wagon industry has existed in this country since early Colonial times, and its growth up to the census of 1904 about kept pace with the increase of population. The advent of the automobile, and later of the motor truck, has had a decidedly retarding influence on the industry. Many establishments in the early days manufacturing carriages have turned to the manufacture of automobiles.

The following table gives the figures in detail:

	Carriages and Wagons and Materials				
	Number or amount			Per cent. of increase*	
	1909	1904	1899	1899-1909	1904-1909
Number of establishments	5,492	5,588	6,792	—19.1	— 1.7
Persons engaged in the industry	82,944	90,751	(a)	....	— 8.6
Wage earners (average number)	69,928	77,882	73,812	— 5.3	—10.2
Capital	$175,473,728	$152,344,657	$128,961,660	36.1	15.2
Wages	37,594,919	38,362,679	33,565,313	12.0	— 2.0
Value of products	159,892,547	155,868,849	138,261,763	15.6	2.6

*A minus sign (—) denotes decrease. Where percentages are omitted, comparable figures cannot be given. (a) Comparable figures not available.

Franklin Breaks Fuel Economy Record

Covers 86.6 Miles on 1 Gallon of Gasoline—Record Was 46.1 Miles Held by 1913 Franklin

NEW YORK CITY, June 21—Yesterday a specially-constructed Franklin car broke the record for the distance traveled by an automobile on a gallon of gasoline, going a distance of 86.6 miles over Long Island roads.

The former record for an automobile was 46.1 miles and was held by a 1910 Franklin car weighing, with passengers, 2,948 pounds. The motor was an 18-horsepower type and the car carried a touring body. The car which made the present record is equipped with a sheet aluminum body in the form of a two-seated roadster with torpedo lines. The weight of the empty car in running condition is 1,695 pounds. Its total weight with the driver and passenger is 1,995. The former record was made in competition in July, 1909, while the present record was made as a test under the supervision of the Automobile Club of America.

The driver was S. G. Averill, the owner, who was accompanied by Herbert Chase, laboratory engineer of the Automobile Club of America, who acted as official observer. Mr. Averill was also the driver of the car making the record in 1909. The car he drove at that time was one of the first of the 1910 Franklins. In this competition Averill exceeded the mileage of his nearest opponent by 20.4.

Everything was done to reduce the coasting resistance of the car used in this trial for the record. Ball bearings were placed on the rear axle, a Newcomb carbureter fitted, the spring cut down so that there were but four blades in each half of the elliptic front and rear springs, the drive was taken through the springs and through one rear wheel, the other running free. One set of brakes, controlled by the hand, was used, 34 by 3.5-inch plain clincher tires pumped to a pressure of 35 pounds were fited. The brake drums were even perforated to bring the weight to its absolute minimum. Wind resistance was cut down by using the stream-line torpedo body, which carried a tapering cowl to cut the resistance.

The gasoline used was 63 Beaumé test carried in a measured copper receptacle on the dash before the observer's seat. This was fed by gravity to the Newcomb carbureter which was standard except that the easy-starting, air shut-off valve was omitted. The odometer used was a Casgrain.

The course followed was on the Queens boulevard. The car traveled from the Williamsburg bridge out Queens boulevard to Hillside avenue, Jamaica, swinging left to the Jericho turnpike which was followed to the hamlet of Jericho where a turn was made across the island and then back over the same roads to the starting point. On the return to the starting point it was found that a little better than 60 miles had been covered and that some gasoline still remained. The remaining 20 miles was covered by a trip out Jackson avenue, and back and then another out the same route and nearly back to the starting point, so that the car went up practically every grade that it went down, although at times it seemed as if the car was fairly coasting up grade, so easily did it run.

Country passed through on the Franklin test was fairly level with an occasional 2 or 3 per cent grade. The test lasted six hours, which makes an average speed over the entire distance of 14.5 miles per hour on regular touring speed. The driver would open his throttle until he had attained a speed of close to 20 miles an hour and then would stop the motor and coast.

It has always been a fascination to determine what mileage can be secured from a gallon of gasoline. A motorcycle has traveled 190 miles on 1 gallon and 10 ounces. This was done by S. A. Baker, September 13, 1907. The average accomplishments, however, of stock models with regular bodies fall far below these record tests. The average gasoline automobile travels from 15 to 20 miles on a gallon, although some touring cars go as low as 4 miles to the gallon and others as much as 28. The average steam automobile goes 10 miles to the gallon. The average aeroplane 10 miles to the gallon, but with its fuel mixed with lubricating oil. The average motorboat of corresponding horsepower to an automobile goes about 12 miles to the gallon, while a single-cylinder motorcycle will average better than 75. The strength of gasoline may be fully appreciated from the fact that it has been stated that could the entire energy contained in 1 pound be utilized it would lift a 1-pound weight 15,941,220 feet.

Elgin Entry Blanks Now Ready

CHICAGO, ILL., June 23—Entry blanks for the fourth annual Elgin road races, scheduled for August 29-30, were issued today by the Chicago Automobile Club, providing for two races only, the 300 and under class for the Cobe cup the first day and the 450 and under for the Elgin national trophy the second day. Hardly had the blanks been out before the first entries were made. E. C. Patterson, general manager of *Collier's Weekly*, nominating two Mercedes six-cylinders for the second day's race. One of these will be driven by Victor Hemery and the other by Theodore Pilette, the two foreigners.

Many Entries for Columbus Races

COLUMBUS, O., June 21—Entries for the 200-mile sweepstakes automobile race to be held at the Columbus Driving Park, July 4, under the auspices of the Columbus Automobile Club, are coming in fast. The contest committee of the Columbus Automobile Club has received word of the entry of De Palma in a Mercer, Spencer Wishart also in a Mercer, Fritsch in a Cino, Rickenbacher in a Mason, either Ralph Mulford or Houpt in a Mason, Whalen in a Schacht and others. In order to furnish sufficient seating capacity the committee has arranged for 8,000 circus seats to be placed to the south of the grandstand which will increase the seating capacity to about 20,000.

Ohio Wins Special Match Race

CINCINNATI, O., June 21—A special match race between Johnny Raimey in an Ohio "99" and Horace Heisey in a Buick "40" supplied the feature of an otherwise tame program in the annual hill climb of the Cincinnati Automobile Dealers' Association today. Heisey won by negotiating the course in 0:29 3/5 on his first attempt. Both dare-devils got two trials. On his second spin up the hill Heisey was slow, 0:33 3/5 being his time. Raimey's best was 0:29 4/5. Both are local drivers. The course is 100 yards less than a half mile.

The entry list was a small one. In some races only one car went up the hill. No outside drivers of note could be induced to come here for the meet. Over 10,000 people thronged the course, which was in splendid condition. The weather was very hot. The only accident during the day occurred in the second race, when H. D. Shane in a Metz swerved in going around a curve and bumped into a tree.

L. I. A. C. To Hold Run for Jordan Trophy

NEW YORK CITY, June 24.—The Long Island Automobile Club will hold a 3-day run to the Berkshires for the Jordan trophy, Friday, July 4, to Monday, July 7. There will be 2 days of actual running. Penalties will be imposed for taking on water, gasoline or oil between the controls, Poughkeepsie, Pittsfield and Waterbury. The club will also hold a secret time run to Babylon, L. I., July 4, for the Major cup.

COLUMBUS, O., June 21—After parleying around for several weeks, the Ohio State Journal Reliability contest which had been postponed several times, was officially called off by the contest committee of the Columbus Automobile Club. This was done after it became too hot for the race to be run with comfort.

Franklin car which broke fuel economy record

Zuccarelli Killed in Practice Run

Driving at 100 Miles Per Hour on Grand Prix Course, Hits Wagon—Mechanician Dies

PARIS, FRANCE, June 19—*Special Cable*—Paul Zuccarelli, one of the Peugeot drivers who recently returned from the 500-mile race at Indianapolis, was killed outright and his mechanician, Fanelli, was mortally wounded today when the racing car in which they were practicing for the French Grand Prix collided with a farmer's wagon, which suddenly emerged from a side road between Nonancourt and Evreux.

Zuccarelli's car was speeding at nearly 100 miles an hour when the accident occurred, the automobile driving straight through the cart but overturning on top of the occupants.

PARIS, FRANCE, June 13—Jules Goux, winner of the Indianapolis 500-mile race, and his team-mate Paul Zuccarelli, landed at Havre this week, where they were met by Georges Boillot and the European representative of THE AUTOMOBILE. Stepping off the gangway of La France, Goux saluted Boillot in military style and said "Boss, you sent me to America to win the first prize; I've won it."

In conversation with THE AUTOMOBILE representative, Goux expressed himself as delighted with the treatment he had received at Indianapolis. "There was absolutely no favoritism, the Peugeot victory was well received, and the officials gave us every assistance. Carl Fischer and C. W. Sedwick were particularly attentive, and A. C. Newby, of the National Motor Car Company, placed his factory at our disposition. I doubt if it would be possible to find any maker in Europe who would do as much. It is almost certain that I shall run at Savannah next fall, and I shall be disappointed if I am not one of the starters in next year's race at Indianapolis."

Jules Goux declared he had never seen such magnificent organization in connection with an automobile race as that at Indianapolis. "There is nothing in the world to approach it. I consider the management perfect in every detail. The track is not fast, compared with Brooklands, for instance, and had it not been for the impossibility of taking the turns fast, consistent with the life of tires, I should have shown a much higher average. I consider that I had an easy win, and from the moment the start was given I felt confident that the race was in my hands.

"I was handicapped by being geared too high. My ratio was 2 to 1, which was the ratio adopted for road work with a cylinder bore of 110 mm. We had cut the bore down to 108 mm. and not changed the ratio. I found that in order to make my right rear tire last a reasonable length of time I could start my turns at 85 miles an hour, but had to finish them at not more than 73 miles. After being cut out on the bends the straightaways were not long enough to get the motor up to its highest number of revolutions. The fastest I could get on the straightaways, without considering the life of tires, was 99 miles an hour; with a suitable gear ratio I could have done 112 miles an hour. In consequence of this the motor was always running at a lower number of revolutions than that for which it was designed. At first I did my laps in 1.40, and could have kept to 1.45 throughout the race if it had been necessary. When I had got a couple of laps lead on my nearest competitor I considered there was nothing to be gained by going faster than 1.50 per lap. I broke last year's records up to 200 miles and could have broken them for the entire distance if there had been anybody really dangerous behind me. I hope that in next year's race the cylinder capacity will be reduced still more. With smaller motors and lighter cars it will be possible to get the same average speed as this year. I hope to prove this with our present season's Grand Prix racers."

National Tour Promises Success

MINNEAPOLIS, MINN., June 23—With several entries already filed for the A. A. A. national reliability tour, Twin Cities-to-Glacier Park, July 11-19, others promised, and more than 100 interested applicants for information from all over the United States the outlook for a big field is said by Dr. C. E. Dutton, chairman of the tour, to be excellent. A meeting was held Tuesday noon, this week, at the Commercial Club between the Civic & Commerce Association tour committee, the general entries committee of the Automobile Club of Minneapolis, and the Minneapolis Automobile Trade Association at which the project was given a big push. The Mitchell Moose pathfinder, which has just completed laying the route to Glacier Park station with Frank X. Zirbs as driver and C. A. Stedman as pathfinder, will return at once to get ready to become pilot in the tour. David Beecroft of the contest board has been appointed referee.

The entries to date are:

Louis W. Hill, St. Paul, Packard 30, 1909 model, four cylinder runabout, 5 by 5½ inches, two passenger, Anderson trophy.

C. H. Metz and H. W. Metz, Waltham, Mass., G. H. Voter, Boston, Metz ears, 1913 model, A. A. A. trophy, Glidden trophy.

H. F. Legg, Minneapolis, Stutz, 1913 model, four cylinder runabout, 4¾ by 5½ inches, two passenger, Anderson trophy, and with Premier and Reo to be entered, the Anderson trophy.

H. W. Automobile Company, three Krit cars, 1913 model, four cylinder runabout, 3¾ by 4 inches, Glidden and Anderson trophies.

Dr. Clinton A. Smith, Devils Lake, N. D., KisselKar, 60, 1912 model, four-cylinder runabout, 4.5 by 4.75 inches, Anderson trophy.

Fawkes' Automobile, 60, Minneapolis, Premier, 1913 model, six-cylinder, 4.25 by 5.5 inches, Glidden, A. A. A. trophies (team with Stutz and Reo car to be entered).

Indiana Makers Tour Ready to Start

INDIANAPOLIS, IND., June 23—Final arrangements for the Indiana-Pacific tour, under the auspices of the Indiana Automobile Manufacturers' Association and to start from here July 1, were made at a meeting held in this city last Tuesday night. The tour will start at 2 p. m. from University Park and there will be a large escort to the city limits. A letter has been sent to the mayor of each city through which the tourists will pass by Mayor Shank. Tourists are to wear khaki and puttees. Equipment will include an extra oil tank, a Compac sleeping tent, a suit case rack and a kitchen and lunch hamper. There are now twenty-two formal entries and may be more before the start.

Franklin Wins in Watson Cup Run

SYRACUSE, N. Y., June 21—Edward F. Sparks, driving a Franklin car, won the secret time sociability run of the Automobile Club of Syracuse. The official time was 2:57:30 and Mr. Sparks was just 12 seconds distant from it, covering the route in 2:57:18. This gives him possession of the Watson cup for a year, and the plan is to have Mr. Sparks and the three previous winners of the cup hold a contest next year, the winner to retain the trophy permanently. Mr. Sparks also won 5 gallons of Monogram oil by coming nearest the secret time. The other winners, taking various automobile merchandise, in their order and cars, follow: Simon Rosenblood, Haynes; A. J. Conine, Buick; Louis Leonard, Krit; G. F. E. Meistering, Abbott-Detroit; C. A. Lawton, Franklin; Edward C. Heise, Cadillac. Miss Edith Gere won the women's prize of a camera outfit, also the Ford prize of a thermos bottle and case.

Wisconsin Tour Pathfinder Starts

MILWAUKEE, WIS., June 23—The Mitchell 1914 6-60 pathfinder for the fourth annual Wisconsin reliability tour, under auspices of the W. S. A. A. left Milwaukee Saturday, June 21, to blaze the 800-mile trail which will be followed by the contestants in the run from August 18 to 22, inclusive. M. C. Moore, who will again do the pathfinding, has made some changes in the route, which at present is as follows: First day, Milwaukee to Appleton, 151.7 miles. Second day, Appleton to Marshfield, 191.5 miles. Third day, Marshfield to LaCrosse, 166.4 miles. Fourth day, LaCrosse to Madison, 150.2 miles. Fifth day, Madison to Milwaukee, 151.7 miles.

Keeton Challenges Indianapolis Winner

DETROIT, MICH., June 23—Wm. G. Houck, director of sales and second vice-president of the Keeton Motor Co., has posted a check for $10,000 with the *New York World* as a challenge for Jules Goux, winner of the 500-mile race at Indianapolis on May 30, to race Bob Burman in the Keeton car, which also competed in that race. Goux is now in France preparing for the Grand Prix on July 15, and it is doubtful if he will accept the challenge.

Gasoline Price Is Not To Rise

THAT "necessity is the mother of invention" has been well demonstrated in the automobile fuel field. On January 1 of this year the weekly supply of gasoline was approximately meeting the demands, but manufacturers were uneasy, they feared that demand might exceed supply and that the consequent increase in prices would result. At that time one of the large gasoline producing companies was working on a new fuel, motor spirits, now known as Stanolind, which has since its entering the market a few months ago practically eased the fuel market so that last week it was learned that there is no danger of any immediate rise in the price of gasoline. This is welcome news, particularly when it is remembered how there was a 50 per cent. increase a year ago and how at present the price in several European countries is going up steadily.

Motor spirit must be given much credit for the present stationary prices, because by means of it the amount of fuel from a gallon of crude has been practically doubled, the refinery getting the regular quantity of gasoline and an equal quantity of Motor Spirit from a gallon of crude, which has more than doubled the available supply.

While motor spirit was originally intended for farm tractor and stationary engine work and perhaps motor trucks, it has really been taken up quite extensively by the light car owners.

Quality Is Wanted in Tires

KEEPING step among the various departments that go to make up the motor car has been one of the factors largely instrumental in the phenomenal growth of the industry. Had the body building department lagged behind that of chassis design slower progress would have been made; so, too, had tire makers fallen in arrears the general progress would have been impeded. Tire makers have been particularly active, and although at one time the price of crude rubber rose so as to give rise to uneasiness, the prices are today back into normal channels; and so great are the improvements in rubber culture that there is little, if any, danger of any shortage in spite of the increasing number of motor cars and motor trucks being used.

Tire manufacturers have a difficult rôle to play because of the guarantee feature, and further because they have suffered badly due to poor roads as compared with other countries. A few years ago the tire cost per mile was much in the public eye, but with the increased price of fuel and other added costs to motoring the tire factor has moved slightly out of the limelight. The recent cuts in prices have had something to do with this, but it is questionable if price cutting is going to produce the looked-for results. Price cutting will be welcomed by the entire motor fraternity if quality is maintained, but it is a point for argument if improving the quality of the tire and retaining the price might not be a more desirable course.

If there is any part of the car in which maximum quality is looked for it is in the tire field. The continual demand for tire fillers and other protective measures against punctures and blowouts proves that the tire nightmare is still with many motorists; and while demountable rims, power air pumps and other conveniences have done their part, there are still looked-for improvements. If a better grade of fabric can be used in tires it will be welcomed; and if there are better methods of vulcanization, or improvements in any of the processes of tire building, the car owner would welcome everything possible by way of adopting them.

The use of larger tires must be looked upon as a step in the right direction and there are still today cars that are undertired. With several car builders the car weight has increased during the last two years. Batteries for motor starters have been added, motor starters have increased the weight. Demountable rims have added a few pounds; and the full dinner pail equipment has added weight. In some cases the car builder has been fitting the same size of tire and when vehicles have been weighed both tire maker and car maker have acknowledged that the tires were not adequate to the load. It is poor policy for both car maker and tire maker to send out an undertired machine. It is sure to give trouble and particularly in these days of road improvements, when harder road surfaces are coming into vogue and when average speeds along the highways are on the increase. Car owners are already finding that the hard, flinty roads work rapidly on tires by way of making small surface cracks and cuts, which cuts must receive early attention or otherwise the water and dirt entering these openings will soon ruin the fabric.

American vs. European Salesmen Abroad

By John L. Poole, Resident European Export Manager for the Hupp Motor Car Co.

ABOUT the first thing a manager of the American company thinks he must have when he contemplates going abroad into the export trade is a salesman "from abroad," one who can speak at least two or three different languages besides English.

In a number of such cases men were brought over and after 2 or 3 months at the factory returned to Europe to represent an American motor car. In each and every case of this kind, such salesmen have proven a complete failure.

Their ideas of conducting a foreign campaign are by the usual old time European methods; and with a line of American motor cars, success is out of the question. Up-to-date ideas are required over here for American automobiles just as much as at home. Good, wide-awake salesmen are required—men who will work and not sit around cafés and smoke cigarettes all day; men who have confidence in themselves; men with nerve and sand who will not permit any European to "run in a bluff" on them; men who are loyal to their employers, their goods and their country. Such men from Europe for an American motor car company are not be found at any price.

It is not absolutely necessary for the bright American to speak foreign languages, but it would be of great assistance to him to know French and German.

If I wanted a dozen salesmen today I would not engage a single European to represent an American company—not but that they may be all that is necessary for an European maker, they are not suitable to do business and represent an American manufacturer. The American worker is the man—even if he can speak only English. He can do business all around the best men in all Europe for American goods. He has his own way—and it's the good, American way, too. That in itself will gain him an opening and he is always ready to take advantage of such opportunity. He thinks and acts quicker; he has confidence in his ability, and above all, he is a far better judge of his customer.

Furthermore, it is absolutely necessary to have men over here who are able to act at all times, independently, and not be compelled to cable for instructions every time some important matter must be decided quickly. You can not find men in Europe who are capable of acting in this manner very easily. This is due to their business training. They are brought up to be dependent—not independent like our Americans. There is always over here an Over-Director, or Manager, and to him the European salesman must first obtain his consent in everything before he can act, and the Over-Director must obtain the Master's consent and so it goes on and on.

In other words, I claim that the salesman over here is far behind the times—as far as his use to an American firm is concerned. The American salesman on his first trip must be careful. He soon "catches on," however.

Remember—you can't rush things over here. There are no "one-night stands." It is usually a week and sometimes 2 before you find your man. Remember—Rome was not built in a day, and for that matter, no export business either. Don't get discouraged too quickly; study the conditions of each country carefully; get to know your customer on a friendly basis, and above all, do not over-estimate your business. Remember, that nearly all of these men have friends in the United States of America who can give a line on what you are doing at home. Be careful and make no mis-statements. Whatever you promise, fulfill to the very letter. Above all, do no knocking, especially against your American competitors. A case of this kind took place not long ago. A new man from the United States called on a firm in Vienna and on this firm asking the young man if he knew the Hupmobile car and your correspondent, he had little if any good to say, for either the car or its representative. It is not necessary to say who made the deal.

I must add I have never seen the young man, but I know his firm quite well, and I am also glad to say that cases of this kind are rare over here.

My advice I know is old and well known to the good American salesman, but some of them forget when they cross the Pond and get so far away from home and all the things and people to which they are accustomed.

Personally, I am glad to see the boys from home no matter whom they represent. There is room for us all, and I trust that the American makers will send their own countrymen over here when they do decide to take up the export business.

Co-operation of Truck Makers and Buyers

By J. M. Lansden, Second Vice-President of the General Motors Truck Co.

IT is to be regretted that many motor trucks now in operation have been sold to meet the buyer's personal ideas—not his needs. But the shrewd investor in motor vehicles today is beginning to appreciate more and more the wisdom of working with a competent motor truck man to ascertain the type and size of equipment to best meet his requirements.

Foreign buyers believe in this method of purchase to such an extent that certain companies in France and England, known as "transportation engineers" make a business of studying delivery and haulage problems, undertaking to buy and install for clients such equipment as their experience and training teaches them is most efficient for the work in question.

In the past it has been customary for the buyer to tell the truck manufacturer or representative that he wanted a gasoline truck or an electric of such and such a size. If, after the vehicle or vehicles had been placed in operation, the installation did not show sufficient earning on the investment, the buyer was prone to say that motor trucks were unsuccessful in his business or that horses were cheaper. Rarely did he express the belief that the trucks purchased were not properly fitted to his service.

The results of this sort of buying have been in many cases so unsatisfactory that both large institutions and small ones are beginning to take the position that it pays to entertain the recommendations of a reliable company who are not prejudiced for commercial reasons in favor of one type or size of vehicle. At the direct factory branches of many of the truck companies men are stationed who are equipped to advise with prospective installers and co-operate with them in the selection of equipment which represents the utmost in efficiency and economy for their particular needs. And when we stop to consider, this policy is strictly in line with the methods employed by men who are selling many different kinds of commercial units.

The Engineering Digest

Change-Speed Transmission By Compressed Air, with Direct Drive, Likely to Make Devotees of Hydraulic Devices Sit Up and Think—Sigma Again on the Tapis

Fig. 1—The locomotive with automobile motor and variable-speed transmission on the Hautier system, which has been in use in yards of Schneider works in France for one-half year and found very efficient — Radiator and condenser on top of the engine cab — All wheels driven

COMPRESSED-AIR Transmission on the Hautier System.—Since the advent of motor-starters, with the small electric or compressed-air auxiliary power plant which they necessitate, the idea of operating the change-gear mechanism by the same plant, perhaps automatically, has advanced beyond the speculative stage, and it now engages the attention of the research engineers who have in mind the improvements to be incorporated in models for 1915 or 1916. At the same time the problem of producing unabusable gasoline motor trucks, and these, by the way, suitable for being operated with kerosene, benzol or other cheap fuels as well, if needs be, and also special trucks for slow work—whose operation and maintenance must be particularly inexpensive—suggests hydraulic clutches and drives or else electric or compressed-air devices from which it may be possible to bypass a little power when it is wanted for some of the incidental necessities of motor traffic. These two tendencies work hand in hand and are already setting fruit in different inventions, some of them coming from quarters not directly identified with automobile manufacture and perhaps therefore more likely to view the requirements of the immediate future in a free-minded perspective. As examples may be mentioned the Breslauer electric speed-change mechanism of reduced weight (as compared with previous types of gas-electric equipment serving the same purpose) which was recently described in *The Electrician* and the Wells hydraulic clutch described in *Power.*

A remarkable system for power transmission which comes within this class has recently been tried in France in connection with an internal-combustion locomotive built for use in the yards of the Schneider works at Creusot where it has been in service since December 1912. The fuel used for the motor is crude naphtaline for normal operation and benzol or gasoline for starting. The motor develops up to 72 horsepowers, at 1,000 revolutions per minute, and is of the automobile type with thermo-siphon cooling adjusted to allow the water to steam freely, but the radiator which is arched crosswise over the roof of the locomotive returns the condensed steam to the water system, these dispositions assisting in operating the motor so hot that the naphtaline can be melted from the waste heat even if the motor is running very slowly. The locomotive weighs 19 tons and the tractive pull required of it reaches a maximum of 3,500 kilograms, at starts on grades, while the normal pull is about 750 kilograms. The maximum speed is 23 kilometers per hour. It passes daily through a tunnel separating the two portions of the Schneider works which are located respectively at Le Havre and at Harfleur, and it was the necessity for this subterranean passage which suggested a smokeless power system.

The Hautier transmission system admits of varying the torque and speed of the driving wheel axle progressively and continuously and also stores in a special tank, S in Fig. 2, the compressed air by means of which the motor is started. The illustration shows the arrangement of this transmission diagramatically, and the mode of operation is made plain by including the control levers in the chart.

To the shaft O which is turned directly by the prime motor there is keyed the spur-wheel B which meshes with pinions C, these being mounted upon stubshafts extending from the cross-beam E fixed upon the transmission shaft F. A drum H containing these parts is journaled upon both O and F and provided with an internal gear ring (not shown) meshing with pinions C, and a spur-crown I formed externally upon the hub of drum H meshes with pinion I′ which is mounted upon the shaft of a four-cylinder single-acting air-compressor K.

A socalled starting lever D admits of holding the suction valves of this compressor open, when the lever is in the "stop" position, thereby causing the compressor to run idle.

Oppositely to the compressor, with reference to shaft F, there is arranged a four-cylinder compressed-air motor whose shaft carries pinion P in mesh with spur-crown P′ which is keyed on shaft F. The camshaft of the air-motor can be displaced longitudinally by means of lever A, so as to vary the admission and expansion of air in its cylinders.

The discharge ports of the compressor are connected with the admission ports of the air-motor and also with the tank S, the pressure to be reached in the latter being limited by a check-valve T.

When the vehicle is at rest and the prime motor running, the levers D and A are in the positions indicated in Fig. 2. Spur-wheel B tends to rotate pinions C and therefore, by the action of the planetary gear, also the shaft F which at the other end controls the driving wheels of the vehicle, but the rotation cannot be materialized unless the pinions C are resisted by the internal gear teeth in drum H, and, under the condition assumed, this drum presents practically no resistance to rotation, as the valves of the air-compressor are held open; and therefore no force is applied to rotate shaft F and move the locomotive. In order to make the vehicle start it is sufficient to move the lever D to the position "On." The compressor valves are then rendered operative and the work of the compressor creates a resistance to the rotation of drum H while sending at the same time air to motor N. The motor-torque of pinion B is decomposed into two portions, through the intermediation of the planetary gear: The portion acting upon the beam E tends by direct action upon shaft F to advance the vehicle, and the portion taking effect on drum H works according to the adjustment of the compressor.

In proportion as the air pressure is increased—by admitting more air from the compressor to the air-motor—the reaction from the compressor work is transmitted back through the planetary gear so as to increase the torque acting through shaft F, while reducing its speed, and at the same time the air-motor develops a certain torque which is transmitted through pinions P and P′, also to shaft F, reinforcing the turning moment directly applied to it. Under the influence of these forces the locomotive starts very gradually, tautening the trailer couplings entirely without jerks.

As soon as the vehicle is barely moving, the operator pulls lever A so as to reduce the period for admission of air to the air-motor, thereby increasing the resistance against the functioning of the compressor and reducing its speed. And, through the action of the differential gear (the planetary gear in connection with beam E constituting a differential) this slowing-up of the compressor produces at once a more rapid rotation of shaft F and consequently an acceleration of the vehicle.

On a grade the operator determines readily the position of lever G which is most suitable for utilizing the whole power of the prime motor at any throttle adjustment. On level ground he pushes lever A completely to the left, at which adjustment air-motor N takes no more air and forces the compressor to stop working; this stops drum H from rotating and the transmission between prime motor and driving-shaft is now "direct", the speed reduction being determined only by the ratio of the intervening gears, B, C and H. The power continues, however, to be applied through the interposed air-cushion in the compressor cylinders.

The quadrant for lever A has four notches of which No. 1 corresponds to an air admission of 90 per cent to the air-motor (for starting the vehicle), No. 2 to 30 per cent., No. 3 to 8 per cent. and No. 4 to complete closure (for direct drive).

To stop the vehicle with the motor running it is sufficient to set the throttle on "slow" and lever D on "neutral", while for a prolonged stop of the locomotive the motor is brought to rest by operating lever G. Finally, in order to start the motor again, lever G is pushed back to a position causing the air-motor to be actuated somewhat, and the petcock V is opened, which admits air from tank S to the combustion chambers of the prime motor. The air-motor can be made to function as a compressor for braking purposes, acting like reverse steam in a steam locomotive, by placing lever A in a special notch. The braking effect is in that case graduated by means of a relief cock. The locomotive is, however, also equipped with an air-brake operated with air from tank S.

The reverse is obtained by having at the end of shaft F a bevel pinion in mesh with two idler pinions mounted upon a transverse shaft. A coupling sleeve controlled by lever D' admits of the clutching one or the other of these pinions to this shaft, thereby determining the direction of its rotation. The transverse shaft, in the actual construction of this locomotive, drives another transverse shaft through the gearwheel R, and from this the vehicle wheels are driven by a walking-beam connection. The front and rear wheels are coupled together, so as to get the benefit of the entire weight of the structure for adhesion and traction.

The efficiency of the whole vehicle mechanism, from prime motor to wheel rings, was found at public tests to range from 67 to 93 per cent, according to load, trailer load (maximum 125 tons) and road gradient.

The report of the testing engineers dwells upon the possible applications of the Hautier transmission system to railless transportation and street cars, for which purposes they hold that it offers unusual advantages.—From *Le Génie Civil,* May 31.

—

THE Co-efficient Sigma.—The following letter has been received and explains itself:

DEAR SIR:—In your issue of June 5, in noticing my article on "The Coefficient Sigma," which recently appeared in *Internal Combustion Engineering,* you remark that the formula I propose does not disclose in what manner the volumetric efficiency of the motor and the qualities of the carburetor have been set aside and eliminated from consideration.

If you will refer to the article in question, you will note from the equation 1 that the total volume of the cylinders is taken into consideration. Later on, this equation (No. 4) is modified to give the total displacement per ton mile, this being the standard of comparison for the car's performance. In other words, it is assumed that the motor is capable of drawing its full capacity of gas into the cylinders at every revolution, which, of course, is never achieved in practice. That is to say, the volumetric efficiency of the motor is assumed to be one hundred per cent. If the volumetric efficiency of the motor fall off very much, it is obvious that the horsepower will diminish and the use of a lower gear will be necessary. Consequently, the g which appears in the formula takes care of this indirectly.

Again with regard to the carburetor, I have stated that 15 pounds of air per pound of gasoline are required. If the carburetor is imperfectly adjusted to get too rich a mixture, the number of miles per gallon will diminish because more gasoline is consumed. Consequently, the more perfect the carburetion and the greater the number of miles per gallon, the higher will be the value of sigma.

I hope that I have made this matter clear.

H. KERR THOMAS.

June 13, 1913.

The explanation given by Mr. Thomas in the above letter represents exactly the understanding of the matter which the reviewer had arrived at and had aimed to express in his note. It may then be assumed now that the purpose of co-efficient sigma

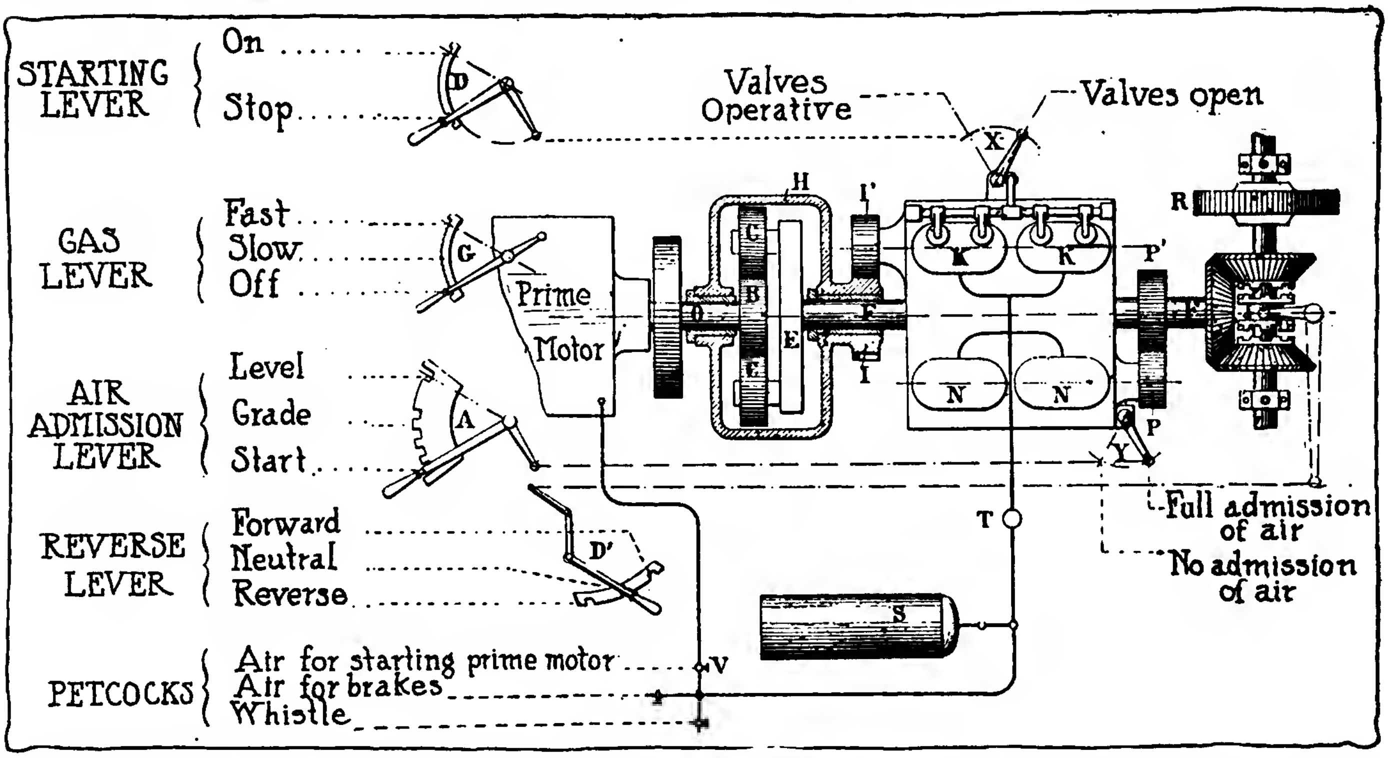

Fig. 2—Diagram of the Hautier system for power transmission at variable speed by means of air pumps, now applied to yard locomotive and suitable for motor trucks and omnibuses of large size

is to present a means for determining whether the fuel efficiency of a car falls short of the highest contemporary standard or not and that volumetric efficiency and the quality or adjustment of the carbureter DO enter indirectly, for their proper share among other factors in determining what value co-efficient sigma shall reach in each case.

The misunderstading must then have consisted in believing that Mr. Thomas had expressed himself to the contrary in his original article, where he wrote about the combination of factors entering into sigma: "This [the combination] not only takes into account the size of the motor and its volumetric efficiency, but also the state of perfection to which the carbureter has been brought." This sentence can be interpreted in diametrically opposite manners, by reason of the use of the indefinite term "takes into account". The tangle of understanding in the realities and misunderstanding of words can scarcely be unravelled now without extensive repetition.

If, however, the day should come when manufacturers would announce the co-efficient "K" and the co-efficient sigma of their cars, as they now announce their horsepowers on the basis of either formula or test or both, it would become important indeed to know that a low sigma—meaning a high fuel consumption—might be charged up against the carbureter, the size of the valves or the shape of the combustion chamber just as well as against sluggish wheel bearings, inaccurate gears and other sources of mechanical friction. A movement to popularize "K" and sigma in public announcements would, for that matter, be a very pleasing innovation and might perhaps lead to interesting results in the way of setting up rivalries of a new sort not only between manufacturers but also between car owners. The horsepower formula is widely understood; why not "K" and sigma? They are no more intricate to a veteran motorist than the tax-horsepower formulas of France or Germany are to a tyro.

—

INDUSTRIAL Applications of the Spray Method for Producing Metallic Coatings.—A number of corporations have recently been formed in Europe to exploit the Schoop metallizing process, from which fast of record it may be inferred that certain advantages of this method have been demonstrated, but it is not yet clear whether these advantages are the same as those which should interest the automobile industry. It is claimed (1) that the spray method is much cheaper than electroplating mainly because it is far more expeditious, (2) that the coating produced by it is firm and workable in any desired thickness and (3) that an aluminum coating is as readily produced as one of copper, zinc, lead or tin. These are among the results of the process which would appeal to automobile and accessory manufacturers if thoroughly substantiated. The possibility of cheapening and lightening motor castings by spraying the water-jackets into a paper form, afterwards cementing the joints likewise, and that of building radiators by spraying a strong and conductive metal upon a thin stamping of easily fusible material, representing what is going to be the hollow spaces and to be melted out, are attractive in theory.

The information relating to the whole process which was given at a lecture delivered in Berlin recently by a Dr. Lach may contribute to a sound estimate of the probable practical probabilities, and is reproduced in condensed form in the following:

The first patented spray method for metals dates back 30 years in Germany. Superheated steam was used for siphoning and atomizing molten metal. The Schoop method was begun on the same principle. The main progress was that heated gas as well as steam could be used and that much higher pressures were employed, causing a firmer coating to be produced. A portion of the gas or steam current was also used to force the molten metal by direct pressure into the path of the main current. The second stage was reached when it became understood that rapid expansion of the strong gas current in the atmosphere cooled the molten metal so effectively that it really was no longer in a liquid state when striking the surface to be coated, and that finely powdered metal therefore could be used just as well as molten metal. The melting of the metal could thus be dispensed with, which meant an important simplification of the apparatus. The third stage is technically and practically the most interesting, though it consists in abandoning the pulverizing of the metal and returning to a melting process, but this time an instantaneous one taking effect only the moment the metal is wanted and in proportion to the requirements of the work. The improvement was borrowed from the oxy-acetylene welding and metal-cutting practice developed independently in the meanwhile.

Glass and metal of high fusion point can after this last improvement be handled with almost the same facility as the baser metals. The apparatus now consists of three concentric tubes spaced apart. The inner one contains a wire, of the metal to be sprayed, which can be fed out gradually, and the other tubes serve as conduits for hydrogen and oxygen, respectively, both under high pressure, so that they flow out with great velocity. They are lighted, and the flame so formed melts the end of the metal wire which projects from the inner tube, atomizes this material and projects it with great force. If the heat of the oxy-hydrogen flame is insufficient, an oxy-acetylene flame can be produced instead, or an electric arc can be used by first melting the metal in it and allowing the drops to fall into the path of the gas current close to the nozzle. In practice the feeding of the wire to the flame is accomplished by actuating a small air-turbine by the gas, and the turbine then pushes the wire forward in proportion to the capacity of the flame for melting it, since the speed of the turbine and the heat of the flame both depend upon the gas pressure.

Whether the metal is blown upon porous material such as wood or paper or against a metallic surface, it is found that it enters in a very close union with the receiving surface, even to the extent of forming a metallic alloy in the contact zone. According to the nature and the preparation of the surface the coating can be made adherent and permanent or removable. The thickness can be varied, according to the duration of the exposure, from a few thousandths of a millimeter to 10 millimeters. Among the industrial applications of the process it may be mentioned that it has been found possible to produce a porous lead coating for storage battery plates. For the galvanizing of finished structures, such as bridges, and for objects with sharp corners where ordinary galvanizing does not adhere or get too thin, the advantages are obvious, the process taking the placing of painting in many instances by virtue of the hardness and permanence of the coating.

The electroplating work which can be done in one hour by the electric current the spray method can duplicate in one minute and without raising any question of the materials. Especially, coatings of aluminum which it has been found very difficult to precipitate by electroplating can be handled with precision and lasting results. Celluloid and balloon cloth can be metallized. The wood in ships can be protected against decay and insects. Explosives can be sealed up hermetically, which is of considerable importance, in the case of modern smokeless powders and other explosives, for the preservation of their properties and to avoid danger in their transportation on shipboard. Through the fact that removable coatings can be produced, the process attains a considerable importance in the art industries and for reproducing phonographic records, electrotypes for the manufacture of seamless tubes—the latter by spraying paper tubes with steel or any other metal of which it is desired to make the product. By twisting two wires of different metals together or by sending the spray from two apparatuses against the same object at the same time it is possible to produce alloys for experimental purposes in a very handy manner which admits of accurate variations.—From *Dingler's Polytechnisches Journal*, June 7.

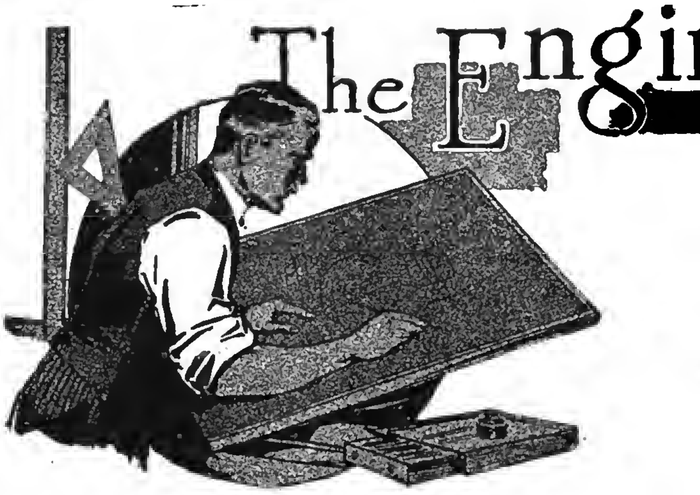
Automobile Statistics of the German Empire are presented in *Der Motorwagen* of May 31 giving the distribution of the different classes of vehicles in all of the states and provinces for the years 1907 to 1913 inclusively.

The Engineers' Forum



Defects in Springs

Part II

Emphasizes Shortening of Tire Life by Imperfect Spring Suspension

SEVERAL more interesting communications have been received on the subject of Defects in Springs, the discussion of which was opened by the comments of several engineers on the article by G. H. Baillee in THE AUTOMOBILE for May 29. Most of these communications, however, are too long to permit of publishing them this week. They will appear in the Forum in succeeding issues.

Good Springing Saves Tires.—Sturgis.

OAKLAND, CAL.—Editor THE AUTOMOBILE—We have read with much interest in your issue of AUTOMOBILE for May 29, the article on Defects in Springs.

The writer has personally been on the tire end of the game for about 10 years and during this time has seen a few changes in tires, but have not noticed any radical changes in the springs other than the difference in the metals used and less breakages at present than in the early stages.

As it is to-day the pneumatic tire has to absorb by far the largest of the shocks, and consequently the life of tire is comparatively short. It has come under my personal observation a number of times that cars with the stiffest springs are those that the tires wear out rapidly on, and necessarily, of course, give the greatest amount of trouble.

The tire man would welcome more flexible springs or pneumatic suspension of the chassis. As it is to-day, the tire man has his troubles, and plenty of them.—V. K. STURGIS, Pacific Leather Works.

Why Not Hold Accessibility Contests?—Duryea.

SAGINAW, MICH.—Editor THE AUTOMOBILE—I have read the remarks of Lee Day in the Engineers' Forum, regarding accessibility and demountability, with much interest. I second his attitude strongly. It does seem odd that the public pays so little attention to such vital features. The only explanation that seems to be in sight is that the makers dare not submit their cars to tests of accessibility. They make a big talk about reliability, and more or less about accessibility, but an accessibility contest has not been held so far as we know. It is a well-known fact that the factory cost of a repair part is generally very small, but the cost of getting it into the vehicle is a very expensive item. The public in time learns this. but has no real method of knowing whether the next rig it buys is any better or not, and so long as attention is not given to these points neither the public nor the makers do much toward making them better. There is a big hullabaloo about many details of no particular importance, but this one of accessibility for purposes of attention and repair is sadly neglected.

There are enough experienced users of automobiles in the world to-day to make an accessibility contest a very interesting affair. These experienced men know something about the troubles of adjusting and repairing, or replacing any given part, and if our various exhibitions or contests should include one or more accessibility trials, the good to the industry would be immense and immediate. It would accentuate for the maker a valuable feature, and it would certainly please the user. Each contestant should be allowed to furnish his supply of tools, but they should be listed, and their weight, bulk and selling price stated. The vehicle should be driven and inspected so as to know that it is in running shape, all parts being present. Then in the presence of the spectators, and previously unknown to the contestants, a certain repair stunt should be required. That is to say, remove the power plant, or remove the piston, or any other vital part that in actual practice may require removal. The time required to accomplish this should be taken, and also the time required to replace it. Then the car should be again driven and inspected.

The maker does not see this thing from the user's standpoint. He is prepared with appliances for lifting off the body or separating certain parts of the car, that the user does not have, and to his skilled men a job that may be inherently difficult does not strike them as being such, but when this work must be done away from the factory with few appliances, and generally with but one or two men, the problem becomes entirely different. A task that was not disagreeable on a brand new machine, perfectly clean, and with every appliance, becomes a very disagreeable problem when performed as the user performs it on a dirty machine, and without the necessary tools, as often must be done.

While suggesting contests, I would like to further suggest coasting contests. In these days of high-priced fuel everybody should be interested in economical running, and the car that runs most easily is the car that requires the least fuel. Of course different size cars should require different quantities of fuel, and therefore the best test available is the one which will select the most easy running car in proportion to its weight. This a coasting contests shows at once. If every user could select a hill on which he can frequently test his car as to its coasting ability, he could always know whether it was running with its accustomed freedom or not, and therefore know whether he was burning more fuel than he should, or not. A dragging brake band is responsible for much engine trouble, and a coast over a known surface will show whether or not the brakes are as free as formerly. The same thought applies to bearings that may not be properly oiled, or that may be badly worn, to tires that are not properly inflated, and many other points. The coasting contest has the elements of a contest in it, and the public like to see one rig surpass another, so it could be made an interesting thing, possibly in conjunction with a hill climbing contest. For actual test purposes, however, some sort of towing test would serve the same purpose. Every owner should know how many pounds are required to tow his car on a floor or level road, and by occasional testing he could know its running condition. It is a sad commentary of our modern automobiles when three or four men are required to push one about in a garage, as is frequently seen to be the case. It should be evident to anyone that if this much power is necessary, the unfortunate engine must use much fuel in order to overcome a lot of needless resistance.—CHAS E. DURYEA, President Duryea Motor Co.

Keeping Track of Tires

Sales Records and Other Forms Help Dealers To Keep a Record of Cost, Use and Other Items

TIRE manufacturers have devised special cost-keeping systems for their dealers, not only in the matter of repair work, if such is done by the dealer or a factory branch—which, however, is a rare state of affairs—but also for making exact records of all sales of tires. To avoid all misunderstandings from the beginning, let it be said here that this is not done to record the owners of a casing number so and so, but merely in order to keep up-to-the-minute statements of the companies' business on hand and to keep the factory posted on how the sales organization is progressing, thereby giving it a direct opportunity of gauging the future requirements of a certain territory.

A number of the sales record forms used by the New York representatives of some very prominent tire makers are here shown, these being the Goodyear, Firestone and Michelin concerns. The sales record Fig. 1, of the Goodyear Tire & Rubber Co., 10.5 by 6.5 inches, is filled out by the salesman closing a tire sale, and two carbon copies are made at the same time with the original record. The original is light blue, the duplicate yellow and the triplicate pink. All three copies bear the same number, each set of three forming part of a series of consecutively numbered blank sets.

In making out this record, the salesman fills out the names and addresses of the parties ordering and receiving the goods, the terms on which they are sold, his name and the class of the customer, that is, consumer, dealer or special dealer. This having been done, the three copies of the order are sent to the stockroom, where the foreman sees that they are properly filled, after which goods and order proceed to the shipping department, the person who took the goods from stock having signed the order under "Assembled By." The shipping clerk also signs the order and notes on it the number of the invoice and the bill of lading or receipt obtained when the goods were sent out.

Then the set of three copies is sent to the office of the manager, where the blue original is filed with preceding originals, in numerical order, while the yellow copy is filed in a folder marked with the buyer's name, all folders being arranged alphabetically. Thus a cross indexing scheme is operative between originals and duplicate orders and it is easy to get at one or the other, provided the name of a customer or the number of the order is known.

The pink triplicate, which is only 7.5 by 6.5 inches, is sent to the Akron factory. On its reverse side are spaces to be filled out if the order is filled by and by, these spaces being for the date of the shipment, the invoice number, quantity, size and weight of the goods and the name, that is, casing, tube, inner liner or what else it be.

A different form serving the same purpose is used by the Michelin Tire Co., Fig. 7. This form is 11 by 7 inches and is made out in four copies: White, original; yellow, duplicate; red triplicate, and white, quadruplicate. The use of these blanks is peculiar, due to the fact that all large shipments are made not from New York but from the Milltown, N. J., factory, and that the blanks are used not only in case of sales made at the branch and filled there, but also when orders are to be filled from the factory or goods are to be shipped to the Metropolitan branch. In this case, the original is sent to Milltown, without any prices marked on it, while the duplicate, upon which prices appear, remains in the book of the branch. The triplicate, destined to be given to the customer when the order is taken, is not used but destroyed when the branch orders stock from the factory. The fourth copy is sent to Milltown with prices marked on it. The factory files the unpriced records in order of the

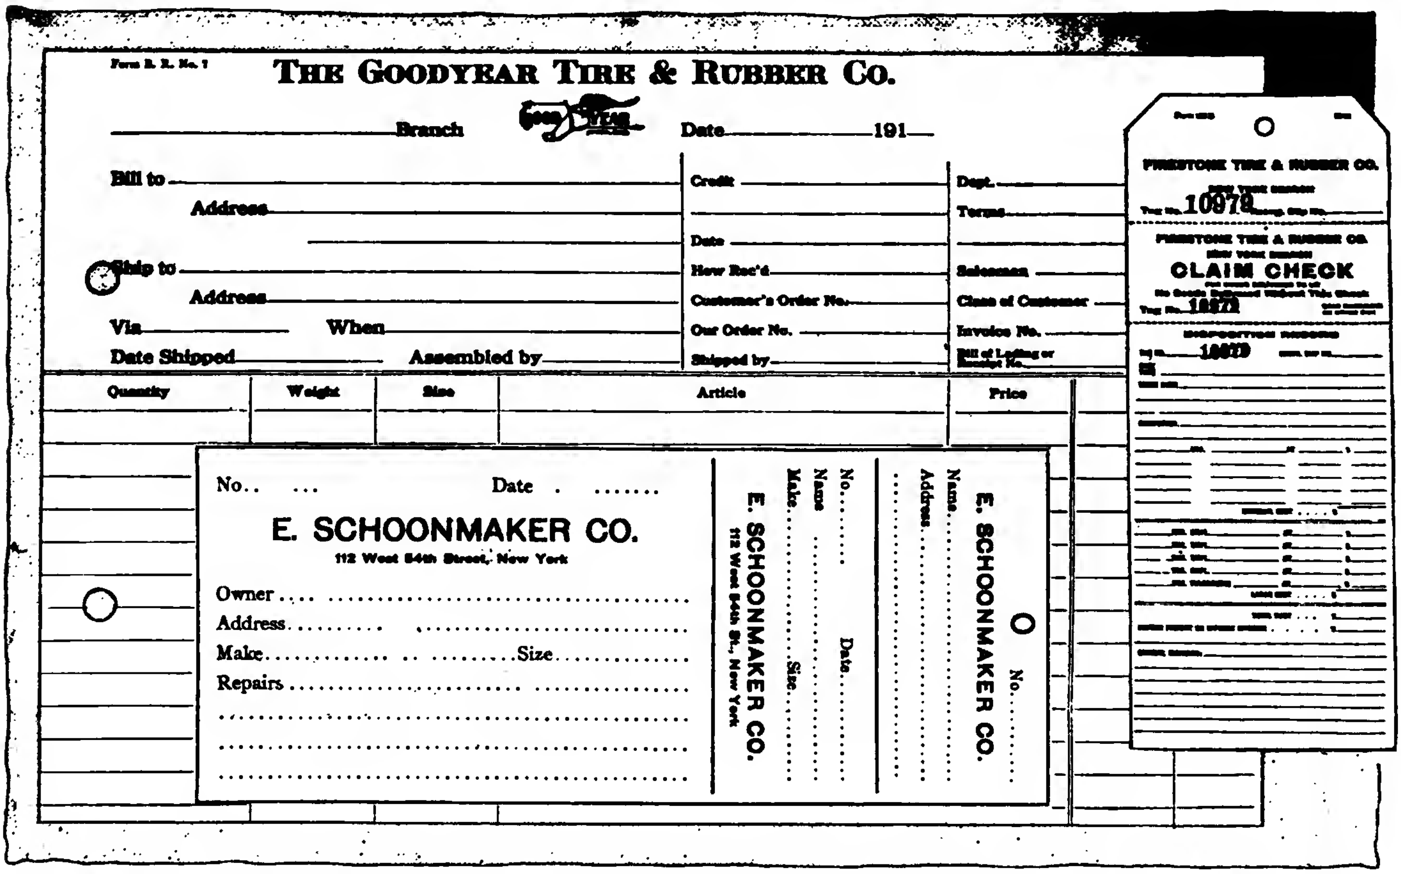


Fig. 1—Sales form of the Goodyear Tire and Rubber Co. Fig. 2—Work order, claim check and adjuster's slip of the E. Schoonmaker Co. Fig. 3—Adjustment form of the Firestone Tire and Rubber Co.

dates and the priced ones according to names of the customers.

When a sale is made and filled at the branch the stock clerk retains the first copy as a receipt for the goods issued, the priced duplicate remains in the book in the office, the triplicate is priced and delivered or mailed to the customer and the quadruplicate is returned by the shipper to the branch billing department.

The Firestone Tire & Rubber Co.'s form is shown in Fig. 8. It is 8.5 by 11 inches, and is issued in triplicate, being numbered. The yellow original, when all spaces have been duly filled in, is filed under the customer's name, in the same way as in the case of the Goodyear system; the white duplicate is filed under the number and the triplicate, printed on thin cardboard is packed with the goods at the time of shipping.

The repair room systems vary with the companies using them. It must be said in this connection that the majority of companies represented in New York City have no repair departments, but send all repair work to be done to reliable outside shops and charge the customer with cost. Among the few exceptions which have their own repair shops, is the Firestone concern. Fig. 3 shows the form used by this company in handling its adjustments. The form consists of a tag composed of three sections and 3.3 by 8.5 inches in size. All three sections are stamped with the same number. The top section serves as receiving slip, filled out by the adjuster with a serial number when the tube or casing is received for repair. On the bottom section the work to be done is named with all the necessary detail, and space is provided for recording the work spent on the repair job. The middle section or so-called claim check is given to the customer bringing in the tire and it is taken from him in exchange for the repaired product when the latter is delivered to the owner. The receiving slip is filed away by the adjuster

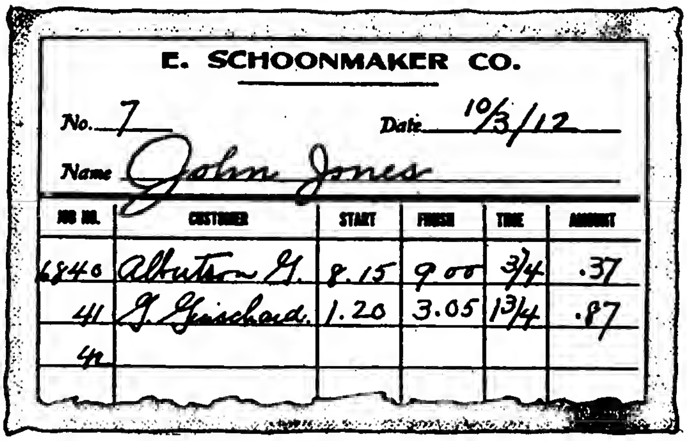

Fig. 4—Workman's time distribution card used by the E. Schoonmaker Co.

under the customer's name as soon as the repair has been completed. When the tire had been delivered, both work order (bottom section) and claim check, which are fastened together, are filed away under the customer's name.

As the example of a large company doing contract repair work for big tire dealers in the Metropolis, the E. Schoonmaker Co. may be mentioned here. Its system uses three forms, a time distribution record, a materials-used record and a card serving the same purpose as the Firestone card just described. Fig. 4 shows the time-distribution record used daily by each workman. On the form he enters the number of the repair job, the name

(Continued on page 1311)

General Inspection

From Paper Read Before the S. A. E. and Visiting Engineers by E. F. Roberts

THERE is no more positive evidence of the general desire among American manufacturers today to deliver to the buying public a dependable product, honestly made, than the general interest in inspection methods. There should be no more satisfying proof to the buyer of a motor car that the vehicle represents the utmost possible limit of safety for himself or his family than the knowledge that its construction has been safeguarded at every step, from raw material to finished assembly. The progressive manufacturer realizes that the only assurance of permanent prosperity lies in the excellence of his product; and eternal vigilance is the price of excellence. Inspection, close, constant and rigid, is thus imperative to maintain the quality in the product and, although when adequately inforced, one of the most costly features of a motor car organization, it must be recognized as one of the most vital. Realizing structural strains at the average speed of a powerful car and the gravity of possible flaws or breakage, it is obvious that to the purchaser the most essential consideration is the certainty that every detail of material and construction has been subjected to the most severe and searching test that skill can devise for his protection. Absolute interchangeability of parts is also an essential for rapid and economical production and modern inspection with quick-acting gauge systems constitute the indispensable factor of attaining this result.

In large industries, perhaps the first feature that should be considered in an inspection system is the relation of its personnel to the rest of the organization. To secure the determined and inflexible adherence to the standards of quality and workmanship laid down by the management, members of the inspection department cannot be in any degree subject to the control of any shop foreman or any executive directly producing. Evidence to this effect is so common to the experience of all factory executives that the principle scarcely needs mention, but its expression is justified by the fact that in spite of this, scores of organizations either through ignorance of their own situation or indifference permit such conditions to remain. It is an emphatic axiom that the average workman thinks of his job first and duty afterward; and an inspector refusing to pass defective work for a foreman who can discharge him is, commercially, an imaginary quantity.

Six Divisions

For convenience of administration the Packard plant is organized into six productive divisions designated as Chassis, Body, Truck, Forge, Foundry and Service Divisions. Each division constitutes a unit in itself, not only as regards productive organization, but also as concerns its inspection force. Each division's inspection corps is in charge of a general head and over all the divisions extends the authority of the chief inspector. This executive is responsible directly to the general superintendent, is personally a thorough and experienced mechanic, familiar with general engineering practice, standards and limits, and also an expert as regards manufacturing conditions, gauge systems, tool design, etc. With his assistant and through the division heads and foremen inspectors in charge of buildings and, in some cases, large departments, he is in direct control of every inspector in the plant. Foremen inspectors may to a limited extent perform actual inspection work, but their duty is essentially that of maintaining the efficiency of the men and methods under their supervision. They must be actively watchful of the care used in checking parts, must see that all parts brought up are handled promptly and that gauges and instruments are properly used, and, above all, kept continuously in first-class condition. Through their personality the policy and standards of the entire inspection system must be impressed upon every individual in it and the quality of their department output is a standard for which they are directly responsible. Regular department foremen may report infractions of discipline by inspectors and have prompt action taken by the chief inspector, but individual inspectors in departments are wholly free from any constraint in criticizing poor workmanship. Every operation and every part is passed or rejected absolutely upon its conformity, or lack of it, with the blueprint. There are large placards conspicuously posted in every department warning inspectors that immediate discharge will result from passing work on any other basis, except written authority of a general executive. Every possible means is thus employed to impress upon the inspectors that their sole responsibility is the maintenance of quality, and that their positions depend upon this and nothing else. An inspecting force, although necessarily recruited from various sources, should consist mainly of men of previous experience and training in other mechanical departments of the plant. All inspectors should further, when first assigned to this duty, be placed in company with an experienced man and their work carefully watched for a number of days before giving them individual assignments. Special care should be exercised in selecting and examining them, they should be well paid and every possible effort made to hold satisfactory men permanently on the line of work in which they have become expert. A graphic organization chart is herewith given to indicate the relations of the various branches of the Inspection Department.

Limits

The function of an efficient inspection department should begin even before the drawings are approved in the engineering department. The chief inspector should be *ex officio* chairman of the limit committee, whose duty it should be to pass on all drawings to determine whether the limits assigned by the designer are commercially practicable, thus ensuring the elimination of many possible sources of later friction and delay. After the drawings for a new design are approved and signed by the limit committee, and not until then, they should be issued to the various functional divisions, the set in which the inspection department are interested being those sent to the tool room. These, of course, should be checked over to determine the new tools and fixtures required—and also on the inspection department's behalf—to determine the new gauges necessary, preparation thus being under way for the inspection of the finished product, in some instances, even before the raw material is ordered.

Material

Material, as will be noted from the chart, should be for inspection purposes divided into raw stores, including bar, tubing and sheet metal; car parts rough, comprising castings, stampings and forgings; body parts rough, such as lumber, leather, glass, trimming fabrics; and car parts finished and semi-finished. To insure uniformity of composition and quality all metals should be bought on the basis of standard analytical specifications, developed by the engineering department through laboratory test and research. Supply firms, before making up an order, should send in sample test pieces for approval, insuring in this way almost invariable conformity with the specifications and eliminating delays and arguments. In the case of ordinary bar stock, as soon as a consignment is received and checked in as per invoice, it should be inspected for size, limit snap gauges being used and each end of each bar being checked. Straightness also should be noted, as occasionally a bar may be found that would not pass readily through the machine collets. A bar should then be selected at random and a test piece 3 or 4 inches long sawed off. This should be tagged with the date, amount of consignment, grade of metal and the purpose used for, and forwarded to the laboratory for analysis.

The laboratory is exceptionally complete and well equipped for analytical and physical research. It is in charge of a chemist and engineering specialist of wide experience; and every imaginable determination required in industrial engineering can be covered in this department from the crystalline structure of the antimony content in crankshaft bearings to the tons of pressure required for the breakage test of a front axle. Special rush service can always be had from a laboratory of this description in 12 hours, although ordinarily 2 days are allowed. As soon as the test piece has been removed, each bar should then have the grade number and date stamped on the end and the consignment should be placed in the regular rack pending receipt of the laboratory release. After analysis the duplicate stub from the specification tag will be removed by the laboratory and returned to the stock department, thereby either releasing the consignment for factory use or rejecting it as unfit. If the analysis is satisfactory, the stockkeeper should then paint the ends of all bars in this lot with the standard color for that grade, indicating its readiness for use. To ensure this method being given proper attention, personal instructions must be issued, and as a further precaution, signs be posted warning the men that painted ends must never be cut off and that all bars must be placed in the racks, painted ends out. If the laboratory analysis shows the sample below grade limits, the stock department should notify the purchasing department and arrangements should at once be made either for the return of the consignment or is substitution for any other use for which it may still be fit. Bar stock intended for special use, such as piston pins, universal joint pins, etc., or selected stock, should be kept in special separate bins.

The same general method should be followed in the inspection of tubing except that it must be checked for inside diameter or thickness of wall, as well as outside diameter, and also for eccentricity. Standard sheet metal, aluminum, brass, copper, steel galvanized sheets, etc., from established firms need ordinarily be checked only for gauge and general appearance and accepted without analytical test. In the case of stamping stock, however, a test strip 1.5 by 12 inches should always be submitted for analysis and tensile test. In such instances the same procedure would be gone through with as in the case of bar stock, except that a different method of marking (surface stamping) must be used.

For ensuring the correctness of forgings the regular practice should be to submit a lead proof for a preliminary check before the dies are hardened. The lead as soon as received should be delivered to the purchasing department for record and forwarded by them to the engineering department for general checking as to design specifications. If satisfactory it should then be transmitted to the tool department, where it must be laid out and carefully gone over in detail with the drawing, and this opportunity should also be improved for comparing it with the design of any fixtures and gauges relating to this part. As soon as this check is completed the tool room inspector should immediately advise the purchasing department as to approval or rejection. If approved, as soon as delivery of forgings begins, a few of the first may be selected at random and again checked over in every detail to cover any possible deviation on the dies or negligence on the part of the operator. Important parts subjected to heavy stresses, such as axles, steering levers, steering knuckles, steering worm, transmission gears and parts, should invariably pass the analytical test for every consignment also before being released.

Checking of Patterns

Patterns for castings should in every instance be closely checked by a special inspector before being released for use, thus eliminating chance of error as much as possible, in the initial state. As soon as the first casting from any pattern is completed it should be at once forwarded as a test sample and submitted to the same inspection and detail checking as that given forgings and the same routine may be followed in rejecting or accepting it and approving delivery. In the foundry test bars are run from every melt and regularly analyzed and tested for physical properties. Individual castings are inspected in detail as received, although not laid out for every operation. In general casting inspection cored holes and bosses should, however, be checked to discover any possible variations due to core shift and the entire casting should also be carefully scrutinized for sand or blow-holes. Doubtful places must be tapped with a hammer, or, to determine leakage, tested with gasoline. The scleroscope test may also be employed in case trouble is experienced on account of excessive hardness. Stampings should be covered by an initial inspection practically the same as that given forgings, except as regards tool work, since they are usually a finished product when received, requiring ordinarily only a polishing, enameling or similar operation. Such exceptions as do require machining to any extent must be given the same thorough checking and testing that the forgings are subjected to.

Body stock should be also inspected, the lumber being scaled and examined for quality and soundness, while leather, cloth, glass, etc., should each be checked over by experts in these lines. Paints, oils and varnishes should be bought both on analytical and weathering tests and a year's exposure to sun, wind, rain and sleet is none too strenuous a test for body varnish. The passing of all finished parts, from miscellaneous supplies and tools to occasional car parts bought finished, should also be within the jurisdiction of the inspection department and conducted with the same unvarying fidelity to standard quality and specifications as observed in regard to all other items. The essential features of an efficient material inspection are, first, that nothing must be left to the individual judgment or opinion of the inspector. Every specification should be based on the most thorough engineering or mechanical research and embodied in drawings or written instructions. The second and equally important consideration is that the inspectors must absolutely be under no constraint as regards considerations of production. However badly the factory may need material or parts, the receiving inspector must recede in not the slightest degree from his standards. He is paid and must be held responsible for the maintenance of quality alone. Production to him should be a matter of absolute indifference.

The foregoing methods and regulations for the inspection, analysis or test of all stock and parts entering a plant are intended to and, we believe, do guarantee the quality and fitness of every item of material comprised in the car. Perfect material is, above all else, the requisite of first importance. Poor workmanship may spoil good material, but no amount of good workmanship can ever redeem poor material.

Factory inspection of parts in process in a large organization can be best conducted almost entirely on a departmental basis. In a small plant a central inspection department possesses certain advantages, but with the growth of any business, the time required for trucking and handling must eventually make this method obsolete. In each department a central location should be selected, well-lighted and convenient, and here at inspection plates should be installed the head inspector and his assistants. The inspection plates used in the Parkard factory are of cast iron, 24 by 57 inches, and of massive and rigid construction. They are planed and finished on top to an accurate surface and carefully used and looked after, being covered every night with a coating of oil and frequently tested for trueness. At these sit the inspectors, provided with blueprints covering every part handled in the room and with standard or special gauges for checking every operation; and to them are brought all the various lots of parts as fast as completed in each operation.

Gauges

The greatest factor in quick and thorough inspection is an efficient system of gauges. There is no more common fallacy in manufacturing than the assumption that a correct set of gauges once issued insures accuracy of workmanship. And a pretty general fallacy is the assumption of correctness for the gauges themselves. Ordinarily the micrometer is accepted as the standard of measurement. When, however, it is remembered that the average micrometer will alter merely by the heat of the hand to an extent of two ten-thousandths, it is obvious that the court of final appeal for accuracy must be a higher one. There can be no more absolute precision standard than the Johannson system of gauges. A set of these gauges consist of eighty-one blocks, increasing in size by graduations of one ten-thousandth of an inch. They are manufactured in Sweden, the completion of a single set requiring about five years and the surfaces when finished being so perfect that atmospheric pressure will hold a dozen of them suspended in a cluster from one held between the fingers in the same manner as though magnetized. In addition to their almost infinite accuracy they are so impervious to variations of temperature that one of them may be carefully checked in a warm room with the most sensitive instrument possible and then after being laid on ice again checked without showing the slightest variation. These gauges may be accepted as the final source of authority on the accuracy of all manufacturing dimensions. They should serve as the check for all master gauges, which in turn check the shop sets. Special gauges, of course, must be designed in the tool draughting room as soon as the original design of a new model is issued. Standard gauges, however, are required in such large quantities and the efficiency of any inspection system is so dependent upon their immediate accessibility that standard blanks for snap, plug and ring gauges should be carried in stock at all times. These may be made up rapidly and at low cost principally on automatics, leaving only sizing and finishing operations for the toolmaker. This method renders gauge equipment so readily accessible that there is no incentive or excuse for negligence in this respect. All rough stock sent into the factory in dimension lengths should be cut to gauge in the stockroom. The workman who machines it should have a gauge for his operation which is a duplicate of the inspector's. The inspector's gauge is thus a check on the accuracy of the workman's, and all the inspector's gauges should be in turn checked at regular intervals with the master gauges held in the tool room. Too much emphasis cannot be placed upon the importance of properly checking and caring for the master gauges. The set should be at

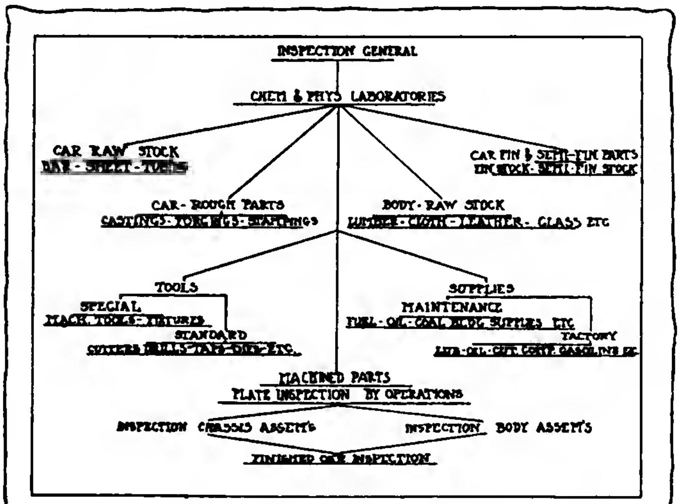

Diagram illustrating the general scheme of inspection least sufficiently complete to cover every important part. They should be given not less than three different checks with the Swedish master blocks by three different inspectors and these separate readings reconciled before being approved for use in the first place. They should be kept in vaults under lock and withdrawn only on fixed occasions or by some executive's order and then only by the man or men regularly assigned to the duty of handling them. No attempt should be made to use them indiscriminately for checking shop gauges, as their function should be the control of the inspectors' gauges only. Every gauge in every department should be turned into the tool-crib at the close of working hours. Some of the more important ones must be checked daily before issue and very few should be permitted to be used unchecked for more than a week. Limit thread gauges in particular must be checked with the master gauges every few days for accuracy of dimensions and depth of thread.

Gauges Must Be Sized

All gauges must be sized to the limits shown on the print and only parts coming inside these limits passed. Parts outside the limit, except where the defect is a nominal one only, such as oversize, may be sent at once to a central checking station. All parts received here should be examined daily by the chief inspector or his assistant and the division superintendent or his assistant. The reason for the defect should be clearly determined and if tools are at fault the proper correction at once made. If, as is usually the case, the cause is negligence on the part of the operator, the foreman's attention must be called to it and both he and the operator warned against a repetition. In the department itself, the inspectors, as soon as a defective lot of parts appears, should issue to the foreman a written "stop-notice" or warning that a certain operator or certain machine is producing work below standard. This will insure immediate attention, as it puts the responsibility squarely up to the foreman. When all the operations on a given part are completed in one department, the inspector's O. K. should be again required before they can be forwarded to the next one. There is no possibility under the Packard method of any lot of parts accidentally escaping inspection. The operator's pay, for every lot and every piece worked on, is absolutely contingent on the inspector's O. K. and every workman for this reason is continuously watchful to prevent negligence on the part of his department inspector. Even dishonest inspection has little incentive since the time-slips on file bear so complete a record that the responsibility for such work may be very easily determined. Thus at every step in the progress of a part it is possible to so check and safeguard it as to ensure its conformity to the standard of quality. To illustrate in detail a thorough method of supervising the maintenance of inspection standards, we may follow the development of a typical forging, the bevel driving gear, as carried through its various operations in the factory. In one respect this gear is given special inspection by receiving a supplementary analytical material test. The steel from which it is forged is given the regular laboratory analysis before being released to the Forge Division, but, in addition to this, because of the importance of the part in regard to both strength and quiet running, a material test is taken on each lot of forgings received. Chips are removed from a sample, and analyzed, and the whole lot are held until the result of the analysis is known. The blanks after release are heat treated and then sent to the lathe for boring and reaming the larger opening for the differential casing and turning the face of the web. The blank is then sent to the plate and the dimensions and surfaces checked. The piece is next taken to the milling machine and the four slots for the differential spider are cut. For the second time it goes to the inspector, to determine whether the slots are central, at right angles to each other, square with the surface of the web and true to size within a limit of one half-thousandth plus or minus. Next the outside diameter is rough-turned and the face angle finish-turned, making necessary the third trip to the inspection plate. Again the blank is sent to the lathe for finish-turning the outside diameter and the back angle and sizing the width of the tooth plane. This makes necessary the fourth inspection, after which, if passed, it is sent to have the face of the tooth-plane ground to the correct angle with the web. For the fifth time an inspector checks it before it is passed on to have the back of the web surfaced preparatory to copper-plating for hardening. After plating the teeth are rough and finished cut, which makes necessary inspection No. 6. The gear is next sent to the heat-treating department and first pack-hardened or carbonized. In the carbonizing pot along with each lot of gears is placed a test piece of the same material as the gears, about 6 inches long and .5 inches square. After the specified interval for this grade of steel, the gears and test bar are removed, cooled and reheated for hardening. After hardening they are cleaned and the test bar is broken and checked for depth of case, fineness of grain and general structural appearance, as an index of the internal condition of the gears. The gear is now ready for the most important of all its inspections, the strength and hardness test. Hardness is measured by the scleroscope, which compares the condition of the part with that of a standard established by the Brinnell testing machine. Between thirty and forty readings are taken from each gear. Strength is determined by the hammer test, a device which permits the concentration of a heavy blow of known force on a single tooth, each gear being given this test on at least four different points in its periphery. These tests may be considered as inspections Nos. 6 and 7, and are immediately followed by inspection No. 8, which is the test applied by a special fixture for determining the amount of possible distortion due to heat. This inspection is rigorous and minute, covering every tooth of every gear; and the gear that checks two-thousandths of an inch eccentric on the pitch circle is rejected. The diameter of this circle is 13 inches, but the limit of variation that any gear can show and pass is only one and one-half thousandths of an inch.

When successfully past this inspection the gear is ready to be ground on its outside diameter and on the face of the teeth and this in turn leads to inspection No. 9. Another grinding operation on the back and face of the web and again an inspector must check the accuracy of operator and machine, this time permitting a limit of variation of only one-half-thousandth. The final grinding is the finish of the opening for the differential case, which is followed by inspection No. 11. The last machining operation is the drilling and reaming of the differential casing bolt holes, which, in inspection No. 12, are checked for size and spacing. Absolute conformity to specifications is the standard for this operation, no variation being permitted. Not yet, however, may the gear be released as a finished part, as it may still fail on No. 13, the final inspection. This consists of a test on a special fixture again, for checking the correctness of the tooth-bearing and smoothness of roll, and but little less than perfection is required of the gear that is finally passed through. As a finished product it is obvious that a large percentage of the cost of the gear is due to the continual supervision of the inspector, but it should also be equally obvious that the result is an article as near to the ideal of mechanical perfection as the best of equipment, skill and scientific testing can achieve.

Assembly Inspection

In addition to the parts inspection, which should cover every item purchased or made for the car, all assemblies from the gasoline tank draincock to the motor should be checked in detail, both for accuracy of relation of their parts and for operation. The minor assemblies must be checked by themselves and then later as parts of large assemblies will again be inspected for location and function. This progression should follow through all the various stages of assembly, culminating in the motor, for instance, in the motor test room, where the engine, speeding under its own power, may be checked for every phase of construction and efficiency by its showing in operation under full service load. As a part of the chassis assembly it is again due to be checked, along with the others, for perfection of adjustment in the chassis road test. Bodies should be inspected—in the beginning, part by part—wood, glass, leather and cloth. Before entering the paint departments every one must again be gone over inch by inch and every minor defect, whether dent in aluminum or check in wood, sought out and corrected. Another inspector will pass it from the paint shop into the trimming department, and an expert trimmer's inspection O. K. should be required to get it from this department back into the finish varnish room. Before it is sent down to be attached to the chassis it must be given a last careful scrutiny for any possible defects of finish or workmanship, and in the finished car assembly department meet a chassis, which has come through only after a similar ordeal in its own paint department. After the car is assembled it should be inspected and checked with the specifications on the sales order for completeness and workmanship before being passed to the finished test department. Preparatory to the road test the motor is to be tuned up to the finest possible pitch of adjustment and inspected for quietness and flexibility before being turned over to the driver. As this test covers road performance it should be entrusted only to men of long experience and special aptitude and judgment. If passed, there remains only the attaching of any special equipment or accessories and the formal checking out of the car before submitting it to still another inspection, the most severe and critical of any it has endured. The sales department should have charge of this feature and their attitude should represent as nearly as possible that of the buyer. Not being subject to the control of discipline of the manufacturing department in any degree, they are free to exercise their judgment without fear or favor on every detail of construction, operation and finish. Their decisions are positive and final, and the car that, in their eyes, falls short of the desired perfection is rejected until brought up to this ideal.

Weaver Opens Discussion

The discussion was opened by E. W. Weaver, Peerless Company, who stated that he has given considerable study to this phase of manufacturing. In connection with that part of the paper dealing with selected stock, the question was asked as to whether this referred to the Packard company's own inspection or to the fact that the stock was bought selected from the steel maker. The latter was meant.

Henry Souther touched upon the inspection of material and pointed out that such inspection is a very important part of the manufacture which must not be dropped out no matter what other inspections are eliminated. The greatest damage is done by the purchasing departments in not ordering their materials far enough ahead so as to get proper inspection. If the stock is received enough in advance, it is possible to hold it up until its exact identity can be determined, thus preventing any inappropriate material from being used for the various parts.

F. E. Moskovics asked as to what relation the physical laboratory plays to the inspection methods, to which Russel Huff, Packard, replied that this laboratory has been practically turned over to the manufacturing department. The whole plant depends upon this laboratory for its specifications for materials for different purposes. These specifications are spread around the factory for the different departments in such a way that all materials are ordered in accordance with them. There is a regular form for handling the inspection in a routine manner. In this way all departments know just what kind of material is in a carload, as to its carbon content, and so on.

C. F. Fuller, Wayman and Gordon Co., emphasized the importance of testing for the physical properties of bar stock materials and forgings. He cited an example of a broken steering knuckle which came to his attention. Although the material of which it was made had the proper chemical constitution, its physical properties were absurdly deficient. This shows that it is necessary to test whatever you get, for although manufacturers can furnish the properties desired, they very often furnish materials which do not meet the requirements.

Wheels for Commercial Vehicles

From a Paper Read Before the S.A.E. and I.A.E. by Arthur J. Slade

THIS paper is the outcome of the writer's temerity in offering a suggestion to the Commercial Car Wheels Division of the Standards Committee, that, in considering the standardization of metal wheels, along lines similar to the standardization of wood wheels, certain practices, as to material and design, should be recommended for the benefit of the motor truck designer.

A precedent has been established by the Iron and Steel Division of the Standards Committee, in recommending good engineering practice; as for example:

"Steel castings for axles, crankshafts, and steering spindles are used only at a great risk."

The chairman of the Commercial Car Wheels Division, and the secretary and general manager of the society, did not, however, view the proposal with approval, but suggested a paper for presentation at this meeting, with a view to bringing out available information as to suitable material and designs for truck wheels, through those members best qualified by experience to express themselves on the subject with authority.

It is perhaps natural that wheels built of wood should have been developed to a high state of perfection in this country where such a large and varied supply of wood is available. The rapid development of the West called for vehicles of rugged and sturdy type for the pioneer's use in opening up a country without roads of any sort. Later the transportation companies, operating stage coaches over roads little more than trails, as new sections were settled, and eventually the agriculturist, who even now often operates his farm wagons over roads unworthy the name, demanded the highest quality of wheels.

The majority of the motor trucks built in this country have been equipped with wooden wheels; the earlier wheels conforming closely to the design of horse-drawn wagon wheels, especially with regard to size of spokes, but also, in some instances conforming to wagon-wheel practice even to the extent of wooden hubs. Some of these wheels, dating back perhaps 10 or 12 years, are still in service on motor trucks in New York City.

Development of Wood Wheels

The first radical improvement was in the substitution of metal for wood hubs, primarily to make possible the use of anti-friction bearings. Next came a radical change in the matter of spokes. When it is considered that a wagon wheel on a 5-ton capacity vehicle seldom has a tire exceeding 4 inches in width, whereas the tires on the 5-ton motor truck will usually total from 10 to 12 inches in width, it becomes obvions that the wide felloe on the truck wheel should be supported by a spoke of much greater width than the narrow felloe of the wagon wheel. Since 1907, when the importation into America of one of the most successful European trucks began, the improvement in the design, as well as construction, of wood wheels has been very marked. At that time one of our leading wheel builders undertook to practically duplicate these European wheels with spokes about 5 inches in width, flaring at the onter end so as to form an adequate support for the felloe, and also of sufficient cross-section to insure a good shonlder on the end of the spoke against the inner surface of the felloe. Ever since that date the wheel builder in question has been manufacturing wheels, from designs similar to this, with great success; and, although some other wheel builders contended at the time that it was not feasible to procure wooden billets of a size suitable to finish spokes of such unusual dimensions, the majority, if not all, of the wheel builders catering to the motor truck industry are now building wood wheels of this general type.

Early Metal Wheels

It must not be assumed, however, that the practice of motor truck builders in this country has been confined exclusively to wooden wheels. As far back as 1858 and 1862 motor trucks are reported to have been built, in an experimental way, with steel wheels. In the years 1903 and 1904, when the motor truck industry in this country was making a definite commercial start, the Gibbs Engineering & Manufacturing Co. equipped trucks with cast steel and steel disk wheels. The cast steel wheels were similar to those now being advocated by several manufacturers, having hollow spokes integral with hubs and felloes. They were made of crucible steel and used a tire constructed from a combination of wood, steel and rubber. About twenty 5-ton trucks were built and the wheels were found to be on the whole satisfactory. The disk wheels were made of boiler plate, riveted to cast steel hubs and to a steel tire band. These wheels were also said to have given satisfactory service, but the company building the trucks in question no longer exists. One of our members who was identified with the production of these vehicles will, it is hoped, contribute some discussion on this paper.

In 1905 the Couple-Gear Freight Wheel Co. brought out a line of trucks equipped with wheels made up of steel plates. In the interior of the wheels an electric motor was mounted, and this same construction has been followed by that company up to the present date. At about the same time the Four-Wheel-Drive Wagon Co., of Milwaukee, brought out 5- and 10-ton capacity gasoline trucks equipped with wheels on which the tires were segments of rock elm and the side plates were steel disks. This company is not now in existence.

In 1906, a metal wheel, known as the "Indestructible Steel Wheel," was introduced to the market in Chicago. These wheels were built of side disks of steel, reinforced inside with structural shapes; the various members of the wheel being riveted together. They were used on trucks built by the Reliance, Commerce, Rapid, Plymouth, Grabowsky and Packard companies, of which all but the latter have discontinued manufacturing, and the Packard company only used a limited number. The Rapid company is said to have continued their use the longest, covering a period of about 2 years. The severe strains and shocks due to irregular road surfaces are reported to have loosened the rivets holding the various members together, and the wheels were not found to be permanently satisfactory. It is hoped that some member of the society present may have had personal experience with this type of wheel and can give us information regarding its value.

In 1908 the Morgan truck of 5-tons capacity was brought out with a disk type of cast steel wheel which proved unsatisfactory and was superseded in 1910 by a cast steel wheel with spokes of the general design with which we are familiar.

In 1909 the White company introduced steel wheels on the larger sizes of their commercial vehicles. It is understood that modification of the design of these wheels was necessary to eliminate breaking of the spokes near their point of union with the felloe, and their present design seems comparatively free from breakage. The A. O. Smith company on their heavy gas trucks have used cast steel wheels since 1911. The same is true of the Locomobile company on their well-known trucks.

From time to time trucks have been imported from abroad equipped with steel wheels, notably the Orion, Bussing, Gaggenau, etc. However, the best known European trucks coming into this country are equipped with wood wheels, notably the DeDion and Saurer. I wish to acknowledge my indebtedness to Mr. Charles E. Stone, member of this society, for his assistance in compiling the above facts.

Current Practice

It will be noted that comparatively few well-known truck builders in this country are at present using metal wheels and those who are using them have not previously used wooden wheels.

There is one notable exception, however, the Pierce-Arrow Motor Car Co., on some of whose trucks I have recently seen cast steel wheels, although since the introduction of the Pierce 5-ton truck on the market wooden wheels have been standard. It is hoped the engineers of that company will give us the benefit of their experience and their reasons for making this change.

The majority of motor truck manufacturers, including those whose product dates back to the beginning of the motor truck industry in this country, have used wooden wheels consistently, improving their design from time to time, but not abandoning a material for wheel construction which has on the whole proved entirely satisfactory.

Through the courtesy of Mr. George R. Wadsworth, member of this society, I have been furnished with reports on the mileage and condition of the wood wheels on a large group of gas trucks of 3-, 4- and 5-ton capacity, which show that in some cases the mileage covered approaches closely to 70,000. On the assumption that the tire mileage secured on these trucks is 10,000 miles per tire, this would mean that some of the wheels have been subjected to six tire changes. The report states, regarding these wheels, that "they were all in first-class condition and not a moment's inconvenience or delay has been caused by them and there is not the slightest indication of trouble in the near future." These wheels, it is scarcely necessary to say, are of modern design, are accurately constructed of suitable material, and are carefully inspected for conformation to the accepted S. A. E. motor truck wheels standards. The contention that wood wheels get out of round and present difficulties in tire application does not seem to be substantiated in this case.

As pointed out in papers on wood wheels, presented by Mr. Bert Morley and Mr. C. B. Hayes at the January, 1912, meeting of this society, there is no question as to the adequacy of the supply of wood for wheel manufacture. The experience of many of our members with wood wheels on motor trucks, extending over periods of years, indicates that the truck manufacturers in this country are not being forced by necessity to adopt metal wheels, so that if the truck manufacturer who has been using wood wheels satisfactorily for many years is to be influenced to adopt a metal wheel, it is essential that he should be shown that some practical advantage would be gained by the change.

When this society visited our British fellow engineers, several members of the American party made inquiries regarding the service rendered by metal wheels, in both England and France, and the results of the investigation were set forth in a short report which I made to the society at the January, 1912, meeting. Briefly, it was found that cast steel wheels were being used in England in a variety of forms. Also that structural steel wheels were preferred by some. Further, that the consideration of wood wheels had not been abandoned, even by those using steel wheels as a standard, and that some truck manufacturers preferred wood to metal, and used the former as standard. In France the wood wheel appeared to be the standard to the practical exclusion of metal wheels.

More recently Mr. L. C. Freeman, a member of this society, submitted a paper on "Tendency of Foreign Motor Truck Design" at the January, 1913, meeting in which he made the following statement: "While cast steel wheels seem to give very good results under certain conditions, they do not appear to be a universal panacea for all wheel troubles. One user who has operated a great many trucks of many different makes said that cast steel wheels were all right until the tires wore thin. In this statement I think there is food for a great deal of thought. A built-up wheel of structural steel was giving him excellent service and almost no trouble." Doubtless some of our British fellow engineers present at this meeting can supply us with up-to-date information on the status of the metal and wood wheel in Great Britain.

Claims for the Metal Wheels

At the present time there is undoubtedly a general effort being made by manufacturers of parts for motor trucks to add metal wheels to their product; and with the exception of one manufacturer, who proposes to build wheels of malleable iron, all of them are building their wheels of cast steel.

What, then, are the specific advantages offered by metal wheels which should influence a motor truck designer to specify metal construction rather than wood? The advantage must be such that it can be proved to the purchaser of the truck that he will secure an actual financial gain by the change which the engineer proposes, because to the purchaser the prime questions are the expense of operating and maintaining the truck over a period of years and the earnings or savings which the vehicle will effect. Theoretical considerations, unless borne out and proved in practice, are unavailing. Practical service conditions count with the hard-headed business man—not laboratory or experimental tests and calculations.

First, it is claimed by one of our members, who is chief engineer of a company about to place cast steel wheels on the market, that: "It is now conclusively proven that there is a distinct saving in tires on steel wheels. Some of the largest tire manufacturers guarantee as much as 30 to 40 per cent. longer life on steel than wood." Inquiry made of the leading tire manufacturing companies, verbally or by letter, has failed to verify that statement. The opinion of several tire company officials seems to be personally in favor of metal wheels for the one reason that they are likely to be made more accurately to size, but the tire companies positively decline to guarantee an added mile or to even express the opinion that added mileage can be expected.

As to the question of accuracy of workmanship, it is entirely feasible for the wood wheel manufacturers, under the present S. A. E. standards, equipping the wheels with S. A. E. bands, to work within the necessary tolerances and provide wheels which will have the accuracy required. Accuracy in workmanship is a question of care in construction and careful inspection and the manufacturer who insists upon accurate wood wheels conforming to S. A. E. standards has no trouble in securing them.

Another claim made for metal wheels is that their strength is greater than wood wheels. Assuming the cast steel wheels to be free from defects, and to have the chemical and physical characteristics recommended by the Iron and Steel Division, these wheels certainly develop marvelous resistance to shocks. I witnessed a test of such a wheel recently which was subjected to the impact of a weight swung as a pendulum against the side of the felloe and the wheel was deformed beyond the semblance of a wheel and even then did not show any fracture. At the same time, as has been pointed out by the Iron and Steel Division, steel castings can not be inspected against blow holes, and had the wheel in question contained some concealed defect, failure in testing would probably have resulted. The difficulty in securing uniform steel castings free from defects and conforming to the S. A. E. standards is generally conceded and several of the foundries making cast steel wheels in this country, at the present time, are having difficulty in making steel castings of other motor truck parts which will pass the inspection of some of their customers. As to the strength of well constructed and properly designed wood wheels, the front wheel of a truck manufactured by one of my clients came in contact recently with a road obstruction with such impact that the strain broke the steering gear, but the wheel was uninjured, and on another truck a rear wheel was subjected to such an impact that the axle spindle was bent without injury to the wheel. Therefore, on the question of strength, that of the high-grade wood wheel is entirely adequate for commercial purposes.

The contention is also made that the metal wheel will dissipate heat more effectively than the wood wheel. There has come under my observation no case in which a truck tire on a modern motor truck has been injured by lack of heat radiation under service conditions. I assume that the heat developed in a solid rubber tire is due to the deformation of the rubber and this is greatest near the surface of the rubber which comes in contact with the ground. This surface is in contact with the air and I should expect that the heat would be radiated through the air more easily than transmitted through the base of the tire to the wheel and hence radiated by the wheel, felloe, and spokes.

Cost and Weight

The fourth point in considering the relative merits of wood and metal wheels is the comparative cost and weight. From information received from one of my clients regarding wood wheels being regularly manufactured and used on this company's trucks, and from information received from the chief engineer of one of the companies which is bringing out cast steel wheels, the following comparison of weight and cost has been made:

Set of wheels for 3-ton truck to take 36-inch by 5-inch tires, front; and 40-inch by 4-inch dual tires, rear; wood wheels equipped with S. A. E. band and Timken hubs and flanges—steel wheels having band and hubs integral—

	Wood	Steel	Increase of Steel over Wood
Weight			
Front	122 lb. each	151 lb.	12.4%
Rear	212 lb. each	373 lb.	76.0%
Set	668 lb.	1048 lb.	57.0%—380 lb.
Cost			
Front	each $20.00	$26.80	34.0%
Rear	each 30.00	52.10	74.0%
Set	each 100.00	157.80	57.8%—$57.80

Information obtained from a European manufacturer of cast steel wheels indicates that their weight is substantially the same as American cast steel wheels, but the price is 25 to 50 per cent. higher, thereby placing the steel wheel at a still further disadvantage as far as cost is concerned. Consequently, it would appear that the cast steel wheels are both costlier and heavier than the wood wheels. The burden of proof seems to rest with the metal wheel manufacturer, that they have an economic advantage over the wood wheels, resulting in a financial saving to the owner of the truck equipped with metal wheels.

Drop Forgings

There is one type of metal wheel which might overcome the disadvantage, real or fancied, of the wood wheel, and which would at the same time eliminate the element of risk always existent in a casting, and also the criticism of the built-up structural steel wheel, the loosening rivets. This is the drop forged wheel. Drop forgings of high-grade steel, which after suitable heat treatments, develop extraordinary physical characteristics, would, in my opinion, be an ideal construction, unless their first cost proved prohibitive. I hope we may hear something from the drop forgings experts among our membership in regard to the feasibility of such a construction for motor truck wheels.

As stated at the outset of this paper, its purpose is to stimulate discussion and secure additional data, by which the motor truck designer may be benefited and assisted in his work. I trust it may accomplish its purpose.

Letters Begin Discussion

At the conclusion of this paper several letters from engineers who had been invited to comment on the paper were read. Pertinent remarks on the subject were made in these letters. H. D. Church, Packard company, stated that, in his opinion, the steel wheel would not stand up under difficult service with the certainty of other types of wheels. He advanced it as his belief that a better wheel would be developed than the metal wheel now on the market, that this wheel would be of metal but that the wood wheel would be used until that time.

A. M. Robinson, Locomobile company, stated in his letter that he thought the opinion of the London bus company would be most valuable since they were the largest users of commercial cars in the world. In reply to a letter which he wrote them stating that he understood that they were using the steel wheels on more than 2,000 buses they replied that this was the truth and that they further intended putting them on all their new buses. Mr. Robinson expressed the opinion that the use of the steel wheel increased the tire mileage to a considerable extent and that the difference in resiliency between the metal and the wood wheel amounted to practically nothing.

Benjamin Jerome stated that the Couple Gear company had had success with the structural steel wheel and that there are now in use by this company's cars, wheels of his type which have been in continuous service for 7 years.

Phineas Jones, the wheel manufacturer, stated that while a wood wheel man he did a large amount of repair work on wheels of all types. He stated that in his opinion the two main faults in the wheels which found their way into the repair shop, speaking of wooden wheels, were in workmanship and design. The main fault in workmanship was that the rims were not properly shrunk on and the main fault in design was that the wheels did not have enough spokes.

H. W. Alden, of the Timken company, stated that the paper hit the nail squarely on the head. He said that in his opinion it is too early to predict the ultimate wheel but under the present conditions the wood wheel did not do well in a dry country and that in this work there were many trucks with cast iron wheels that were giving the best of satisfaction. He stated that the tubular construction was the strongest and had the best appearance, the hollow box rim being best for the S. A. E. tires. In Mr. Alden's opinion the malleable castings are cheap and the box rim is the coming practice.

Ralph L. Morgan said in his letter that welding costs ran up so high that he found it cheaper to use the cast iron wheels. The difficulties of plate cracking he said, were chiefly connected with the lighter wheels.

Mr. Powers stated that the engineer naturally and instinctively looked for a metal to use as a material in the manufacture of wheels. He further stated that our attentions should be directed towards the British experiments with these wheels as they are much more complete and conclusive than any carried on in this country. Endurance is the vital consideration and our attentions would be directed towards this. The motor truck wheel industry is new and is progressing rapidly. The first thing that had to be done was to break away from the practice of the wagon builder which was at first followed. We have an ample timber supply here for several years and when that is taken into consideration with the fact that the wood acts as an absorber of vibration, the good effects on other parts of the mechanism are apparent.

Mr. Farrel, as a manufacturer of steel castings, stated that he believed that nothing in the way of steel casting manufacture offered any easier field than did the manufacture of the steel wheel. Referring to the statement in Mr. Slade's paper in which he stated that the wheel that was tested was not noted for defects, he stated that the particular wheel had many visible as well as invisible defects. He further stated that it would be easy to manufacture steel wheels on a competitive basis if they were ordered in anything like the quantities that wood wheels are ordered.

J. E. Hale said that as a tire manufacturer he had found that many of the troubles he had found were due to the fact that the wheels are out of round. He also stated that a well-built and well designed wood wheel was a rigid proposition and did not differ much from the steel wheel in that respect. The opinion was also advanced that there were many instances where the tire makers were not holding to all the S. A. E. specifications.

Mr. Clarkson, of the I. A. E., stated that he believed the weights furnished by Mr. Slade were too high. Taking the example of the London bus company, the wheels were 487 pounds per set lighter than those Mr. Slade had specified. Forged wheels in English practice weigh 440 pounds per set for a 3-ton truck and cost about $80 more than the wood wheels. He stated that none of the wood wheels they could get would stand 60,000 miles of London road service or an equivalent of 2 years.

Mr. Courtley stated that he had had considerable experience with wheels made from electric furnace steel and that this material had given exceptional results. The absence of blowholes is a strong point.

Keeping Track of Tires for Automobiles and Trucks

(*Continued from page 1305.*)

of the customer, the time of starting and finishing work on the job, the total time spent on it and the amount due to him for this work. The materials-used card is not shown here. It is marked with the number of the job and the name of the customer, and on it every bit of material used in connection with the repair is recorded. The tri-section card, Fig. 2, consists of. a work order, a claim check and an adjuster's slip which is attached to the tire with a string, being fitted with an eyelet for this purpose, the same as the Firestone blank.

Record System for Users

The activity of tire makers, however, does not stop with the record of sales and repair work. The proof of this statement is that the B. F. Goodrich Co. has devised a users' record system to be used on trucks equipped with Goodrich tires. This record system consists of a twelve-page book, each page representing a monthly expense sheet giving an opportunity of recording every bit of the expense of operating and maintaining the truck. Reference to Fig. 5 shows the exactness used in the drafting this form, and it may well serve as a simple and fundamental blank for truck users to keep their costs on.

The basic card in the Goodrich cost system is the driver's daily report card, Fig. 6. This card, 7 by 4 3-4 inches in size, is printed on thin, tough stock and is designed to give not only the usual information presented on a driver's report, but also full particulars in regard to the tires used.

Across the top of the card are written the number of the vehicle, its make and the date. The driver signs his name and inserts the time the report was turned in or made out below the above-named items.

These essential details having been disposed of, the remainder of the card is devoted to the information pertaining to the vehicle and its operation. Tires are classified according to the wheels on which they are carried, particulars covering the right front tire being given under the caption R F, etc. Here the tire make, size, type and repairs and cost are to be inserted in each case.

Next come data covering the day's work of the car, the weather, temperature and road conditions being given first place.

Below the space for this information, the card is divided by horizontal and vertical lines into spaces for the recording of details concerning the operation of the vehicle. At the left, under "Left and Arrived" the driver notes his destination in each case giving. below "Time," the time of his arrival at, or departure from, a loading or unloading point. The mileage covered to and from each point follows, with the number of pounds of load taken from the loading point and the number of pounds unloaded at each stop. There are spaces for data covering six trips on each card.

At the bottom, a heavy, black line is printed across the card. dividing the totals of each column from the detailed information given in each column.

The bottom of the card is left for the notation of data such as the amount of current or gasoline used, the amount of oil used, the number of miles per gallon of gasoline and the speed of the vehicle in miles per hour.

The driver is instructed to report on the back of the card any irregularities in the operation of the trucks that he has noted during the day or any mechanical or other troubles he has had in making his truck operate to its greatest efficiency. Delays at unloading or loading point should be reported by the driver as well as all mechanical troubles, for the former influence the efficiency of a commercial vehicle fully as much as the latter.

To Reduce the Expense per Mile

All these systems show the endeavor of the tire makers to give their customers efficient and economic service. The idea is to reduce the expense of each user per mile, so that he can obtain a maximum of mileage from every tire used, and the consequent expense of the adjustment department is considered as indirect advertising expense. This is to be understood as follows: prompt service must necessarily satisfy the user who gets his benefit, and any man informed by his neighbor that such-an-such a tire company is very liberal about making adjustments and informing the user how to make cheap repairs himself and helping him in every way to increase the mileage received from his tires will buy from the company thus recommended to him by a responsible acquaintance. This shows the truth of the oft-quoted adage, "Nothing counts like service."

In which Letters from Readers Are Answered and Discussed

Gearbox Discussion Attracts Comment

Oil in Cylinder Due to Bad Piston Ring—High Compression Makes Motor Difficult to Crank—Ether and Kerosene Recommended for Carbon Remover

EDITOR THE AUTOMOBILE:—A gearbox in unit with the motor enables the clutch to be inclosed, giving a very neat appearance; it is easily, and therefore cheaply, manufactured. Regarding simplicity, this depends upon the design of the unit, as some cars using unit power plants are readily accessible, while others are anything but accessible. Regarding flexibility, this type of construction can be hung so as to be undisturbed or thrown out of line.

The amidship position is very good for heavier and higher-powered cars, when used without a sub-frame. However, the manufacturing expense is greater, and the extra universal joints, while no doubt in many cases trouble-proof, require lubrication from time to time. This construction insures a good distribution of the weight on the frame.

The rear axle location is one that requires much more thought and study than the average designer who has attempted this design has given it. The drawback is not the additional unsprung weight, but the absolute necessity of swinging the propeller tube and gearshift levers from the same point. If this is not followed out, one of the most simple laws of mathematics is not taken into consideration and undue, and to say the least, unnecessary, wear is imposed upon the transmission gears. The fact that practically all of the manufacturers of all rear axle gearboxes, as well as the manufacturers of cars having rear axle gearboxes, have found it necessary to make changes from time to time and to add gear locks and to change the location of the gearshift lever goes to show that they have been having more or less trouble. Then, again, on account of the fact that the distance between gearbox and gearshift lever calls for long shifting rods and connections, there is bound to be play sooner or later in these linkages, which means that when the gearshift lever is in its proper place the shifted gear is not. In other words, the two foregoing statements prove that the gears are not having a fair show as they are transmitting power when only partly in mesh.

It is granted that by placing a universal joint between the differential and rear axle gearbox these disadvantages can probably be overcome; but why not use either the unit or amidship construction and thus do away with this unnecessary wear and tear on the gearbox gears, one of the most delicate parts of the modern motor cars?

New York City. M. H. POTTER.

¶*In answering this question car owners are directed to the fact that one of the leading arguments advanced against rear axle location is that of increased axle weight and consequent tire damage. Definite information on this line would be in order.*

¶*Those not in favor of the amidship location have urged against it lack of accessibility.*

¶*The gearbox as a unit with the motor has been criticised in that it is not suitable for a heavyweight car because of the fact that too much weight is placed in front.*

Oil Leaks Past Piston Rings

Editor THE AUTOMOBILE:—I am having some trouble with one cylinder in my model 10 Buick. Starting out with clean spark-plugs I can run for 15 to 20 miles without a skip. then the plug in this particular cylinder begins to miss fire and the engine skips badly. This particular plug will be covered with soot and by cleaning it will run about the same distance again when the same trouble begins. I have ground the valves and compression is as good as in the other cylinders. I have used Rajah, Champion and have now put in a new Wizard plug with the same result. The plugs in the other cylinders run for a month without cleaning. Do you think this trouble is due to poor piston rings, which let the oil suck up into the combustion chamber? Would new rings remedy this trouble?

Slatersville, R. I. E. O. C.

—Your diagnosis of your trouble is no doubt the correct one. It might be though that, instead of your rings being faulty in that particular cylinder, the joints have lined themselves up and allow the oil to pass through the channel thus provided. In either case you will have to take down the motor and if you are careful in taking it down not to change the position of the ring, you will be able to ascertain to what the trouble is due.

Has Hard Time Starting Car

Editor THE AUTOMOBILE:—I have a Lion car 1911 model, 40 horsepower. It was overhauled this spring, all looked over and the old wires taken off and new wires put on, as I was bothered some with short circuits. The engine was in good condition and I was not obliged to take it down at all. It has good compression and it would be impossible to spin it when cranking with the coil. The magneto has been looked over and put in first-class condition and the car is running well. It will take lots of spark before it will knock, but a man would have to be a horse to crank it to make it fire and the hotter the engine the harder it starts. I prime it every time I undertake to start it. It cranks on batteries and my batteries are good; not under 20 amperes. When I first got the car it would crank on batteries that tested 5. It will go every time as soon as it is primed. Very often if I am on a grade and I get tired of cranking I let it run down the grade with my clutch out when under fairly good headway. It will start on either magneto or batteries. I have a new Stromberg carbureter this spring. There is no skipping or back firing. I presume you will say it is the gasoline as all trouble at the present time is laid to carbureter or gasoline, but the gasoline I am using tests 65 the same as last year. I have a tester and test it myself. Could I put a Gray & Davis starter on my engine to overcome my starter troubles?

My spark-plugs burn off clean. They do not soot. They are of a reddish color. By rubbing your finger on the sparking points they will brush off and are as bright as if sand papered.

Sanquoit, N. Y. W. H. C.

—The reason that your motor is hard to crank is naturally on account of its high compression. As this is a desirable feature in an engine, it is difficult to suggest a cure except fitting a starter. This will not make the engine easier to crank, except that you will not have to do the cranking. The Gray & Davis starter is entirely a manufacturer's proposition and cannot be fitted very well to a car that is already in use, unless you go to an extremely high expense. There are many of the electric starters, however, which can be fitted to the car after it is out of the manufacturer's hands, or if you do not desire an electric starter particularly, an acetylene starter or one of the spring type can be fitted. If your motor runs well and shows no tendency to overheat there is no use in making any changes in the motor itself.

Wants Two Sets of Dry Batteries

Editor The Automobile:—I want a diagram for connecting up dry batteries in two separate sets for a two-way switch. The wiring I want to know about is this, to wire a car without a magneto so I can have two sets of batteries, so that I can use either number one or two. C. A. L.

Thompson, Pa.

—The outfit you desire will simply consist of two sets of batteries instead of one, no duplication being necessary on the coil or timer. The two battery sets should have a single ground as shown in the wiring diagram given in Fig. 1. The other terminals of the battery sets are connected with the two-way switch. so that either one can be thrown into circuit with the primary terminal of the coil. With this method of wiring one ground connection will suffice for the whole system In Fig. 1 is shown the regular coil for two sets of batteries as put on the market by Splitdorf.

Believes Valve Stems Worn

Editor The Automobile:—In looking over L. E. Grant's troubles with a Ford T 1911 and your answer for this fault I think you have missed it. I had this trouble with a Ford myself and found the cure, or a great help, in this trouble to be had by putting in a new set of intake valves. The stems of these valves wear, and when the engine is throttled down to low speed a vacuum is formed in the manifold around these stems, causing raw or fresh air to rush into the manifold, making the mixture too weak to fire.

Poplar Bluff, Mo. T. G. Van Sant.

—On page 1178 of The Automobile for June 5 L. E. Grant speaks of having trouble with his car, in that it misses fire and jerks at low speed. As the car has been run only 2,650 miles, the possibilities are more in favor of wear on the valve seat than on the stems. Since there is certainly an air leak in the car it would be well to look at both parts of the valve.

Ether as a Carbon Remover

Editor The Automobile:—About a year ago a friend suggested as a method of removing carbon from the cylinders of an automobile, to allow the motor to suck in a mixture of ether and kerosene through the carbureter or through a petcock in the manifold just above the cabureter, Fig. 2. His plan was to introduce both liquids in a mixture of equal parts with a dash of lubricating oil. Do you think that such a combination would be effective in removing carbon? Kerosene itself should answer the purpose, but how about ether or the concoction made through the mixture? Could any harm be done by using this, say once every two weeks? My friend said that this was a secret method used by some garages which charged $25 for importing the method by which the cylinder cleaning was done. I should like to see this discussed in your columns.

New York City, N. Y. H. D. Martin.

—Ether is a very powerful solvent and no doubt would be a very active agent in ridding the cylinder of carbon deposits. Kerosene also is effective and has been used in the way you mention for some time. It seems reasonable therefore that the mixture of the two should work out very well. If any readers have experimented with it The Automobile will be very glad to learn of the result obtained in actual practice.

Touring Adirondacks and White Mountains

Editor The Automobile:—I would like to have you plan an automobile trip for me, taking in Lake George from New York City, Saratoga Springs, Lake Champlain via Burlington, Vt., to Bretton Woods, N. H., White Mountains, taking in the Adirondacks.

Baltimore, Md. J. H. W.

—You can cover the country briefly outlined in a very interesting tour which will combine mountain scenery with some very pretty stretches of undulating country. Leaving New York and following closely along the course of the Hudson River, you pass straight up Broadway to Ossining, 29 miles from Columbus Circle, New York City. Here you come to the end of the road and you turn to the right on Highland Avenue, swinging

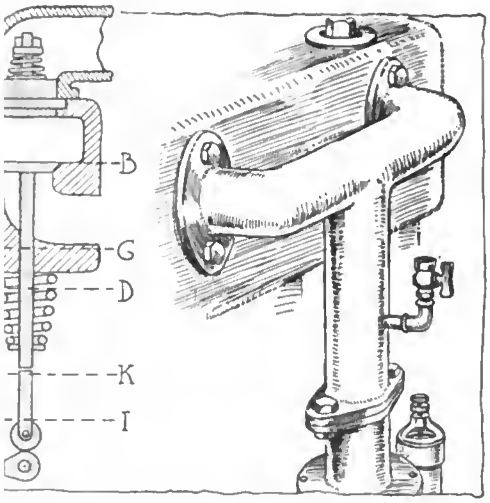
rather consume power. Consequently this one power stroke must not only be equal to the work to be done, running friction, etc., but also give the flywheel mass sufficient momentum to carry on the work during the other three strokes and the compression—something the steam egine does not have to contend with. Consequently, it is not throttled down so closely and has higher compression, in a four-cylinder more power, less power per stroke, closer throttling, greater loss than in a single cylinder, a six being a continuous power, increased throttling with greater loss than a four.

For greater elucidation of this loss, take the sketch, Fig. 2, which is an illustration of an ordinary L-head engine, also a modification of it. Take it first as an ordinary type. Say the piston stroke is from the line A B to the line C D, say 4 inches, and for easy consideration say this space is equal to 2 pints. The compression space above the line A B is equal to one-third of the 2 pints, or 2-3 pint would give 50 pounds compression pressure. Now, on the exhaust stroke the piston can shove the foul gases from the line C D up to the line A B, but above this line the expelling power of the piston ceases. Consequently, the next charge drawn in, if a full one, is handicapped with one-third its volume of foul gases to retard its ignition and combustion. If not a full charge, it is greater than one-third fouling. Also back pressure by the muffler has the same effect. When the fresh charge is drawn in these remnant foul gases are driven down on top of the piston, and at the end of the suction stroke theoretically occupy the space between the lines F A and C D, or one-quarter the space of the cylinder volume.

In W. C. Marshall's description of the O'Kill pressure indicator in The Automobile for May 29, he describes an engine of similar proportions having a compression pressure of 50 pounds per square inch, giving an explosive force of 212 pounds per square inch, yet which, when throttled down, gave only 7 pounds compression and 10 pounds explosive force. An indicator card taken from an air compressor that used water to fill the clearnace spaces shows that a charge must be compressed to about 72 per cent. of its volume to make 7 pounds compression. Two-thirds pint at 7 pounds compression would require a little over one-fourth pint addition to give it volume at atmospheric pressure. The difference or loss is, roughly speaking, with throttling, one-seventh of the compression and one-twentieth of the explosive force, but using one-eighth if the amount of explosive mixture, the mixture being handicapped with nearly three times its volume of foul gases to retard the sparking and explosion.

The slower-burning mixture giving such a reduced explosive force is what puzzles the steam user and prompts the query. Now, as a remedy for this loss, compare the second type of the sketch, which is a representation of Patent No. 1,062,494, using the same length of suction stroke, compression, etc. But instead of the piston ending its stroke at the line C D it continues on down to the line H I, twice the length of the former power stroke or with twice the crank leverage for the application of the explosive force, and also twice the expansion utilizing the heat that was formerly thrown out in the muffler. This extra expansion dispenses with the necessity of a muffler. This is one phase of the reclaiming of the loss. As the piston reaches the line H I, the slide valve begins to open. As the piston starts on its exhaust stroke it shoves the burnt gases through the now wide-open slide valve port until it almost reaches the line C D. The exhaust valve E then begins to open and the exhaust is continued through it to the end of the stroke (meanwhile the slide valve running at crank shaft speed, but 90 degrees



L-head motor—Petcock on manifold

late, has closed its port), the valve E remaining open, the piston on beginning its suction stroke draws in air through it until the piston has reached the line C D, the valve E closing. The mixture is drawn in through the inlet valve until the piston has reached the limit of its stroke, the line H I. Here the remnant foul gases occupy the same position in relation to the piston between the lines H I and J K, the slide valve again opening the piston on its return or compression stroke. Now it will be noted that the foul gases occupy the space between H I and J K, air between J K and F G, and above F G the fresh mixture, two valves at the top being closed. The piston shoves on the foul gases, these on the air, and the air on the mixture. The air, being at the slide valve, port is forced out through it as the piston comes up, the foul gases being the last forced out, thus obtaining complete scavenging. Also observe that the action forces a compact filling of the upper or explosive end of cylinder, peculiarly fitting it for a high-speed engine, fresh air occupying the space (which in the first type was filled with foul gases) on top of the piston, increasing the explosive force by greater oxidation. In a recent issue of THE AUTOMOBILE was reported a discussion by the S. A. E. in which Howard Coffin was credited with saying that "A quantity of air on top of the piston would create an explosive force the present type of engine would be unable to withstand." Here we have a simple and practical embodiment of this noted engineer's idea, but further economy by further expansion. The mixture intake stroke being 2 pints, would not go below the line F G, no loss through slide valve port, for a lighted torch held there gives no flame. Having no throttle, a light power stroke is obtained by pushing the angular end of the push rod into contact with the nose of the cam, holding the valve E open longer, taking in more air, less mixture. Now if 2 pints containing a certain number of heat units compressed to 50 pounds compression gave an explosive force of 212 pounds, why one-eighth of 2 pints of mixture having one-eighth the heat units ought to give one-eighth the explosive force under the same compression, or over 26 pounds per square inch. But the increased oxidation, as Mr. Coffin states, would give more over 30 pounds. A single cylinder engine of this type but with a leaky piston running between 300 and 400 r.p.m. drove a lathe doing work for 7 hours, using 3 pints of gasoline and 1 pint of kerosene in an engine 3 by 8 inches, no attempt being made as to economy, no regulator or governor, but the time set of the valve E and the set of the carbureter needle valve. This engine, with a flywheel of less than 100 pounds, ran at 80 r.p.m. and drove an idle lathe, and with this low compression has burnt high and low test gasoline, benzine, alcohol, kerosene, turpentine and crude oil, one after the other, with no alteration but a slight change in the set of the carbureter, needle valve, turpentine and kerosene giving highest engine speed with a certain set of the carbureter needle valve, benzine and crude oil next, etc. In over 2 years' running there was no carbon deposit. With perfect scavenging I think this upholds my contention that the loss by heat radiation is far-fetched.

Scavenging vs. Compression

An automobile equipped wtih a six-cylinder engine of this type of engine would then run as economically as a single-cylinder, but with the smoothness of constant torque, and could crawl through the congested city streets at a snail's pace on high gear or suddenly "hit her up" with anything that "came down the pike." This type of engine with added appliances of small construction cost would enable each piston on its every upstroke to be an air compressor with a variable air release at end of stroke requiring no extra valves, a four having four compression strokes and a six having six at every revolution of the crankshaft, making a braking force that would allow a car to float down a gentle decline or come to a stop on the steepest hill without recourse to brakes.

It will be seen that this type of engine possesses superior advantages, its perfect scavenging admits of lower compression, the present type with its retention of foul gases and also throttling requiring high c

temperatures, respec-
nal pressures, respec-

suppose that a 34 by
er square inch, is run
ns on a day when the
ees Fahrenheit. The

temperature will increase in a test of this kind about 35 degrees, this being determined by experiment.

"Applying the above formula T' equals 67 degrees, P equals 72 pounds per square inch and T equals 32 degrees. Therefore, the final pressure or P' equals

$$\frac{(67 \text{ plus } 460) \times (72 \text{ plus } 14.7)}{32 \text{ plus } 460} = 14.7 = 78.1$$ pounds per square inch.

"You will note that the increase in pressure in the tire due to the heating of the tire in this specific case is 6.1 pounds per square inch.

"Again, suppose that a 34 by 4 tire is run as above, but on a day when the thermometer is at the mean temperature, or 62 degrees Fahrenheit; then the increase in temperature of the tire would be slightly less than 35 degrees, possibly 34 degrees, this being due to the greater radiation of heat by the tire at the higher atmospheric temperature.

"Applying the above formula again, the final pressure in this case would be 77.6 pounds per square inch, an increase of 5.6 pounds, due to the heating of the air. Similarly, the pressure in the tire run as above on a day when the thermometer stands at 90 degrees Fahrenheit, would increase from 72 pounds per square inch to 77.2 pounds per square inch, an increase of 5.2 per square inch.

"This information can be more readily grasped at a glance from the following table:

Atmospheric Temp. or Initial Temp. of tire	Pressure in the tire before run	Increase in Temp. due to run	Increase in pressure due to run	Final pressure
32 degrees	72 sq. in.	35 degrees	6.1 sq. in.	78.1 sq. in.
62 degrees	72 sq. in.	34 degrees	5:6 sq. in.	77.6 sq. in.
90 degrees	72 sq. in.	33 degrees	5.2 sq. in.	77.2 sq. in.

"As a matter of fact, the increases in pressure would be very slightly less than those noted above. due to a slightly greater

Overloading Ruins Solid

Average Truck Driver Ignores Fact That M
and Speed Are the Prime Essentials of Ti

THE average truck driver does not know of the dangers due to overloading and over-speeding. A solid rubber tire seems to all intents and purposes proof against injury, which fact is one of the greatest dangers. Does he know of the wear and tear on these tires caused by overloading, hard, quick braking, over-speeding, skidding, bad roads and neglected cuts? The question of attention and repairs they should receive during use is another important point to consider.

Speed is the most important of all the deteriorating influences to which tires are subjected. It has been determined that an average of 12 miles an hour, the life of a solid tire, approximates 10,000 miles, while at an average speed of 20 miles an hour it would be a candidate for the scrap heap at the end of about 4,000 miles.

The B. F. Goodrich Company, Akron, Ohio, says that the dangerous effect of overloading cannot be ovverestimated. Tires are constructed to carry certain loads which, if exceeded, will result in premature failure of the tire unit. Rubber compressed beyond its safe limit of elasticity will break down just as any other material will do.

The Goodyear Tire & Rubber Company, Akron, Ohio, says that skidding, starting and stopping, tractive effort, are in the nature of natural causes of wear. In truth, are causes of ordinary abrasion under practically normal conditions. Habitually running in car tracks has its invariable ill result in a similar manner. For the edge of the tire, the small portion which runs on the rail is carrying the load intended for the whole tire. A further shearing effect is produced, too, that is most injurious to the tire's fastening.

An improvement has been made upon the Motz cushion tire. This tire is constructed with undercut sides which form slant-

wise bridges. These u

expansion of the tire itself caused by the greater pressures.

"The point of this whole discussion is that the increase in pressure, due to the heating of the tire, is not nearly so great as is commonly supposed, but for a given run is less on a hot day than on a cold day.

"Of course, this heating of a tire is injurious to it, but whenever the pressure in a tire is decreased, the heating of the tire is increased, rather than decreased, on account of the greater bending of the tire and consequent greater friction and generation of heat.

"From the above it should be clear that the pressure in a tire should not be decreased on a hot day as is commonly supposed, for the simple reason that it is impossible to obtain an increase in the pressure, due to the heating of the tire in service, sufficiently to in any way injure it."

The Racine Rubber Co., Racine, Wis., says that "at least 75 per cent. of the tires in use are ruined directly or indirectly through lack of proper inflation. A tire is built to the exact shape it should assume when put into service, and inflated to the proper pressure, but when this pressure is not observed the tire is constantly running under an unnatural strain, which, in a short time, causes the fabric to crack, due to the excessive flexing caused by under-inflation.

"A great many car owners do not observe proper tire pressures until after they have weakened the inner walls of the tire

through under-inflation,

in proportion to the value of the suggestion. These prizes are a standing offer, and little boxes are fastened to the walls in various parts of the factory in which to drop notes and sketches dealing with the suggestions. The boxes are visited regularly and the ideas offered are given careful consideration. Besides, the employees thus have a means of communicating any alleged wrongs direct to the heads. The scheme has worked very well, and has been the means of effecting several valuable improvements in machinery, and in the plants as a whole. For a certain attachment to one of the machines which eliminated one hand operation, one man not long ago was presented with $100 and a promotion.

The Goodyear Company maintains a fully-equipped emergency hospital off in a quiet wing of one of the buildings. This is in charge of an able physician and surgeon paid by the company, who does nothing but its work. In addition, trained nurses are employed day and night. THE AUTOMOBILE representative was given an opportunity to inspect this feature of the plant, which is a model of its kind. Kept in immaculate condition, this hospital has the most modern of surgical equipment. It includes an operating room where the most difficult of emergency operations may be performed.

In addition, there is a sick ward containing half a dozen beds where injured men may be quartered for any necessary length of time under the best of care. There is also a similarly-conducted women's ward. Although accidents are carefully guarded against, nevertheless, they will sometimes occur, and this one feature of the welfare work has many times helped sick or injured men to quick recovery who at their homes would not get proper care. The company assumes no responsibility for the consequences of injuries not immediately reported at the hospital.

Directions Well Posted

Everywhere throughout the factory buildings, signs and arrows are posted directing to the hospital by the shortest route, so that in case of an accident, no time will be lost in reaching the doctor and his assistants. These signs are simply small metal affairs with the arrow and the words "to hospital" on them. They remind one of the signs along the highway directing to the different towns. Each corridor, hallway and turn is thus placarded every few feet.

The restaurant or lunch room is also an important feature. It is located on the top floor at the end of one of the main buildings, and serves four meals each day. Breakfast is provided from 5.30 to 7 a. m., noon lunch from 11.30 to 12.30, supper from 5 to 6 p. m., and midnight lunch for the night force from 11.30 to 12 p. m. The lunch room is not operated for profit, but aims to work on a cost basis, so that a workman can get a very good meal for an exceedingly small outlay.

It is, of course, next to impossible to fix up the prices so that

Type of cottage which the Goodyear company is building to furnish its workmen and their families 'estaurant will run exactly even, so that whenever the finan-report issued every four months, shows a profit or a deficit, prices are reduced or increased slightly to overcome the :rence. For the four months ending March 1, a deficit of 39.39 was shown, and the price was therefore slightly raised :over the loss. For the previous quarter year a profit had ı shown which had resulted in perhaps too great a reduction. ast April another idea which had been contemplated for e time by the Goodyear Company was matured. "Hotel ›dyear" was opened to accommodate new employees of the ıpany, affording them temporary quarters until they could find :manent residences in the city. A building adjoining the plant ; purchased and the upper floor fitted up for living purposes. 'artitions were erected dividing the space off into four large ms and some smaller ones. Three of these rooms are used sleeping rooms, while the fourth is set aside for a reading m, where magazines and newspapers are furnished. Here the n may spend their spare time if they wish. Two of the eping rooms will hold fourteen men each while the third has ›m for twelve, so that the "hotel" offers accommodations for ·ty men. There are shower baths, and each man is provided :h a locker. Beds, bed clothing and the like are furnished by : company. The sleeping rooms are kept quiet at all times, r the accommodation of both night and day men.

As the hotel is intended primarily to afford a cheap and com-rtable living place for newcomers, they are expected to find a rmanent location in the city as soon as possible so as to make om for later arrivals. To aid them, the employment office eps a record of all rooming houses, so that it should not take man over a week to become located. With this end in view, nominal sliding scale of prices for lodging at the hotel has :en fixed. Thus, 15 cents a day is charged for the first two eeks, 20 cents for the next week and 25 cents thereafter.

The hotel so far has proven an immense success, and the men ıve eagerly taken to the idea. The accommodations afforded :e really better and cheaper than they could find elsewhere, and is sometimes a hard matter to get the men to move after ıey have been there for some time, in order to make room for thers.

Another plan for the benefit of the Goodyear employees must ot be overlooked here. This is a scheme for allowing the ›orkers to purchase attractive homes from the company. A ırge tract of land across the street from the factory and in a eautiful hilly section with a commanding view of the town has ›een purchased by the Goodyear interests and is now being di-·ided off into streets. Water mains and sewers are being put n. In fact, all the streets in the section where the first hundred ıouses are to be built have been graded and are ready for build-ng operations.

The company is to divide this property off into lots, and on :ach an attractive house is to be built. Each will be individual

thus making for simple production. The horsepower is given at 16 on the block at a speed of 1,600 revolutions per minute. The crankshaft is carried on two main bearings, the rear bearing being carried in an end plate which covers a hole through which the crankshaft may be removed. Although the crankcase is all one piece, it is easy to inspect the connecting-rod bearings through a long plate bolted to the bottom of the crankcase.

The manifold construction is also a simplification of general motor practice. Referring to the view of the engine herewith, it will be seen that all manifolds are cast integral with the cylinder casting. The inlet manifold connection is below the flanged exhaust duct on the right side. Still lower is a cover plate, the removal of which gives access to the valve mechanism. The location of the inlet manifold below the exhaust makes it possible for the gas to be heated by the exhaust before it enters the cylinders. The valves of the regular poppet type, have a diameter of 1 5-16 inch and their lift is 5-16 inch.

On the right side are also the Mayer carbureter and the Bosch magneto, the former being at the back while the magneto sits forward, so that there is no congested condition of these two necessaries. Timing gears are located forward and enclosed in the usual way. As an aid to silence they are helically cut instead of being of the straight spur type. From the magneto shaft, the fan is driven through pulleys and belt. Adjustment of the belt

›n is accomplished through a take-up bracket and integral the top plate.

logical advantages over differential gearing are claimed
evice. Since there is no possibility of one wheel alone
while in a rut or on soft ground, the elimination of
e slippage is a factor in tire economy. No lubricant is
within the clutch mechanism, as any grease or oil
nd to cause sticking of the rollers, preventing their
tion in the runways. There is no wear between the
arts as there is no sliding or rolling contact. Stalling
otor, skidding when brakes are suddenly applied, and
ng are also reduced to the minimum necessarily. It is
ned that an axle embodying the releasing clutch costs
nanufacture than does a rear unit equipped with the
nal form of differential.

ycle-Truck the Newest in the Commerc

Harley-Davidson Company Announces Two-Speed Vehic with a Nominally-Rated Carrying Capacity of 600 Poun

ЭR several years the Harley-Davidson Motor Co., Milwaukee, Wis., manufacturer of motorcycles, has been experimenting with various types of light delivery vehicles, the result of this work being the introduction of a light wheeled delivery truck driven by a two-cylinder motor. ruck is designed to carry 600 pounds in addition to the , and has an overload capacity of again as much. The is standard, 56 inches, and the wheelbase is 76 inches. The ird body is 2 feet 10 inches wide, 3 feet 6 inches long and 4 inches high, with the doors opening in front. This truck es easily in congested traffic and under all kinds of road ions. It is equipped with the Harley-Davidson two-speed which gives a ratio of 5 to 1 on high speeds and a ratio of 1 on low speeds.

h a maximum load the truck can be started easily in mud ow and on heavy grades. In light fluffy snow less than 6 deep it was possible to attain speeds of considerably better 5 miles an hour with a maximum load. The slush and mud t spring and of a year ago did not interfere with its use day.

value of this feature cannot be overstated: In many it is against the law for a chauffeur to leave his motor ig when he leaves the car. To expect the driver of a truck ık his automobile 150 or more times a day—depending upon imber of deliveries made—is, of course, out of the ques- As a result, in motor truck delivery it is necessary to have en where many stops are made.

er transmission is through a Harley clutch, the gears being in mesh though they are not running except when low being used. The gear-shifting mechanism is directly in of the saddle and above the clutch lever, as shown in the ition.

braking is done with either pedal. In addition to the ad- e incorporated in this feature, the driver has an additional edal easily convenient to his right foot.

brake can be locked in any position, a necessary conven- hen the motorcycle truck is stopped on a hill. The brake hes in diameter with a face .875 inch wide. Well-designed mudguards protect the driver so this tr spective of weather conditions.

The chassis is constructed of pressed st under the body and side stays to the fram so that the strains of the load are evenly sis follows generally the practices of auto struction. The steering knuckles have b and bottom.

The truck is equipped with 28-inch whe forty heavy spokes and large hubs especi structed for this work.

Three-inch tires are used on all three wl gravity is obtained with the underslung cient clearance is provided for even the in Wisconsin in January and February. T the car is carried on semi-elliptic spri Hardened steel bushings and pins are use

In a test by D. C. Owen, postmaster of of 14.2 miles, 4.5 hours were required as time when deliveries were made with a hor the motorcycle truck made fifty-three sto regular parcel post man was carried on although in actual service, of course, this a not have to be carried.

The motorcycle trucks now in service h when used for long runs, they make fro gallon of gasoline. The gasoline consump tion given for the benefit of the postoffice was a trifle less than half a gallon. Fig with an oil consumption of 250 miles per g seen that the operating cost of a motorc cents a day for a 10-hour day, covering 75

treads which fit over any pneumatic
from the same material as goes into pneumatic tire treads. They are made of several layers of S
Island cotton fabric, and a compound of pure Para rubber. Th
protectors are made with either a plain or non-skid tread.

The Colorado Tire & Leather Co., Denver, Col.—The pr
tector produced by this company is of the straight-side a
clincher type, made to fit all sizes and styles of pneumatic tir
It is built of water-proof, non-hardening, non-cracking, special
tanned leather. The successive layers of non-cracking leath
are held securely together by a series of rivets, having large st
heads for contact with the road, which are riveted upon the i
side and separated from the tire by the body portion of t
protector; the number of rows of rivets are regulated by t
size of the tire, ranging from three to six rows, dependi
upon the diameter and width.

Triple Tread Mfg. Co., Chicago, Ill.—This company ma
ufactures a protector which is used for tires which have su
fered blow-outs or rim cuts. This protector when vulcaniz
to these blown-out tires renders them absolutely puncture pro
and non-skidding. The old casing is used as a foundation up
which to build, covering it entirely with tough, wear-resistir
water-proof French chrome leather. A guarantee of 3,500 mil
is given

Leather Tire Goods Co., Niagara Falls, N. Y.—This cor
pany makes the Woodworth tread, which is a steel-studd
leather covering, for use over automobile tires to protect the
from punctures, cuts, wear, or other outside injuries. The
protectors are made of two plies of chrome cow-hide leath
having between them on the middle part of the tread a reinforc
ment of tire fabric, which, being practically inelastic, preven
the treads stretching in circumference. The steel studs a
clinched entirely through this material so that they are he
very firmly in place and prevent any danger of the plies of mat
rial separating. The outer ply of leather in these treads
treated by a secret process which fills the pores with rubber-li
gums that prevent moisture and dirt from getting into the fibr
and so keep the leather soft and tough.

Among the other companies manufacturing tire protectors
various kinds are:

Goodyear Tire and Rubber Co.

the rubber is broken down sufficiently in the cracker, it is then run
another washing machine, similar to the cracker except that the
rs are grooved. The cylinders of this machine work very close to-
so that the rubber is finely ground and run into a thin and com-
ely smooth sheet. Water also flows upon the rubber during this
, which takes out anything foreign that might have slipped through
cker. This continues until the rubber is thoroughly cleaned. After
un to a certain thickness the rubber is ready for the drying room.

rious concerns since being abandoned by the carriage
iny.

ablished Portable Garage Department—The Milwaukee
gating Co., Milwaukee, Wis., manufacturing all kinds
rrugated metal goods, roofing, etc., has established a
tment for the manufacture and marketing of portable
es.

ablishes Kenosha Plant—The K. & F. Mfg. Co., or-
d recently by Chicago, Ill., and Kenosha, Wis., capital,
stablished a plant on Exchange street, Kenosha, for
nanufacture of metal and glass containers, measuring
s, caps, etc.

n Brown's $100,000 Plant—The contract for a new plant
e J. W. Brown Mfg. Co., Columbus, O., maker of auto-
e lamps, has been awarded. The plant will be erected
site recently acquired and will be 100 by 400 feet, two
s high, to cost about $100,000.

Extend Plant—Two additional stories are to be added
e one-story Denver, Col., assembling factory of the
Motor Co., Detroit, Mich. The two stories are to have
ntage of 42 feet and a depth of 77 feet. The addition is
of reinforced concrete and will cost $60,500.

TION IN HARTFORD—The Hartford Electric Storage Battery Hartford, Conn., has opened a battery station on Wells

DECREASE HARNESS IMPORT—Decreases in the imports of and saddlery into Argentina are attributed to the growing iles.

IC CHARGING STATION—The Tate Electric Co. is opening a and electrical garage in Montreal, Que. It is estimated irty cars will be housed.

BBER AGENCY TAKEN—An agency for the Gabriel Snubber has been taken in Indiana by the Cadillac Automobile Co. ich is located in Indianapolis.

K's AUTOMOBILE SERVICE—The Grand Trunk Railroad is advisability of installing automobile service between Buf- l Bridgeburg, Ont., for Sunday travel.

DETROIT DIAMOND MANAGER—L. K. Rittenhouse has been of the Detroit, Mich., branch of the Diamond Rubber Co., was former Boston, Mass., manager of that company.

ST. LOUIS—A plan to use automobile buses to develop St. lissouri, is under way, and a company to operate bus lines rthouse in St. Louis and Clayton, the county seat of St. preparing to ask the city for a franchise.

GNS—Frank E. Chapman has resigned as superintendent of repair department of the Maxwell-Newcastle Manufacturing Ind. He will be succeeded July 1 by E. A. Richmond, of ormer director of the claims office of the Flanders Corp.

FOR FIRE CHIEFS—An appropriation of $3,400 has been re- loard of Safety of Indianapolis, Ind. The money is to be mobiles for the second and third assistant fire chiefs, the d fourth assistants now being so equipped. Charles E. Coots, o longer possible for assistant chiefs to cover the city with cles.

NS FROM FIAT—Richard D. Willard, secretary of the Fiat , Poughkeepsie, N. Y., and manager of the New York mpany, has resigned, having disposed of all his interests Willard has not yet announced his new connection and it ll take a brief vacation trip before taking up with any of t have been made to him.

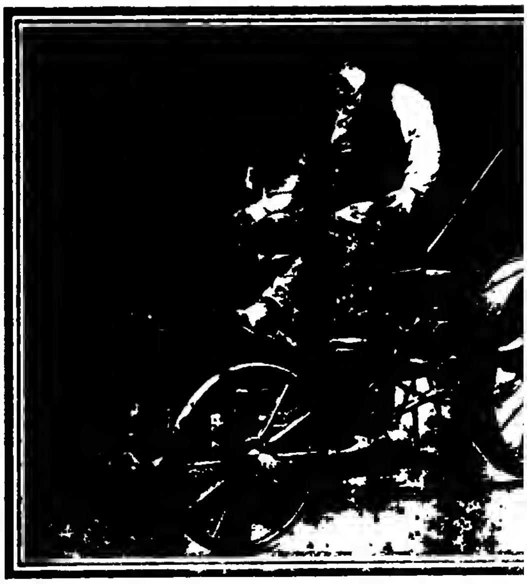
BILES AT SCHOOL—Two automobiles, small but in every machines and capable of making 25 miles an hour, are n in the machinery shop of the Polytechnic High School Cal. Practically every part of the cars, from the engines ies to the chassis and wheels, were built by young students the practical application of their work in the machinery

ETTYSBURG CELEBRATION—The Federal Government, in ns for the semi-centennial celebration of the Battle of held at Gettysburg, July 1 to 4, has engaged fifteen eks. In the transportation of camp supplies, commissary ggage of the veterans the Autocars will be extensively ntervals when not engaged in such duties will be employed rposes over the battlefield.

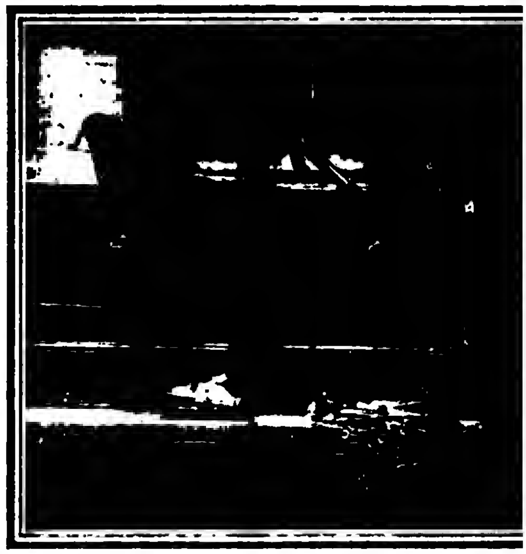
LIC LIFTING JACK—Capt. J. Lee Knight, of Fond du Lac, a new type of water pump or hydraulic lift, using the rinciple instead of suction, is forming a company to ulic devices of all kinds. Capt. Knight has designed a lifting jack especially adapted for motoring purposes rned out in large numbers. The jack has two lifting pis- sed either in horizontal or vertical positions.

Y BUILDING—To keep abreast with his fast-growing auto s, Fred Campbell has leased the five-story building at St. Louis, Mo., for five years and as soon as alterations ill move his stock into the new quarters. Both wholesale will be taken care of at the new location, which is on n automobile route, but will be principally devoted to , the retail trade being handled, where possible, at the t King's Highway and Delmar Boulevard.

TS GOOD BUSINESS—Jesse Froehlich, vice-president of the mobile Co., New York City, reports that its business for has far exceeded the greatest expectation. Mr. Froeh- is company expects to offer the greatest sensation yet fered on high-grade runabouts in the near future, for rrangement with the manufacturers, it has agreed not ame. Work will be started soon on two additional t building at 56th street and broadway.



Farm tractor built at Hartford, Conn. This m with a two-cycle Motorette engine, the crankshaf which are equipped with pulleys for transmission



New Lozier construction. Several compartments con are designed to carry all tools

ɔols That Facilitate Repairs

ıir today is not the difficult and . was only a few years ago. And in a large measure to progress in a great deal of the credit must be levelopment of the tools which fa- changes.

and other handy repair tools taken the above illustration. All are pro- ıstment whereby any size of tire can

ıis tool, shown at A, consists essen- ;ed parts so arranged that great force the side of the tire by simply hook- er the nearest spoke as shown. It is removal or replacement of rims or ıe applied at either side.

another simple lever formed with a can be used as an extension handle required. The whole folds compactly ches and weighs 5 pounds. The price the makers, the Rudolf Tire Co., Pitts-

The Shawyer Co., Springfield, O., have ŧ will fit any size of tire from 3 inches ȝ used for relieving lock rings as well as th sides of a clincher tire. This is il- hich it will be seen to consist of two ıws with an adjustable link surrounding he middle, to which a lever is hinged in ȝ inner end bears powerfully on one of hem both together. As shown, the tool the rim, that is, between the spokes, but rings or easing both sides of a clincher e it is applied outside, the curved portion ding the tire. This tool weighs 4 pounds

—When putting on a clincher tire much ɛperienced in preventing one part creeping while levering in at another point. To ɾ independent of extra help in this con- ɩool shown at C will be found useful. The the method of application. The nose is rim, the curved handle meanwhile serving which it is simply turned down and bears ɩtually holding the bead at that point. It is equally applicable to wood or wire-spoked wheels. Manufactured by the Michigan Motor Specialties Co., Detroit, Mich., and listed at 25 cents each.

"2d Man" Tire Tool—Another handy little tool for th same purpose is shown at E. This consists of a steel hoo to which is attached a leather strap for passing around th tire. After inserting the hook between the tire and rim th free end of the strap is pulled tight and buttoned to th tool. These are manufactured by B. Morgan, Newport, R. I and sell at 50 cents.

Q. D. Rim Remover.—A remarkably simple tool to facilitate the removal of quick detachable rims is shown at D This is stamped out of sheet steel and in use the bod portion is hooked over the outer edge of the tire rim wit the nose occupying a position between the ends of the locking ring. Then by turning the screw the rim is easily move over and the locking ring exposed for removal.

It will be noticed that one of the conditions necessitate by this tool is that the ends of the locking ring be far enoug apart to allow the entry of the hook, and the maker advise that if this space is insufficient the ends should be filed t suit.

The manufacturer is William L. Tobey, East Boston, Mass Nickel-plated and casehardened this tool sells for 65 cents

L. & M. Tire Loosener—The tool shown at F, manufactured by the Adam A. Long Machine Works, Rocheste N. Y., operates on the rack and pinion principle, producin a parallel motion of the jaws by turning the handle. By th nature of its construction this tool is applicable to a wid range of tire sizes providing the same leverage in all case As shown, the tool is in use as a shoe loosener on a clinche rim but it can also be used for removing the tire from Q. D. rim. In this case the movable jaw is passed righ over the fixed one, a semi-revolution of the removable handl being required. It is made of malleable iron and steel i two sizes, No. 1, for all tires up to 5 inches and No. 2 fo 5.5 to 6 inches.

The handle is detachable so that the tool occupies a sma space. The prices are $2 and $2.50.

Morris Tire Tool—The principal feature of this tire remover shown at G is the means for rapidly adjusting t any size of tire without removing any parts or turning screw The lever is divided at the fulcrum and the fixed portion i notched to receive the hinge pin. This tool sells at $1.50 an is the product of the Wm. E. Pratt Mfg. Co., Chicago, Il

rlocks—A device for increasing tire mileage and re- the danger of blow-outs is being marketed by the Double Co., Auburn, Ind., under the name Interlocks.

tire-saver differs from general practice in inner pro- in that it is not a shoe but a complete inner tire, which s a position between the outer casing and the inner tube, hening the casing and protecting the tube from punctures. mufacturer claims that their use does not affect the resil- o any appreciable extent.

ver Automatic Oiler—An auxiliary oiler for attach- o Model T Ford motors has been brought out by the A. C. Co., Providence, R. I. The views in Fig. 5 show the and the method of applying it to the base of the crankcase. be seen to consist of a flanged chamber A, drilled to fit the existing bottom plate B of the crankcase, and a pipe P ng from it to the lowest point of the flywheel casing. way a complete circulatory system is obtained, the oil aised from its lowest point by the flywheel.

pplying the device it is only necessary to remove the plug base of the flywheel casing and drill a hole through the ise cover between the second and third connecting rod dips insertion of the short standpipe S.

ltale T is fitted to the side reading from 3 to 8 quarts. rmal filling is 7 quarts and this is poured into the breather the ordinary way of oiling. In passing from the flywheel is conveyed through a copper pipe, not shown, to the gear before flowing into the crankcase. The oiler cham- neasures 12 inches long by 5 inches deep and is an alumi- sting. Clean-out plugs C are provided at the base and the the connecting pipe. The device can be put on a car in · and is listed at $12.

h's Interchangeable Tool—This tool, shown in Fig. sts of a set of pliers, pincers and shear tool jaws with a common to all. It is supplied with six heads for various s. In the set for automobilists the jaws include a com- i plier with cutter, a close cutting nipper for cutting light l, a pincer head for heavy work, a leather punch, tinner's and Weed chain plier.

llustration shows a handy roll of strong duck with sep- ockets which forms a convenient way of carrying this re tool kit. It is also supplied in a compact wood case, e for either being $3.

taching the various tool heads it is only necessary to a thumbnut on the center bolt. The head shown fitted andle at A is that for use in connection with Weed chains. esigned to open the links easily and at just the correct ·. The maker is the Currier-Koeth Mfg. Co., Couders- 1.

Hoover Auxiliary Spring, shown in Fig 8, is remark- iong shock absorbers for its extreme simplicity. It will that it consists of what is in reality a miniature spring l on the same lines as the conventional main spring and directly underneath it. The illustration shows the prin- action of this device. When the car is carrying a light is running over smooth road and the main spring is con- ly at its greatest curvature as at A, the tips of the auxil- ring are free. The car is therefore riding on the main alone. But as soon as an unusual strain is encountered main spring is flexed the auxiliary comes into action as at B, supplying the desired additional support.

maker is the Hoover Spring Co., San Francisco, Cal., device is supplied in five widths, 1.5, 1.75, 2, 2.25 and 2.5 espectively, at prices for each set of four from $14 for ll size to $18 for the largest.

Manufacturers of 1913 Models

Don't omit a SPARKS-WITHINGTON Fan from your 1913 specifications. Our One-Piece blade, ball-bearing, radiator fan assemblies cool the motors of more high-class cars than any other fan on the market. There's a reason. SPARKS-WITHINGTON Fans deliver the greatest volume of air with the least H. P. consumption of any fan obtainable. Furthermore, their one-piece construction is positive insurance against blades which loosen, become detached and fly off. Undoubtedly one of our ten standard models is just what you have been looking for. Catalogue and detailed blue-prints on request. Get in touch with us.

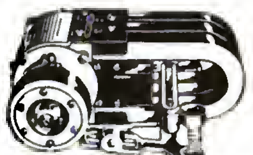
IMPROVE THE APPEARANCE AND EFFICIENCY OF YOUR CAR BY INSTALLING THE

K-W Electric Headlight Outfit, $40

Complete Outfit, Generator, Head Lamps, Switch, Wire and Bulbs



EASY TO INSTALL ON ANY CAR having exposed flywheel or other place to drive the Generator.

LIGHT WEIGHT Generator weighs but 18 lbs. Compare it to the heavy, complicated and costly charging outfits. If you have the Electric Head Lamps, get the K-W Electric Generator, only $25. Can be used for Ignition in connection with Timer and Spark Coil.

HANDSOME MADE-FOR-THE-PURPOSE HEAD LAMPS. The Reflectors are set in the door against a felt ring to keep out dust and moisture. They are made of correctly formed brass heavily silvered and highly polished on the reflecting surface. Lamps alone $15 and $17. No extra charge for black finish.

K-W Ford Electric Headlight Outfit, $15

For Ford Cars With Flywheel Magneto

The successor to the gas tank. The most successful electric headlight outfit for Ford Cars, because it is especially designed and engineered to work in connection with the Ford Flywheel Magneto.

Cable-Struc

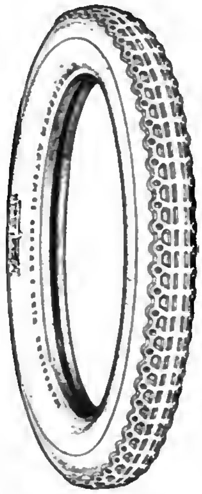
Tires—& W

Dealers, your business success d your service to customers, doesn't it chandise you sell must give satisfa lose trade. That law holds true in al can't afford to sell any tire but Mansfield Cable-Structur is that tir the reasons WHY it is best and SHOULD SELL CABLE-STRUCT

Unlimited in Quality

First we build unlimited quality into Cable-Structur tires. We use only the highest quality materials. Only fabric that will test at least 325 pounds per square inch, and this fabric is so woven as to permit of complete impregnation of new rubber.

And we use only the finest new rubber. This is given greatest endurance by our secret formula.



Unbreakable Base

24 endless, no-stretch steel wires, 12 on each side, are vulcanized into the semi-hard rubber beads. This gives the most logical tire base—and absolute safety.

These 24 wires give a tensile strength of 16,800 pounds.

Saving Rim Ruin

This basal construction makes a hooked base unnecessary. So the flange hooks are turned from the tire. Therefore no rim-damage is done if the tire is run soft, from any cause.

More Carrying Power

This compact Cable-Structur base gives greater air space. That gives the tire greater carrying power, that saves blowouts and their costs.

Careful Hand Building

Our careful hand building insures utmost exactness. Every inch of fabric is applied with unvarying precision. That means uniform strength.

Built Slowly

Cable-Structur tires are built very slowly. It costs

At Camp Week-End

Third of the Hupmobile Outdoor series now appearing in the national advertising—and giving Hupmobile dealers a new sales lead.

A huge sales organization with one definite aim

Our aim is to make every Hupmobile dealer an integral part of a huge sales organization—not let him remain merely an automobile dealer.

We believe thoroughly in co-operation.

We want the co-operation of every Hupmobile dealer, naturally.

But, what is vastly more important to the dealer himself, we want him to accept and avail himself of our co-operation in his own territory.

We want the Hupmobile dealer to be as close to the factory as those members of the sales department who are inside the factory.

He should be, in fact, a member of the Hupmobile sales organization—working along definite lines, with a very definite purpose to accomplish.

And we can materially aid and assist every Hupmobile dealer who imbues himself with this spirit, as the majority of our dealers have learned.

A car with a reputation, and the quality to maintain its good name; a widespread and continuous advertising campaign; a home journal for Hupmobile dealers and no one else; sales suggestions of real and definite value.

These are the Hupmobile dealer's privileges and prerogatives—the things that link him closely and securely to the factory.

These are advantages beyond the power of every motor car manufacturer to offer.

R COMPANY, 1252 Milwaukee Ave., Detroit, Mich.

by HUPP MOTOR CAR CO., Ltd. Factory, Windsor, Ontario

The BRAENDER TIRES are the only tires that went the entire distance in the g Decoration Day race without a change. These were STOCK TIRES—the same kind that *you can* and *do* buy through any dealer selling BRAENDER TIRES.

This is the most wonderful record ever made by tires of any make.

The BRAENDER TIRES after the race were capable of several hundred miles c tional service. The only sign of wear was on the right front—a cut from running over part dropped from another car.

DEALERS—Territorial Selling Rights are being rapidly ass

Inasmuch as every motor operates within certain inflexible mechanical limits, and inasmuch as every oil possesses certain inflexible chemical tests, the selection of the best oil is merely a question of selecting the one with the best tests. Nothing more.

There are different tests, but a very simple one is the gravity test, which shows how much carbon an oil contains.

It is a well-known scientific fact, for instance, that carbon in a motor oil is objectionable—and that the oil with the least carbon will (other things being equal) be the best.

June 26, 1913

It is an equally well-known scientific fact that the amount of carbon in an oil is proportionate to the weight or "gravity" of the oil. The lighter the gravity the less carbon the oil will contain. *Even those who are only superficially familiar with these things know that gasoline with a light gravity contains less carbon than gasoline with a heavy gravity.*

It is not difficult to find out which of any two oils has the lightest gravity and contains the least carbon. Simply take two samples of oil in glass bottles (Invader Oil and any other) and pour the other oil into the Invader Oil. *The other oil will sink to the bottom.*

... carbon, and carbon is the thing that causes trouble.

Of the many oils being called to your attention, Invader Oil has the lightest gravity. It contains the least carbon. It is the best because its tests are better.

I-O-C GEAR OIL is the only oil ever manufactured especially and exclusively for the lubrication of Automobile Transmission Gears. Write for prices and descriptive booklet.
